[January 20, 1881.

THE
JOURNAL OF HORTICULTURE,
COTTAGE GARDENER,
AND
HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING POULTRY, PIGEON,
AND BEE-KEEPING.

CONDUCTED BY
ROBERT HOGG, LL.D., F.L.S.

Established

in 1848

VOLUME I. THIRD SERIES.

JULY TO DECEMBER, 1880.

LONDON:
PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

1881.

LONDON :
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

NEVER since the Journal was established have we received so many letters of approval as during the year that has just closed, and our first duty is to thank the writers of them for their pleasant expressions. A great number of these were consequent on the enlargement of our pages—a change that has proved as welcome to our readers as it has been satisfactory to ourselves. The volume to which the accompanying Index refers contains a hundred pages more than the one preceding it.

Every subject connected with the garden has been treated by competent writers. Nearly every county in England has contributed to the volume; Ireland, Scotland, and Wales are worthily represented, while correspondents from the continent of Europe, America, India, and the Colonies have shared in its completion.

We rejoice in a wide, rich, and sympathetic constituency—in writers as skilful as they are ready to impart information; in readers appreciative; in questioners anxious for information, and in assistants who can answer them usefully.

The opening year is cheerful to us, and the more so that we can record, without any special effort having been made on our part, an unexpected influx of new subscribers. We can only account for this in one way—that those who have benefited by their weekly fare have desired that others should benefit also, and have thus brought the Journal to the notice of their friends.

This friendly generous spirit is much valued by us. The best return we can make is to strive to be even more useful—more ready, if possible, to aid those in difficulty, to employ the means at our disposal to render gardens and other home adjuncts more profitable and enjoyable than they have been before.

How far we shall succeed in our aim and object depends greatly on our friends. In them we trust, and our *thirty-three-years'* experience of readers and writers inspires us with confidence that we shall not trust in vain, and that their aid and our efforts will not be fruitless.

WOODCUTS.

INDEX.

- ABIES DOUGLASHI**—transplanting, 373; utility of, 373. *A. Smithiana*, 438
- Abutilon** insignis, 55; *A. Thompsoni*, 335
- Acacia melanoxylon**, 523; *A. pubescens*, 447
- Acæna microphylla**, 212
- Acanthus latifolius**, 255
- Acer Negundo variegata**, 123
- Achimenes**, culture, 195
- Acorns** for cows, 364; poisoning by, 451
- Adiantum Bausei**, 144; *A. Capillus-Veneris* var. *cornubiense*, 396; *A. farleyense* unhealthy, 424
- Advantages** of a home farm, 295, 316, 339, 383, 426
- Æschynanthus grandiflorus**, 350
- Agapanthus**, planting, 292
- Agave horrida**, 170
- Ageratums**, culture, 335; propagating, 336
- Agricultural disasters** in Kansas, 362; prospects, 129, 318, 340, 362, 385; returns, 200, 406
- Agricultural (Royal) Society**, report of meeting, 450, and meeting of Council, 540, 564
- Agriculture**, future of, 201
- Aleyrodes vaporariorum**, 601
- Aloe distans**, 535; *A. Greenii*, 399; *A. mitchellii*, 535
- Alpine plants**, dividing, 245
- Alsophila australis** unhealthy, 222
- Alternantheras**, wintering, 358. *A. paronychioides aurea*, 116
- Amaryllises**, culture, 195, 290
- Amateurs**, glass structures for, 462, 550
- America**—cut flower trade in, 169; food production in, 225; Hop products, 428; mortality of cattle from, 225; Potatoes in, 362
- American and Canadian food supply**, 385; dairy industry, 472; farming, Messrs. Read & Pell's report, 200; grain trade, 340; harvest, 174; Wheat for England, 385
- American blight** on Apple trees, 380; destroying, 172, 511
- Amorphophallus Rivieri**, 459
- Anacharis alsinastrum**, 306
- Anemone**, sowing seed, 113. *A. alba* and *A. alpina*, 414; *A. alpina* var. *sulphurea*, *A. angulosa*, *A. apennina*, *A. baldensis*, *A. blanda*, *A. coronaria*, *A. dichotoma*, and *A. hepatica*, 415; *A. japonica*, 189, 326, 369, 415; *A. japonica alba*, 189, 415; and *A. nemorosa*, 416; *A. narcissiflora*, *A. palmata*, *A. pavonia fl.-pl.*, *A. Pulsatilla*, *A. ranunculoides*, *A. Robinsoniana*, *A. stellata*, *A. stellata fulgens*, *A. sylvestris*, *A. trifoliata*, and *A. vernalis*, 437
- Angræcum Kotschyi**, 352; *A. Scottianum*, 71
- Aniseed Tree**, 79
- Annals** for spring flowering, 197, 242
- Anthomyia Betæ**, ravages of, 318
- Anthurium Andreanum**, 46, 483; *A. Schertzerianum*, 78; *A. Warocqueanum*, 459
- Antler moth**, 61
- Ants v. paraffin**, 79
- Aphides**, increase of, 487
- Apiarian exhibitions**, 541
- Apiary**, a successful Vermont, 406
- Agriculture**, the professorship of, 298
- Aponogeton spathaceum** var. *juncum*, 199
- Apples**—at Chiswick, 343; for market, 402; good culinary for succession, 468; in Worcestershire, 570; large, 579; stocks for, 489; weights of, 506. *Benoni*, 279; *Early Harvest*, 245, 261; *Ecklinville Seedling*, 589; *Sam Young*, 336; *Schoolmaster*, 596; *Small's Admirable*, 359; *The Lady*, 126
- Apple trees**—American blight on, 380; for orchard, 380; for walls, 380; manuring, 580; removing American blight from, 16; planting, 367; pruning, 511; which canker and which do not canker, 454
- Apricot branches** dying, 255
- Apricots** for walls, 389
- Aquilegia cærulea**, 118; *A. juncunda*, 239; *A. Skinneri*, 71
- Arable land**, manures for, 383
- Araucaria imbricata** in Scotland, 299
- Arbutus Unedo**, 461
- Arietis aspera**, var. *arborescens*, 598
- Arrangement** of hot-water pipes, 558
- Arsenic** for destroying weeds on walks, 424
- Artichokes (Globe)** from seed, 308; Jerusalem, 380
- Artificial flowers**, 285
- Artificial incubation**, 175
- Artocarpus Cannoni**, 553
- Asparagus**—dying, 511; fallure, 568; forcing, 469; how I failed to grow it, 503; how to grow, 543; soil for, 527
- Asplenium cicutarium**, 439
- Astelma eximium**, 574
- Aster Amellus**, 325; *A. novæ-angliæ*, 325; Mr. Lee's seedling, 351
- Auk**, Great, high price of eggs of, 40
- August**, plants to flower in, 293
- Auriculas**—autumn-flowering of, 588; culture of, 35, 446, 545; from seed, 135, 162; wintering, 346
- Australian vegetables** in, 242
- Australian Blackwood Tree**, 523
- Australian forest trees**, 213
- Australian sheep station**, 177
- Autumn**—cultivation, advantages of, 104, 126; planting, 395
- Autumn-flowering plants**, 276
- Aviary** in greenhouse, 222
- Azaleas**—at Chiswick, 343; culture, 102, 268, 400; repotting, 35; stopping growths of, 43
- BALLARAT HORTICULTURAL SOCIETY**, 528
- Bankfield**, Liverpool, 136
- Bantams**, Red Game, 225
- Barley**, malting for feeding cattle, 427
- Baskets**, plants for, 292
- Bath and West of England Society**, report of Council Meeting, 127, 564
- Battersea Park**, 209
- Beans**—forcing French, 197; kidney, notes on varieties, 323. *Carter's Leviathan*, 232; *St. Ignatius*, 149
- Bedding plants**, propagating, 148, 336
- Bedfordshire**, a day in, 98, 121
- Beds**, filling for, winter, 401
- Bee-keepers**, report of Congress of German and Austrian, 583, 606
- Bee-keeping**—cottage, 341; in Paris, 83; new and old practices, 249, 319, 451; successful, 407, 520, 605
- BEES**—
And Clover, 450; and Heather, 452; attacked by wasps, 176; deserting hive, 496; driving, 154, 274; feeding, 520; feeding driven, 176; flowers for, 274; hints for safe wintering, 540; how to Italianise, 274; in conservatory, 511; in north of Ireland, 586; in Nottinghamshire, 541; in winter, 452; killing, 320; large hives of, 320; Ligurian v. English, 430; notes, 429; not taking syrup, 474; on Dartmoor, 202; on the moors, 541; protecting, 451. *Queens*, colour characteristics of Ligurian, 130; chase, 407; piping, 41; purely mated, 129. Removing bees from a tree, 130; transferring, 20; uniting, 274; wintering transferred, 542, 585
- Hives**—American mode of removal, 20; anti-robbing porch for, 363; bar-frame, 493; artificial foundations in straw, 474; bee moth, destroying a, 408; Dalbeattie bar-frame, 541; dead grubs in, 84; how to divide stock in a frame, 542; improved straw, 566; products of bar-frame, 451, 474; space between bars and cover of, 342
- Honey**—English v. foreign, 495; harvest of 1880, 273, 385; Heather, 473, 565; keeping, 342; season in Scotland, 342
- Stocks**—Converting stocks in skeps into stocks in frame hives, 250; dwindling, 130; how to divide in a frame hive, 542; making the most of weak, 407; treatment of foul-broody, 341
- Miscellaneous**—Artificial comb foundation, 61, 84, 177, 201, 225, 474, 519; fixing, 226, 341. Brood, transferring, 154. Combs, crooked, 542; destroyers, 535; draining, 496; new and old, 107. Drones, utility of, 225. Experiences with comb foundation, 107, 153. Experiments with foundation, 41. Foul brood, a fight with, 363. Foundation fixers, 20; fixing in frames, 341. Galleries, 565. Grubs, white carried out, 130. Management, routine of, 388. Methylin, 130. Pettigrew's, Mr., challenge, 520. Season of 1880, 420. Swarming, extraordinary, 153; facts about, 42; much, 108; preventing excessive, 20, 83. Syrup, preserving, 430. Wax mite and moth, 565
- Beet**, Egyptian Turnip-rooted, 285, 344; storing, 378
- Begonias**—for winter, 78. *Taberosa* as bedding plants, 347, 350; at Reading Nurseries, 99; propagating, 57, 221; wintering, 221. *B. lucida*, 103; *B. semperflorens grandiflora*, 574; *Suttons' seedling*, 189. See *Plants Certificated*.
- Berberis buxifolia**, 120
- Bignonia capreolata** var. *atro-sanguinea*, 120
- Birds**—breeding, 39; mules and hybrids, 39; notes on, 435, 459, 530
- Blackbirds**, more about, 486
- Blackwood Tree** of Australia, 523
- Boilers** for heating vinery, 172
- Bolbophyllum Beccarii**, 191, 237
- Border**—a cheap perennial, 64; a gay, 21; flowers for, 22, 49, 118, 283; making and furnishing an old-fashioned flower, 387
- Botanic (Royal) Society's evening fête**, 28; visit to gardens, 100
- Bouquet** presented to the Lord Mayor, 416; Italian, 594
- Bouvardias**, culture, 401; and value of 189. *B. Bridal Wreath*, 433; *B. Dazler*, 464
- Boxes** for exhibiting cut flowers, 150
- Brahmas** as mothers, 318
- Bredia hirsuta**, 328
- Briers**, raising seedling, 468
- Brisbane Botanic Gardens**, Queensland, 422
- Bristol Channel Observatory**, proposed, 540
- British Bee-keepers' Association**—report of Committee meeting, 200, 519, 534; and of quarterly conversazione, 429; tent at Clonmel, 178
- Broccoli**—in Cornwall, 528; laying-in, 443; planting, 55; transplanting winter, 134. *Glibet's Cabbage*, 416
- Brookhurst**, Manchester, 73
- Brood**, transferring, 154
- Browallia elata**, culture, 446
- Brussels Sprouts**, 336, 374; culture, 547; cutting tops, 555
- Bucklandia populnea**, 170
- Budding**, flute, 49
- Buffalo horn manure**, 344, 383, 447
- Buildings**, a new mode of heating, 593
- Bulbs**—and bedding, 6; culture, 232; Dutch, 252; in beds, 370, 401; packing for New Zealand, 79; potting, 379, 401; storing, 16; varieties, 252
- Bullfinches**, trapping, 530, 556
- Burning clay**, 419; and soil, 380
- Butter** at Clonmel Show, 199; grain and butter-making, 249; Irish, 472; making, 383
- Buttercups** on pastures, 23, 40
- CABBAGE**—culture, 220, 243, 312; sowing, 56, 85, 196. *Ellari's Early*, 116
- Calanthes**, compost for, 511
- Calceolarias**—culture, 227, 335, 446; of herbaceous, 601; sowing seed, 196; striking cuttings, 313
- Calochortus pulchellus**, 530
- Camellias**—buds abnormal, 358; culture, 79, 268; disbudding, 314; leaves spotted, 35; repotting, 148; setting buds of, 48
- Campanula fragilis**, 129
- Canadian products**, 519
- Canaries**—afflicted, 452; how long will they live? 318; songless, 439; treatment in olden times, 224
- Cannas**, culture, 335; storing, 337
- Cape Gooseberry**, growing in pots, 16
- Capsicums** at Chiswick, 236
- Carnations**—at Christmas, 591; culture, 545; setting-up and judging, 64; planting and potting, 346
- Carpet beds** in autumn, 372
- Carrots**—storing, 378. *Suttons' Champion Shorthorn*, 3
- Catalpas**, uses of, 580
- Catchfly**, 118
- Cattle**—American dairy, 540; breeds of adapted for dairy farming, 425, 448, 469, 490; Highland, 385; malting Barley for feeding, 427; mortality of from America, 225; shed accommodation for, 270, 293, 314
- Cattleya crispata** at Burston, Notts, 149, 180. *C. gigas*, 71; *C. Mar-tersoniae*, 352; *C. superba*, and *C. virginialis*, 71
- Caniflowers**—culture, 56, 312, 446; sowing, 86, 196, 219. *Carters' Delance Extra Early*, 3
- Ceanothus latifolius**, 284
- Celery**—culture, 35; earthing, 196; hollow, 523
- Celery fly**, 16, 36, 76, 115, 116, 132
- Cereals**—acreage of, 406; pedigree in, 17
- Cereus grandiflorus**, flowering of, 28; fruit of, 36
- Charlwood House**, 526
- Cheese factories**, early progress of in England, 40
- Cheese**, manufacture of foreign, 152
- Cheirostemon platanoides**, 511
- Chelsea**, an hour at, 590
- Cherries** for walls, 380; Morello falling, 17
- Cherry house management**, 124, 356, 467, 532
- Cherry trees**, forming pyramid, 490
- Chicago fruit trade**, 533
- Chickens**—buying exhibition, 271; drooping, 202, 274; dying, 542; feeding, 202; gapes in, 225; not thriving, 474; suffering from roup, 154
- Chimonanthus fragrans**, pruning, 149
- Chionographis japonica**, 170
- Chiswick Gardens**, 139; a chapter on, 342; vegetables at, 461
- Chlora grandiflora**, 255
- Christmas**, seasonable notes on, 567
- Chrysanthemums**—against walls, 460; at Ewell, 528; culture, 269; for conservatory decoration and exhibition, 279; Mr. Henslow's lecture on, 465; in the open air, 511; notes on, 78; outdoor in Paris, 376; propagating, 534; stopping, 269; training, 269; wintering, 314. *C. Etolle d'Or v. C. segetum*, 284; *C. frutescens*, culture of, 125; *C. lacustre*, 416; *C. Lady Selborne*, 460; *C. Lilac Gem*, 594
- Churchyard**, trees for, 558
- Cinchona cultivation** in Bengal, 373
- Cinerarias**—culture, 227, 315, 443; destroying insects on root, 245; potting, 148; sowing seed, 196
- Ciræa alpina**, 190
- Citrus trifoliata**, 3-8
- Clark**, Mr. James, autobiography and portrait of, 485
- Clay**, burning, 419
- Clematis Davidiana**, 164; *C. Star of India*, 380
- Climbers** for conservatory, 447; and for exposed situation, 424
- Clomenocoma montana**, 552
- Clonmel**, tent of the British Bee-keepers' Association at, 178
- Clover**—and bees, 450; analysis of hay, 536; and of roots and soil, 559; as a preparatory crop for Wheat, 535, 559

- Cobaea penduliflora, M. Ernst's observations upon the fertilisation of, 9
 Cochins as mothers, 318
 Cockerel, scurf on head of, 364
 Cocoa-nut fibre refuse, uses of, 365, 458, 511
 Coffee disease in Fiji, 237
 Colchicus—pruning, 380; varieties of, 86, 87; C. Mrs. W. M. Shirreff, 262; C. Pompadour, 142; C. Sowter, 54
 Coleworts, culture of, 35
 Colletia cruciata, 553
 Comb foundation—artificial, 61, 84, 177, 201, 226, 474, 519; experiences with, 107, 153; experiments with, 41; fixing, 226, 341
 Combs—crooked, 542; destroyers, 565; draining, 496; new and old, 107
 Common sense in gardening, 3
 Congress of German and Austrian beekeepers, report of, 586, 606
 Conifers for screen, 380
 Conservatory in November, 436; shading, 489
 Cornflowers, culture of, 534
 Corn, pedigree, 40
 Costmary, 222
 Cottagers' Kale, 601
 Covent Garden Market, flowers at, 574
 Cows—acorns for, 364; dairy management and food for, 542; feeding milk, 83; salt for dairy, 586. Kerry, 18; selection and breeding of, 105
 Crinum Kirkii, 308; C. purpurascens, 529
 Crocuses, potting, 379; Indian, 461
 Cropping, rotation of for heavy or mixed loamy soils, 153, 173; and for strong soil, 172
 Crops—acreage of green, 428; in the midlands, 60; prospects, 106; successional, 124, 132, 163
 Croton Stewarti, 458. See *Plants Certificated*
 Crousse's, Mous., nursery at Naucy, France, 169
 Crystal Palace, visit to, 100
 Cucumber house management, 518
 Cucumbers—culture, 16, 77, 78, 124, 171, 220, 268, 312, 356, 400, 467, 557; gunning, 601; not swelling, 149; not thriving in greenhouse, 17; old plants, 325, 369; planting, 403; producing early, 359; raising, 403; thrips on, 16; unhealthy, 80
 Cultivation of land by animal power, 580
 Cuphea selenioides, var. Zampari, 329
 Currant bushes, moss on, 489
 Custard Apple, sowing seed of, 535
 Cyclamens—culture of, 467; potting, 103, 148; unhealthy, 314. C. persicum, culture, 350, 446; and sowing, 292
 Cypella caerulea, 142
 Cypripedium variegatum, 352, 460
 Cypripedium insignis, 413; twin flowers of, 534; C. Fairianum, 465; C. Morganianum, 54
 DAHLIAS—culture, 335, 546; good, 234; varieties at Slough, 189, 234. See *Plants Certificated*
 Dairy farming—breeds of cattle adapted for, 425, 448, 469, 490; industry, 106; American industry, 472
 Daisies, Michaelmas, 325
 December flowers, 544

JULY 1—7.

The following Horticultural Shows will be held during the week:—

1	TH	Shrewsbury (Roses); Richmond; Canterbury (Roses); Tiverton,
2	F	Timbridge Wells. [Brentwood, and Highgate.
3	S	National Rose Show, Crystal Palace; Southgate.
4	SUN	6TH SUNDAY AFTER TRINITY.
5	M	
6	TU	Oxford (Roses); Maidstone (Roses); Boston. [bledon.
7	W	Fareham and South Hants; Hereford (Roses); Beverley; Wim-

TO OUR READERS.

THE present number is the commencement of an enlarged series of this Journal. Upwards of thirty years ago the *Cottage Gardener* was first published, and received a welcome such as its promoters scarcely anticipated. Designed to popularise horticulture, to impart practical instruction to amateurs, to render gardens more profitable, and other adjuncts of home more enjoyable, it fulfilled its purpose in a remarkable manner. The advance that ensued in the culture of plants, fruit, and vegetables led to a demand for literature of a higher class; this was in due time provided, on the principle that as our patrons had contributed to the prosperity of their favourite periodical they should also share in its advantages: consequently our pages were considerably enlarged.

Nearly twenty years have elapsed since then, and during that period the *Journal of Horticulture* has attained a healthy progressive growth, has found its way into many thousands of homes in our own land, has spread into every important colony of the British Crown and every nation where horticulture is practised and cherished. Recognising this fact, we feel that the time has arrived when our great and almost world-wide constituency should further benefit by that which they have aided to establish, and hence without enhancing the price we again enlarge and improve these pages. As in the past so in the future, we shall not give prominence to subjects essentially speculative and sensational, but shall rather seek to impart information that will be serviceable; and if we can render gardens still more satisfactory to their owners and improve the condition of gardeners old and young we shall be content—our labour will not be fruitless.

Our desire is to see horticulture and all who are engaged in it prosper, and with the continued assistance of our many friends and able coadjutors we hope to have a large share in effecting this object. Believing that what we are justified in describing as a high-class paper, issued at a price within the reach of all who really cherish their gardens, will contribute to the result indicated, we submit the Journal in its present form, in full confidence of securing public approval.

CROSS-FERTILISING AND RAISING ROSES
FROM SEED IN ENGLAND.

R. ELLWANGER, of the firm of Ellwanger and Barry, Rochester, N.Y., who is doing much to elucidate the origin of American and English Roses, having requested information respecting the varieties raised by me, I have been induced to look up what I have effected in that direction; and as Mr. Bennett's recent success in crossbreeding the Rose has created considerable interest in the subject, perhaps even the record of unprofitable work may be of advantage to those who propose entering on the same field. By way of preamble, therefore, my advice to all who desire to do so, is not to carry on their operations without the aid of glass wherever such means are available, for two of the great secrets of success in obtaining Rose seed are ripe wood and a dry atmo-

sphere, conditions not always attainable in England without the aid of glass and artificial heat, and undoubtedly much of my labour was thrown away for want of proper protection against the vicissitudes of our climate, and many valuable acquisitions may consequently have been lost; for as the majority of the best Roses are very double and really botanical monstrosities, this abnormal fulness of petals tends towards decay of the generating organs by retaining surplus moisture.

My first attempt at crossbreeding the Rose was in 1857, when, *inter alia*, I fertilised H.P. Général Jacqueminot with the old white Damask Maiden's Blush. From this cross I obtained a very pretty light carmine variety, remarkably sweet and of good form, but not sufficiently large for a show Rose. I gave the stock some years afterwards to Mr. Ward of Ipswich, who had been working in the same direction, but I do not think he found it good enough to send out. From this start, however, I derived sufficient encouragement to induce me to proceed, and in the seven years from 1858 to 1864 I fertilised, marked, and recorded nearly five hundred blooms, crossing, recrossing, and intercrossing most of the best H.P.'s, Teas, Bourbons, and summer striped Roses of the period; and amongst the more remarkable of the results I obtained a vigorous-growing, semi-double, satiny-pink flowered seedling from T.N. Gloire de Dijon × H.P. Souvenir de Comte Cavour (a bright red Rose), the offspring being a good seed-bearer, the flower almost scentless, and the plant in most respects partaking more of the Hybrid Perpetual than of the Tea character, the foliage and growth showing but little of the latter type. From naturally fertilised flowers of this Rose I have raised seedlings showing more of the Tea blood than their parent, some coming single white and apparently pure Teas, others dark red and very double H.P.'s. By crossing Bourbon Louise Odier × striped Provence old Tricolor, the offspring was a summer Rose with the spring foliage distinctly striped with yellow, the variegation, however, invariably disappearing in the summer as the foliage matured. The flower was pale pink without any appearance of variegation. Many of the blooms fertilised were abortive, and either never set at all or produced hips without seeds, and, as is usually the case, numbers of the seedlings succumbed to weakness of constitution. Not a single Rose, however, of any commercial value or good enough to be sent out came from these attempts. In 1865, however, I determined to make more extended efforts in crossing the Rose, and as a further inducement and encouragement for me to proceed, the York Horticultural Society offered annually a prize for the best English-raised white Hybrid Perpetual Rose. Accordingly in that year I fertilised, marked, and recorded upwards of four hundred blooms, chiefly H.P.'s and Teas, and in 1866, 1867, and 1868 upwards of one hundred more. From amongst the varieties crossed in 1865 I obtained a hip containing seven seeds by fertilising H.P. Madame Vidot × Virginal. One seed only vegetated, and this produced H.P. Princess Louise, a good hardy, creamy-white garden Rose, sometimes tinted pink (sent out by Messrs. Paul & Son). This, however, failed to satisfy the requirements of the schedule of the York Horticultural Society as a white Rose. There is a likeness in this Rose to Mabel Morrison, a bud sport with white flower from Baroness Rothschild. By crossing H.P. Louise Peyronny × Victor Verdier I aimed at getting a flower of the largest size,

and this I secured in H.P. Prince of Wales (sent out by Messrs. Paul & Son), but unfortunately its thinness of petal and want of a stout external guard render the flowers liable to fall open and to appear somewhat coarse. These are the only two fairly good Roses which have, I believe, at present been distributed from upwards of one thousand crosses! but good results have been obtained and will probably be shortly forthcoming from crosses between 1864 and 1868—viz., H.P.'s Comtesse Chabillant × Jules Margottin and Anna de Diesbach; John Hopper × Sénateur Vaisse; Gloire de Santenay × Madame Julie Daran, Prince Camille de Rohan, and Beauty of Waltham; Lord Raglan × Charles Lefebvre and Maurice Bernardin; Jules Margottin × Sénateur Vaisse, François Lacharme, and Bourbon Louise Odier; Charles Lefebvre × Lord Raglan, Sénateur Vaisse, Mons. Boncenne, Prince Camille de Rohan, André Leroy, Alfred de Rougemont, and Madame Furtado; Louise Peyrouny × H.C. Charles Lawson, Victor Verdier, and B. Louise Odier; H.C. Charles Lawson × H.P. Olivier Delhomme; Bourbon Baron de Noirmont × Sénateur Vaisse; Madame Victor Verdier × Charles Lefebvre; La Ville de St. Denis × Marguerite de St. Amand; Mons. Boncenne × Charles Lefebvre, Mdle. Bonnaire (all H.P.'s), and Striped Gallica Village Maid. Some of the offspring of the above crosses have from inherent weakness disappeared, and others which have exhibited more or less novel or valuable traits are in the hands of Mr. Charles Turner of the Royal Nurseries, Slough, who will probably in due course, and when thoroughly tested, introduce them to public notice.

In the course of my operations the anthers only of those flowers were previously removed in which there appeared special risk of self-fertilisation; but cross-fertilisation was generally effected only on such flowers and when in such condition as to be practically safe from self-fertilisation. Since 1868 I have chiefly discontinued the raising of seedling Roses from artificially fertilised flowers, and have devoted my attention to the selection of hips from naturally fertilised flowers of the best varieties only, having long since arrived at the conclusion that by the latter means more certain results may be obtained, especially where good shape and beauty of flower are desired, as the different types of beauty in the Rose are numerous, each being excellent in its own particular character, but when any of these types are combined coarse or heterogenous flowers may be expected to result. Most of our garden Roses have also been so much interbred that there is a great tendency in the offspring to revert to one or other of their ancestral types, rendering the results from cross-fertilisation too precarious and unreliable to be remunerative. Mr. Bennett, however, is opening-up somewhat new ground in crossing the Teas with H.P.'s, and with his appliances, skill, and intelligence all brought to bear, some novel and valuable hybrids ought deservedly to crown his exertions.

It is, however, scarcely credible that such a practical people as the French, who, although they may not always grasp our tastes as readily as they do our purses, but who are at least as prompt and expert in the cross-fertilisation and hybridising of plants and flowers as we are in England, should so universally have neglected to resort to or to continue to use similar means with the Rose unless more certain or remunerative results were otherwise attainable; and I can only arrive at the conclusion that experience has taught our neighbours as it has myself, and I believe others who preceded me in this country (including Mr. Wm. Paul), which is the more profitable mode; and it must not be forgotten that the immense advance which has been made in the garden Rose, especially in the Hybrid Perpetual class, during the last three decades is largely due to French exertions, and has been attained, practically only, by means of self-fertilisation. The following Roses raised by me in 1864 were from seed of naturally fertilised flowers—viz., H.P.'s Annie Laxton from Jules Margottin; Marchioness of Exeter, probably also from the same parent; and Empress of India I believe from Triomphe des Beaux Arts, and not from Louis XIV., of which it appears to be a vigorous prototype. In 1869 I raised H.P.'s Mrs. Laxton, probably from Mdle. Victor Verdier, and Charles Darwin from Madame Julie Daran, this being the dark H.P. Rose of Bourbon blood *par excellence*, of which I sowed the seed in that year. All the above

were sent out by Messrs. Paul & Son. The parentage of H.P.'s Richard Laxton sent out by Mr. C. Turner, and Dr. Hogg in the hands of Messrs. Paul & Son, I regret being unable to identify; but with a large and continually increasing number of seedlings I have found it impossible to keep even the year's results in all cases distinct.

Seedling Roses are very uncertain as to the period of showing their first blooms, some flowering when little more than 2 inches high, and within two or three months from the seed being sown, and others, although often eventually proving good Perpetual Roses, do not show bloom for several years. I have now seedlings of the current year showing bloom. My crop this season consists of upwards of one thousand seedlings grown on a bed containing about 2 square yards; most of these are already planted out, and several of them I hope to bud, bloom, and primarily test before winter. In the ordinary course at least one-half will probably disappear before next year from delicacy of constitution. These I shall not regret, as a winter's exposure will save an immense amount of anxiety and some labour for the care of what would have proved to be only consumptive and sickly progeny. All seedling Roses before being distributed should be fairly exposed during one winter at least, and our race of Roses would eventually become hardier and more vigorous. The practice ought to be a *sine qua non* with all raisers, some discretion being exercised as regards the variety and the situation.—T. LAXTON, Bedford.

TO ENGLISH HORTICULTURISTS.

WE have been requested by the Syndicate of the Ghent nurserymen to publish the following address. We may also mention that the Council of the Royal Horticultural Society have sent an urgent remonstrance to Lord Granville at the Foreign Office, calling attention to the great injury that will be done to the nursery trade if the terms of the Convention are enforced:—

"You are no doubt aware that in order to prevent the invasion of the Phylloxera a Convention was signed at Berne on the 17th of September last, by the Plenipotentiaries from the Swiss Confederation, Italy, Spain, Portugal, Austria, Germany, and France, to the effect that in future all horticultural produce would only be allowed to be imported into the countries in question under certain restricted conditions, one of which stipulated that the roots of all plants must be completely divested of soil, which in fact signifies a total exclusion of plants.

"Italy and Spain, finding the terms not sufficiently stringent to satisfy their requirements, have refused to ratify the Convention and forbidden the importation of all plants; while the Swiss Confederation interdicts the introduction of all horticultural produce coming from countries forming no part of the Convention, even when such sendings are accompanied by a consular certificate, which is deemed an insufficient warrant.

"If these severe measures are maintained or put in force it is evident that they will cause the unavoidable and absolute ruin of many horticultural traders, and inflict a lasting injury on horticultural industry in all countries where it flourishes. No other branch of industry than this requires, in fact, a more vast and wider field for operation; and hence in the presence of such an impending calamity we, the Ghent nurserymen, founded a committee with the object to protect by all just means the interests of our threatened industry. This committee immediately summoned the Belgian nurserymen to a plenary meeting, explaining the gravity of the situation, and a petition to that effect was sent forthwith to the Foreign Office. The Ghent delegates undertook to instigate a public interpellation in the Belgian Parliament; while a special deputation, in order to support the petition and to set off the intense danger threatening the horticultural industry, conferred with the Secretary for Foreign Affairs.

"Notwithstanding all the activity displayed in the matter by the Ghent Committee the last records obtained seem to be unfavourable, more particularly so from Germany, whose frontiers it is said will be closed on or about the 1st of July. This fact is of highest importance, as it may be supposed with some certainty that the other countries engaged in the Convention will act in the same way as Germany.

"The Committee considered the interests put forth forming a part of yours; and the danger menacing the Belgian horticulture will also fetter the progress of your country, therefore thinks it quite essential on your part to take immediate and serious action in order to present a petition to your Government, either through

the medium of a scientific or horticultural committee, with a view of obtaining a modification of the Berne Convention, especially to claim the revision of paragraph iv. article iii., requiring that the roots of all plants must be divested of soil, which is the worst feature of the recently enacted regulations, to prevent the spread of the Phylloxera. "A Government like that of England, a country of first rank for industry and commerce in general, and occupying a great position in horticulture, could do much to stay the danger in view, more especially as it plays a preponderating and influential part in all important questions which eventually must be settled through diplomacy."

"We are sure that if all nurserymen of the countries menaced by the Convention act in a body our just cause would find many sympathetic supporters amongst the influential class, and perhaps ward off the blow dealt against our industry."

"For the Chambre Syndicate of Ghent Nurserymen,

"The President,

"A. VAN GEERT."

COMMON SENSE IN GARDENING.

IN a recent number of the *Journal of Horticulture* of the last volume, page 462, I have been reading an article entitled "Fashion in Gardening" from the able pen of "WYLD SAVAGE," who recommends us to follow common sense rather than fashion in gardening. This is very good advice; but all gardeners, especially when any change of system is adopted, require patience as well as common sense; and if "WYLD SAVAGE" expected by a large and apparently indiscriminate outlay of money one year to reap a glorious display of gay bloom the next, it is not surprising that some disappointment has been the result. There is an old saying, that the difference between a lady and her maid is, that the one uses fashion, the other abuses it; and I think if we lovers of gardens followed the ladies, we might have our gardens as gay and far more beautiful than they are at present.

The objection to the bedding-out system seems to me, not in employing tender plants, nor yet in employing them in masses,—for nearly all flowers look best in quantity—but in sacrificing valuable and picturesque plants to them. As regards the geometrical system, no one who appreciates the beauties of Nature or the smallest affection for his flowers could endure to see his plants with every bloom carefully sheared off and the whole patted level to resemble a gaudy carpet, so I will leave that system out of the list. The herbaceous system on the whole is the most natural, and therefore the best. But we need not follow it blindly. Probably no two gardens are adapted to exactly the same style; the owner's purse, taste and time for gardening, as well as the situation and soil of the garden, are sure to vary.

My own style of gardening I call the woodland style, my aim being to have my garden resemble those very bright little bits of wood that we often come upon when there is a little break in a forest. The expense and trouble are very small, the result being the garden is green and fresh all the winter with Ferns, gay from the earliest spring flowers until July or August. Then I confess to a short interregnum; but in autumn we are bright again. At the present time as I write looking out upon my garden I do not think my list of flowers would equal in number "WYLD SAVAGE'S" despised catalogue, but then they grow in masses. Just opposite as I write is a bank golden with the Welsh Poppy, with peeps here and there under the Poppies of the *Myosotis dissitiflora* still in full bloom, and above all several favourite old Ferns pushing their grand fronds above their surroundings. He calls a *Geum* a poor flower; let him grow masses of *G. cardinalis* and *flore-pleno*, and mix them either with yellow Wallflowers or yellow Poppies, and he will not find his herbaceous borders look dull at this time of the year.

It used to be the fashion to arrange our flower vases with the greatest number and variety of gay flowers that it was possible to cram in, making the whole as level as a child's wool ball; now we employ a third of the flowers, arranged as lightly as we can, with a few Ferns and Grasses to break the level surface, the result being the whole is far more pleasing to the eye, and we can also see each individual flower. Now if, instead of giving up the bedding-out plants we employed them in a similar way, we should find more pleasure and less expense. Plant clumps of the beautiful old-fashioned Ribbon Grass among your flat Pelargonium beds, and edge them with *Tropæolum canariense*, or any quick-growing creeper trained over wire hoops bent to form a sort of basket to take off the dead flat, and you will find the Pelargoniums look as well again, and moreover the Ribbon Grass will last through the winter and shoot fresh to be ready to enliven the earliest bulbs.

"WYLD SAVAGE" has given us some most enjoyable accounts

of the woods this spring, and after all our best teaching must come from them; and to those whose only Ferns are grown in their own garden, and who rarely see a wood, far less a hill, such descriptions are a real treat, and I wish that by common sense and patience his garden may some day be worthy to compare with the woods.—C. A. K.

GOOD NEW VEGETABLES.

Carters' Defiance Extra Early Cauliflower.—The Messrs. Carter are quite justified in describing this new production as "extra early," it being, in my opinion, the earliest Cauliflower in cultivation. On March 14th last I sowed seed of it in a cold frame. When the plants became large enough to handle they were planted out in rows on a south-east border. They were never protected after being planted out, and the heads were ready for cutting three months after the seed was sown—viz., June 14th. It grows so compact that the plants might stand 1 foot apart without being greatly crowded, and the heads are very firm, pure white, and about 4 inches in diameter. Wherever choice extra early Cauliflowers are valued this variety is the one which should be largely grown.

Suttons' Champion Shorthorn Carrot.—This is the most useful early Shorthorn Carrot anyone can grow. Many are too ready to think when they have one variety of Horn Carrot they have as good as any, and need trouble about no other. This is frequently a mistake, as the varieties vary very much. On February 24th I sowed Suttons' Champion Shorthorn, Early English Horn, Early Nantes Horn, and Intermediate, on a south border. All have grown well, but at the present time the first named has roots double the size of any of the others, being about 4 inches in circumference round the crown, of fine shape and splendid quality.—J. MUIR.

LEEDS HORTICULTURAL SHOW.

JUNE 23RD, 24TH, AND 25TH.

"FINE at York, wet at Leeds," was a remark often heard on the Show ground at Leeds last Wednesday, and it appears to correctly express the character of the weather that usually prevails at the two great annual floral gatherings. At York this year the weather was brilliant on the occasion of the *fête*; at Leeds on the opening day of the Show it was little short of miserable, but it cleared towards evening, when large crowds visited the Exhibition in the Horticultural Gardens. The second day—the "money-taking day"—opened with a downpour, which continued with little intermission throughout the day. This is the more to be regretted, since the Society is in a very great measure dependant on gate money, only a comparatively few of the great and busy town being annual subscribers. It is abundantly clear that if the earnest and hardworking directorate of the Society were supported in a manner at all commensurate with their efforts, that an Exhibition worthy of the town and county would be produced, and Leeds Show would undoubtedly become one of the finest of provincial gatherings.

The Show, as in former years, was arranged in a monster marquee—wide, lofty, and nearly 400 feet in length, for the principal plant classes; and two side tents, one for fruit, Orchids, Roses, &c., the other for Pelargoniums and Ferns. Every section of the Show was good; that devoted to groups of plants arranged for effect grand; unquestionably the largest and finest competitive display of the kind ever seen in England. The groups did not, of course, equal in richness the collections of our great nurserymen as exhibited at the principal London shows; but the thirteen conc-like masses of fine-foliaged plants and flowers, arranged with much labour and considerable taste down the centre of the large structure, had a unique effect. The centre of the tent was furnished with specimen flowering plants, which were excellent, arranged on a circular stage, the sides of the marquee being occupied with Fuchsias, Ferns, &c. Grand as this tent undoubtedly was, it is a question if it would not have been still more imposing had a few collections—specimen plants, Ferns, Fuchsias, &c.—been arranged down the centre at wide intervals, the "effect" groups being in the form of semicircles down the sides of the tent. Than of the form indicated no mode of arrangement is more effective and more easily carried out by exhibitors; but whatever the form decided on by committees of shows for groups, it should if possible be stated in schedules.

GROUPS OF PLANTS.—The effect groups, as constituting the chief feature of the Show, demand primary attention. There was an open class for plants not to exceed 300 feet of space, the prizes being £15, £10, and £5; a 150 feet class for amateurs in the county of York, the first prize being a timepiece, value £10, offered by the Mayor of Leeds, Alderman Tatham; and a 100 feet group also for amateurs of the county. In the open class there were seven com-

petitors, the groups being in the form of oblongs, 20 by 15 feet, with rounded corners, the central plants reaching a height of 8 to 12 feet. In this class Mr. Frankland, gardener to J. Barran, Esq., M.P., Chapel Allerton Hall, Leeds, was awarded the chief prize. The centre plant was a fine specimen of *Pandanus utilis*, flanked by Tree Ferns and Palms, and lower down were good pyramid Fuchsias, which stood out clearly from the *Dracenas*, *Crotons*, and similar plants. The front was composed of Zonal and Fancy *Pelargoniums* fully too large, with here and there a new *Coleus*, and rising from these some well-flowered examples of *Saxifraga pyramidalis* showed to great advantage. The margin consisted of *Isolepis gracilis*, small Ferns, *Lobelias*, and *Gloxinias*. *Spiraeas* were interspersed here and there, and such plants as variegated *Yuccas* and *Jacaranda mimosaefolia* gave effect to this free and cheerful arrangement. Mr. Cypher, Cheltenham, followed with a very tastefully arranged collection of valuable plants in admirable condition, the Palms, &c., in the centre being bright and glossy, the *Crotons* in brilliant colour and elegant. The flowering plants, rather too sparse, consisted of *Anthurium Schertzerianum* very fine, *Dracophyllums*, *Ericas*, a few Orchids, and excellent examples of *Eucharises*, *Kalosanthes*, and *Ixoras*. A few of the plants were fully too formal for this mode of arrangement, but they were admirably relieved by others of graceful habit, and the growth was worthy of its position. Third honours went to Mr. Simpson, florist, Selby, with a fine collection but fully too heavy, and the front plants rather too closely packed and level. Mr. Cole, Withington, Mr. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester, and Mr. Harrison exhibited well in this class, and that they secured no place in the prize list is demonstrative of the great excellence of the competition.

In the 150 feet class some charming groups were exhibited, and the Judges had the greatest possible difficulty in awarding the Mayor's prize; the coveted honour, however, eventually fell to Mr. Raper, gardener to J. Rhodes, Esq., Potternewton. The central Tree Fern formed a canopy for a grand mass of *Lilium auratum* and *Dendrobium Dalhousianum*; lower down, Ferns, Fuchsias, *Spiraeas*, and *Dracenas* were picaesingly associated, the front being composed of some of the newer *Coleuses* and Ferns, relieved with *Saxifraga pyramidalis*, the margin consisting of *Lobelias*, *Abutilons*, and *Panicum variegatum*. A few Orchids here and there had prominent positions, and the group on the whole was bright and elegant. Mr. Tuke, gardener to G. Gelder, Esq., Headingley, was an exceedingly close second, the plants being of superior merit to the others—indeed were in admirable condition. Had some of the *Dracenas* and similar plants been brought nearer the margin they would have added to the elegance of the arrangement, which had just a suspicion of formality and packing, and would have turned the scale in its favour. The centre plant was a very healthy and elegant *Cycas*. Mr. Hemming, gardener to H. Oxley, Esq., Weetwood, was an excellent third—a group that would have won easily three years ago. It was full of good plants rather too closely packed; amongst them the old *Diplacus glutinosus* was in fine condition and "told well." The centre plant was a *Cordyline*. Mr. Wright, gardener to Grosvenor Talbot, Esq., Southfield, Burley, Leeds, exhibited a most imposing and remarkable group, but much too formal and laboured to meet with the approval of the Judges, the sides being almost as perpendicular as a wall, starting from the base with pans of *Selaginellas* placed on edge. This formal flower building was finely canopied with the fronds of a fine Tree Fern. John Harrison, Esq., St. John's Grove, Leeds, had a very elegant arrangement, and worthy of an extra prize. As an amateur with a very small garden this exhibitor contributed most meritoriously, but was overpowered by those having greater means at their disposal.

In the 100 feet class Mr. Sunley, gardener to Mrs. Smith, Moorfield House, Headingley, and Mr. Goodchild, gardener to Mrs. Naylor, Potternewton, had the prizes in the order named with very creditable collections.

Nearly every collection would have been improved had some of the taller and elegant plants been brought nearer the margin, rising from a groundwork of Ferns and other dwarf flat plants, and so afforded lightness, elegance, and relief that render groups so artistic.

STOVE AND GREENHOUSE PLANTS.—In the large class for twelve plants in flower the two renowned exhibitors, Messrs. Tudgey and Cole, competed. The former put forth his full strength and won. The plants in these collections have been so often seen and described that it were superfluous to further refer to them here. The amateurs' class for six plants was admirably filled. Mr. Tudgey was again in the premier position with splendid specimens; Mr. Lingard, gardener to H. Sampson, Esq., Bowdon, Cheshire, being an excellent second with *Ixora Colei*, *I. coccinea*, *Dipladenia amabilis*, and *Allamanda Hendersoni*, remarkably fine; a very symmetrical *Vinca*, and a rather loose *Phenocoma*. Mr. Tuke was a very close third, *Ixora Fraseri* being splendid, and a *Dipladenia* very good. Mr. Frankland staged well in this class. The class for three plants call for little notice, being mostly irregular. The first prize was awarded for the most equal in size and fresh, exhibited by Mr. Rollisson, gardener to W. Bateman, Esq., Harrogate, followed by Mr. Wright and Mr. Tuke. Mr. Winterbourne, gardener to Thos. Simpson, Esq., Weetwood, staged the best specimen *Erica*, a very good example of *E. depressa*.

Table plants were fresh and clean and well selected as to size, and the prizes went in the following order—first to Mr. Rollisson, second to Mr. Cypher, and third to Mr. Winterbourne.

ORCHIDS.—These were not numerous, but several bright and healthy examples were staged. Mr. Mitchell, gardener to Dr. Ainsworth, Broughton, Manchester, was clearly in the ascendant with *Cypripedium barbatum*, *Calanthe veratrifolia*, *Aërides Dayanum*, *Thunia Marshalli*, a brilliant mass of *Epidendrum vitellinum majus*, and *Phalænopsis Luddemanniana*. Mr. Rollisson, gardener to Walter Bateman, Esq., Harrogate, was a good second with fresh plants, and Mr. Frankland third. Mr. Mitchell was also first in the class for three plants, and Mr. Sunley, gardener to Mrs. Smith, Moorfield House, Headingley, third. Mr. Hemming, gardener to Henry Oxley, Esq., Weetwood, won the chief position in the single specimen class with a superb example *Cypripedium barbatum*, a charming variety admirably grown. Mr. Cypher, Cheltenham, was second with *Saccolabium Blumei* with two fresh and handsome spikes; and Mr. Raper, gardener to J. Rhodes, Esq., Potternewton, third with a large healthy mass of *Aërides odoratum*.

ORNAMENTAL-FOLIAGED PLANTS.—These were very good indeed, Mr. Tudgey winning first honours with a powerful group—grand Palms, and huge well-coloured *Crotons*; Messrs. Cole being a very close second, the group including the finest example of *Croton Disraeli* we have seen; and Mr. Lingard a good third.

Ferns.—For six stove and greenhouse Ferns Mr. Raper won premier honours with a heavy collection, but the plants irregular in size, ranging from a very large *Dicksonia* to the much smaller but admirable examples of *Adiantum gracillimum* and *Leptopteris superba*. Mr. Lingard was an excellent second with large healthy specimens, and Mr. Cypher a good third. In the class for three Ferns Mr. Winterbourne was placed first with a grand *Cyathea princeps*, *Cibotium Schiedeii*, and *Dicksonia antarctica*, very good. Mr. Tudgey was an excellent second, and Mr. Eastwood a good third. Mr. Ryland had the first position with a very good collection of twelve hardy Ferns, Mr. Naylor being a good second, and Mr. Hodgson third.

ROSES IN POTS.—The display of these was not large, but highly meritorious. In the class for twelve plants Mr. May, Bedale, was placed first with large flat-sided specimens with moderate blooms; and Messrs. Jackson & Co., Bedale, second with smaller vigorous plants with grand exhibition blooms. Some judges would have reversed this decision. For six plants Messrs. Jackson were first, Mr. May second, and Messrs. Pybus & Son, Monckton Moor, Ripon, third, as they also were in the preceding class. Some of the best plants of Messrs. Jackson in 8-inch pots were nearly equal to the best efforts of Messrs. Turner and Paul.

PELARGONIUMS.—These were very fine, and produced a rich effect; but as the display was almost an exact counterpart of that at York, and fully described last week on page 490, it is only necessary to enumerate the chief prizewinners. For twelve Show varieties (open) Mr. May, Bedale, was a good first; Mr. C. Ryland, Aughton, Ormskirk, second; and Messrs. J. Lazenby & Sons, York, third. In the amateurs' class for twelve plants the first and second prizes were won by Mr. Eastwood and Mr. Winterbourne. There was no card to the third lot. Messrs. Lazenby were first with six French and spotted varieties, Mr. Ryland second, and Mr. May third; and for six Fancies the awards went to Messrs. Ryland, Eastwood, and May in the order named. For six Zonals, single, Mr. W. Winterbourne, Mr. G. Winterbourne, and Mr. Hodgson secured the prizes. Double Zonals were not good, the best being those from Mr. Simpson, Selby, who also had the best golden bicolors; Mr. Banks, Selby, having the best tricolors.

Fuchsias were better than we often see them exhibited now, yet were not in by any means first-class condition. Mr. Eastwood was first with six plants—well-flowered one-sided pyramids, 4 to 6 feet high; Mr. Hodgson being second with some better-furnished specimens, others being weak; and Mr. Wright third. The other classes call for no comment.

Gloxinias.—Finer plants have rarely been exhibited than those staged by Mr. Hodgson, gardener to W. L. Jackson, Esq., Allerton Hall, Leeds, and the varieties were also of great merit. Rev. W. G. Gardner, Heworth, York, was an excellent second with varieties of more drooping habit, but large and fine; and Mr. Backhouse, gardener to Dr. Gott, The Vicarage, Leeds, was an excellent third with large healthy plants, but small flowers. Seedling cut flowers from Mr. May were highly commended for their good form and rich and varied colours.

Pans of bedding plants were admirably exhibited by Mr. Simpson, Selby; Mr. Hodgson being second, and Messrs. Lazenby third. The plants as grown in pans 2 feet in diameter had a fine effect.

Ageratum The Queen, exhibited by Mr. Simpson, New Lane, Selby, was awarded a certificate. It is very dwarf and floriferous, the flowers being good and nearly pure white—a very promising variety for bedding purposes.

Mr. B. S. Williams contributed an attractive feature to the Show—namely, a long table of choice and rare plants from the Holloway Nurseries; had more of such plants as these been employed in the groups they would have contributed much to their richness and decorative merit.

FRUIT.

Collections.—Only one collection was staged in the special class of four dishes, but it was a good one, by Mr. Clayton, gardener to J. Fielden, Esq., Grimston Park, Tadcaster, and consisted of a splendid Queen Pine, good Black Hamburgh Grapes, with A Bec Peaches and Violette Hâtive Nectarines. Mr. Clark, gardener to the Marquis of

Ripon, Studley Royal, was placed first in the class for six dishes with splendid Golden Champion and very good Black Hamburg Grapes, a very large Blankney Hero Melon, splendid Castle Kennedy Figs, and good Royal George Peaches. Mr. Clayton was an extremely close second with a superior Queen Pine, fine Muscat and good Black Hamburg Grapes, well-coloured Violette Hâtive Nectarines, a Melon, and rather small Peaches. Mr. Westcott, The Gardens, Raby Castle, was placed third. Dr. Hogg Peaches were fine in this collection, but over-ripe. In the class for four dishes Mr. Clark was again first with Black Hamburg Grapes, Scarlet Perfection Melon, Golden Rathripe Peaches, and Lord Napier Nectarines, all in admirable condition. Mr. Clayton was second, his Pine and Grapes being very good; and Mr. Wallis, gardener to Sir H. M. Thompson, Kirby Hall, Leeds, a close third, Grapes and Cherries being excellent.

Grapes.—The display of these was highly creditable to the several exhibitors. In the class for two dishes Mr. Wallis had the premier position with splendid examples of Buckland Sweetwater and excellent Black Hamburgs. Mr. Westcott was second with well-ripened but not large bunches; and Mr. Thompson, gardener to J. Padgett, Esq., Transfield Lodge, Guiseley, third with larger but less ripe bunches. There were eight competitors. Mr. Johnson, gardener to Messrs. Noble & Ridsdale, Boston Spa, was first in the class for a single dish of Black Grapes with very large and fine examples of Black Hamburg; Mr. Meredith, gardener to W. H. Gott, Esq., Armley, Leeds, being second with smaller bunches of splendid quality, Mr. Wallis being an excellent third. Eight very good dishes were staged in this class. In the corresponding class for white Grapes Mr. Wallis was far ahead of his rivals with Buckland Sweetwater of faultless appearance; Mr. Taylor, gardener to Sir Henry Ripley, Bart., Acacia, Apperley, second with large but not quite ripe Muscats; and Mr. Sunley, gardener to Mrs. Smith, Moorfield House, Headingley, third with the same variety, large but unripe. Mr. Johnson and Mr. Wallis had the prizes in the heaviest-bunch class with large and well-finished Black Hamburgs.

Pines.—The prizes for Pine Apples went in the order named to Mr. Clayton with a splendid Queen; Mr. Faulkner, Woolton Hall Gardens, Liverpool, a good Smooth Cayenne; and Mr. S. Taylor. The Queen Pines staged by Mr. Clayton deserve a special note of approval; they were the finest fruit we have seen this year at any show, being excellent alike in size, shape, and condition.

Peaches and Nectarines.—Peaches were very good indeed. Mr. Faulkner easily won chief honours with superior examples of Belle-garde; Mr. Purdy, gardener to J. T. Leather, Esq., Leavenhorpe Hall, being a good second; and Mr. Sutton, gardener to H. Bentley, Esq., Eshald House, third. In the Nectarine class Mr. Wallis, Mr. Sutton, and Mr. Puzey, gardener to W. H. St. Quintin, Esq., Rillington, York, had the prizes in the order named, all exhibiting well. Mr. Faulkner had the first prize for Figs with a good dish of Panachée. The first prize for Melons was awarded to Victory of Bristol, a fruit of splendid quality with no exhibitor's name attached; Mr. Clark being second with Rauceby Hall, also of superior quality. Strawberries, except the first dish of Dr. Hogg exhibited by Mr. Clarke, were not noteworthy.

CUT FLOWERS.

Messrs. E. Cole & Sons, Withington, Manchester, were easily first with a grand stand, the bunches consisting of Allamandas grandiflora, nobilis, and cathartica, two Ericas, two Aphelexes, three Ixoras, Francisca calycina major, Hoya carnosae, Eucharis, and Dipladenia amabilis. Mr. Rollisson, gardener to Walter Bateman, Esq., Harrogate, had the second prize. For twelve cut flowers the competition was close. Mr. Lingard, gardener to H. Samson, Esq., Bowdon, Cheshire, was placed first with a beautiful stand containing Cattleya Mossiæ, Aërides Dayanum, Dracophyllum gracile, Ixora javanica, Erica Denisoniana, and Anthurium Schertzerianum. Mr. Faulkner was an excellent second, and Mr. Sunley third. Good stands of Zonal Pelargoniums were also exhibited.

Bouquets.—These were much better than are often seen at exhibitions. Mr. Rylance was awarded the first prize for a prize bouquet, and Mr. Cypher second, but the latter was the favourite with the ladies, being less crowded than the other; and Mr. Wright, gardener to Grosvenor Talbot, Esq., Birley, Leeds, was first with a ball bouquet. Table decorative stands were elegant, but not superior.

Roses.—The display of these was very good, the best that were staged up to the date this year. In the class for forty-eight blooms the Cranston Nursery Company well won the first position, Etienne Levet, Avocat Duvivier, La Rosière, E. Y. Teas, Sénateur Vaisse, Marie Baumann, Ferdinand de Lesseps, and Duc de Wellington being in remarkable fine condition. Mr. May, Hope Nurseries, Bedale, was second, many of the blooms having evidently had the shelter of glass and were good. The same exhibitors occupied similar positions in the class for thirty-six blooms. In the amateurs' class for twelve blooms the celebrated cultivator, Mr. T. Jowitt, The Old Weir, Hereford, was an excellent first, staging among others grand blooms of Mons. Noman, Beauty of Waltham, Le Havre, Etienne Levet, and La France, relieved by attractive blooms of Madame Caroline Kuster, Belle Lyonnaise, and Maréchal Niel. Mr. Eastwood, gardener to F. W. Tetley, Esq., Weetwood, was second with smaller blooms. Mr. Jowitt was far in advance of other competitors with twelve blooms; and for twelve Teas the Cranston Nursery Company were the only exhibitors with a stand containing some charming blooms.

Amongst the miscellaneous exhibits we notice skeletonised leaves from Mr. Kaye, Didsbury, Manchester; waterproof plant labels, very useful for nurserymen, from Messrs. Fisher, Clark, & Co., Boston; tubular boilers in various sizes, strong and good, from Mr. Harlow, Macclesfield; and a very light well-constructed span-roof house and frames from Messrs. R. Halliday & Co., Middleton.

The tents during the greater period of the Show were like a quagmire, and Mr. Billborough's efforts were taxed to the utmost to render them passable. Horticulturally speaking, the Show was the finest ever held in Leeds, and had the weather been favourable would unquestionably have been financially successful, whereas under the circumstances it is expected the loss incurred will not be less than £400—a most unfortunate result for the excellent Committee and Secretary, who have laboured with untiring assiduity in producing a Show worthy of their great town and county. With true Yorkshire pluck, we understand they have decided, if possible, to have a supplementary Show in August, and it is strongly hoped that subscriptions will be forthcoming to meet present deficiencies, and add to the reserve fund that is already organised.

STRAWBERRIES AMY ROBSART AND PIONEER.

OF the early Strawberries tried this year at the Experimental Garden Dr. Roden's Amy Robsart has proved itself the finest early, ripening at the same time as Black Prince. It is of larger size and better in flavour and colour than Vicomtesse Héricart de Thury or any other early variety. Amy Robsart has a good deal

Fig. 1.—Laxton's Pioneer.

of the Pine in it, and Dr. Roden informs me that it was raised by crossing Lebreton's Marguerite with the Scarlet Pine, and is an excellent first early forcer. The plant appears to be of good constitution, and although a continuous bearer does not throw so many small fruits as Vicomtesse. I was somewhat unexpectedly surprised at the remarkable pre-eminence exhibited by Amy Robsart as an early variety, it not being heralded here with any flourish of trumpets, that I wrote to Dr. Roden asking if I had the true variety, and he at once sent me the verification. As Dr. Roden does not submit his seedlings to the judgment of the Royal Horticultural Society's Fruit Committee, but waits for public recognition until the merits of his novelties have become patent, it is probable that Amy Robsart is not so well known as it deserves to be. I can unhesitatingly recommend it as a first early variety.

My own Pioneer (first-class certificate Royal Horticultural Society, and sent out by Messrs. Veitch) is the largest and finest of all the early varieties, immediately succeeding Amy Robsart, and I think will be found a great advance on Keens' Seedling. From many quarters I hear it is rapidly gaining in favour both as a garden, market, and forcing Strawberry. I send you a fruit gathered a few days after the first of Amy Robsart, weighing 1 oz. 5 drachms, and exactly 3 inches in diameter. This and all my Strawberries are growing on ground which has not been manured for at least three years, and the whole crop is very promising. Some of the rows dressed with Clay's fertiliser show very decidedly that this preparation is a powerful and permanent stimulant. There is a Strawberry, received from Messrs. Ellwanger & Barry, of Rochester, N.Y., raised by Mr. Durand, also named Pioneer. It has also a great reputation in the United States as an early variety, but it has not yet fruited with me.

The foliage, however, seems distinct from my own variety. About one hundred varieties, including the best of the American and continental varieties, are on trial in the garden.—T. LAXTON, *Bedford*.

KINGSTON AND SURBITON HORTICULTURAL SOCIETY.—JUNE 23RD.

THE sixteenth annual Exhibition of this Society was held on Wednesday in last week at the Recreation Grounds, Surbiton. The Exhibition was a very fair one, and well maintained its position in comparison with former years. Perhaps in a few classes there was a slight falling-off, but the spirited competition in the other classes more than compensated for that. The schedule comprised of seventy-six classes, forty of which were open to nurserymen and professional gardeners, ten to amateurs not employing a gardener, and twenty to cottagers, while ten more were special classes, the prizes being offered by the Members for the county and residents in the neighbourhood.

Store and Greenhouse Plants.—In the class for nine flowering plants Mr. Hinnell, gardener to F. A. Davis, Esq., Anglesea House, Surbiton, exhibited a specially good collection; and in the class for six Mr. Attrill, gardener to J. C. Freake, Esq., Bank Grove, Kingston; Mr. Child, gardener to J. Gray, Esq., Claygate; and Mr. Croxford, gardener to Mrs. Dunnage, Allbury House, Surbiton, were placed in the order of their names, all showing well and evenly matched collections. There were several competitors in the class for a single specimen flowering plant, the prizes being offered by Sir Trevor Lawrence, Bart. Mr. Hinnell taking the first prize for an excellent plant of *Genetyllis tulipifera*; Mr. R. Watson, gardener to T. H. Bryant, Esq., second for a noble example of *Anthurium Schertzerianum*; and Mr. Crafter, gardener to Rev. Mr. Finch, Kingston Hill, third for a well-bloomed *Heath*.

Ornamental-foliage Plants.—Amongst the best of these were some most excellent examples of *Caladiums* exhibited by Messrs. Gregory, Child, and Luff, who were placed first, second, and third respectively for large robust plants some 4 feet through and well coloured, especially the first-prize collection. Large Palms, &c., were staged by Messrs. Crafter and Attrill, who had the premier prizes. Table plants were represented by eight collections, the first prize falling to Mr. Gregory; the second to Mr. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher; and the third prize to Mr. Brand, gardener to W. Clay, Esq., Elm Villa, Kingston, the Hon. Secretary to the Society. All the collections were very good. Several collections of six distinct varieties of *Colens* were exhibited, but with a few exceptions they were only moderately well coloured. The special class for a group of decorative plants, flowering and foliage, arranged on the turf in the space of 100 square feet, brought six collections, all of very high order of merit. The prizes in this class were offered by the President, H. Harrison, Esq.—first prize, four guineas; second prize, three guineas; third prize, two guineas; and fourth prize, one guinea. Mr. Beckett was deservedly awarded the first, Mr. R. Watson the second, Mr. Attrill third, and Mr. Luff the fourth; and the Judges, to mark the superiority of the other collections, awarded extra prizes to the other two competitors, Messrs. Croxford and Buckland. The classes for *Pelargoniums*, *Fuchsias*, *Achimenes*, *Gloxinias*, and *Begonias* were mostly well filled, the whole of which were in high order with the exception of the *Fuchsias*. Several collections of both exotic and British Ferns were staged; Messrs. Hinnell, Crafter, Attrill, and J. Watson being the principal exhibitors.

Cut flowers and table decorations were numerous exhibited, especially the latter. Mrs. Clay was the most successful competitor, obtaining the premier prize in the classes for three stands, single stand, and the best floral cross. A capital collection of twenty-four *Roses* came from Mr. Mace, Teddington, who received the first prize, while Mr. Moorman, gardener to Miss Christy, was placed second, and Mr. Luff third. There were several other collections, but scarcely any of the *Roses* had attained their usual condition. There was not a large display of fruit, but it was of excellent quality. Vegetables were numerous, and seldom have we seen finer contributions from cottagers so early in the season.

The executive had the advantage of a very fine and cheerful day, which induced a large and fashionable company to patronise the Exhibition, and thus enabled the Society to pay all demands and to carry over a balance towards next year's Exhibition.

BULBS AND BEDDING.

As my bulb or spring garden must be turned into a bedding garden with as little delay as possible, and as I do most of the work myself with the help of a young gardener who has his vegetables, Vines, and greenhouse plants also to attend, perhaps my experience may be of use to other lady gardeners in the same predicament. This favourite bedding garden consists of four scrolls, or S's cut in a long belt of grass, with round or pin-cushion beds between. In these round beds (there are twelve of them) are dwarf standard *Roses*, with the centre shoot upright and the side shoots pegged down over the bed. These beds are bordered in spring with *Seillas* and *Crocuses*. The scroll beds

are about 2—4 feet wide and 48 feet long. Two of them I have made the last two winters into what I call bouquet beds, and the effect has been so good that I think in similar beds it might be adopted. I filled them with clumps of Tulips, ten in each clump or cluster, with a space of 18 inches apart. The Tulips in one bed were white (*La Candeur*) and scarlet (*Rex Rubrorum*), and there was a narrow edging of *Golden Feather*. The other bouquet bed was similar, except that it had yellow in it, each third clump being that magnificent double yellow Tulip called *Yellow Rose*. Some people thought the white and scarlet had the best effect, others admired the mixture of gorgeous gold. In each way the effect was pleasing, and the interval of brown earth between each bouquet gave additional brilliancy to the colours. Of the other two beds, one I filled with Tulips of every shade of pink, crimson, and deepest red, using principally (as I happened to have them) *Cardinal*, *Gris de Lin*, *White Swan*, *Rose Gris de Lin*, *Proserpine*, *Purple Crown*, *Roi Cramoisie*, *Rembrandt*, &c. No yellow was allowed to appear in this bed. The fourth was mixed Tulips, every colour, with a good sprinkling of *Chrysolora*. This bed had an edging of *Beet*, the dark crimson purple of which helped to bring out and harmonise with the gay colours of the Tulips.

These beds kept the grass garden a brilliant patch of colour from early in March (I had plenty of *Van Thols* in the greenhouse) until quite the end of May, when my real labour began. I took up each Tulip (the flower stems having been first cut off) with as large a ball of earth as I could take with it, and then moved them all as carefully as possible to some shallow trenches I had made for them in the kitchen garden; there I left them covered over with a sprinkling of earth until a few days ago, when I found that, thanks to the dry sunny weather we have had, the foliage was all withered and the bulbs quite ripe—fine, large, heavy and healthy they are—my sole trouble being that I have too many of them, and shall certainly not have space for more than half of them next year.

As soon as the bulbs were removed the gardener dug the beds over, adding a little fresh soil. As they were well manured before the bulbs are planted there is no necessity for adding any more now; the earth is merely turned up roughly a few days, and then settled for the bedding plants. In one scroll I have *Vesuvius Pelargonium* with *Pyrethrum* border; the next is *Beet* with a border of *Lobelias*. Then comes *Victoria* or *Bouquet Aster*, with border of *Golden Arabis*, and then again *Beet* with *Stachys* border. The beds already look quite furnished, the *Vesuvius* plants being so healthy and full of buds that already the scroll is a brilliant scarlet ribbon. The *Asters*, however, will not be in for some time. By so managing there is really not more than ten days or a fortnight of unsightly bare beds; and as I do the greater part of it myself, with a little weeding boy to carry the bulbs, &c., not liking to take the gardener from more important work, I think it might encourage those who, like myself, have not an army of gardeners under command, to have a spring as well as a summer garden.

I prefer Tulips because they are more easily managed than *Hyacinths*, and, unlike *Hyacinths*, they do not deteriorate but increase and really improve. I have always a few *Hyacinths*, principally those that have done duty in pots the previous year, but they are in another part of the garden, for I think the gayer colours of the Tulips overpower the more tender and delicate hues of their less flaunting cousins.—B.

LEE AND BLACKHEATH HORTICULTURAL SOCIETY.

JUNE 23RD AND 24TH.

THE annual Exhibition of this vigorous and successful Society was held on the above date in its usual position—namely, a large field, the property of Mrs. Penn, The Cedars, Lee. The exhibits were very numerous, occupying two large tents and two of smaller size, the quality being generally much above the average, and the arrangement most tasteful and effective. The competition was keen in most of the principal classes, the result being a highly satisfactory display. The Secretary, Mr. C. Helmer, is deserving of much credit for the efficient manner in which the whole Exhibition was conducted, and we regret that our space will only admit a brief record of the winners in the several classes.

Stove and greenhouse plants were fresh and generally well flowered. Mr. J. Smith, gardener, Eagle House, Eltham, obtaining the chief prize with eight specimens, including a neatly trained *Bougainvillea glabra*. Mr. Jeffery, gardener to J. Young, Esq., Blackheath Park, occupied a similar position with four plants. The collections of twenty-four plants were excellent, Mr. Reeves, Lee; Mr. Beck, gardener to J. H. Young, Esq., Old Road, Lee; Mr. Steward, Blackheath; and Mr. Smith, all exhibiting handsome well-grown specimens.

Pelargoniums formed a fine display in one of the tents. The principal exhibitors were Mr. Martin, Mr. Beck, and Mr. Jeffery, who

gained the chief prizes for twelve, six, and four Show varieties respectively. Other exhibitors in the classes for Zonal, Fancy, and Bronze varieties were Messrs. Reece, Davis, Beacham, Lambert, and Sholdice, who staged very fair examples of well-selected varieties. Gloxinias, Fuchsias, Calceolarias, and Begonias were numerous and good, many of the exhibits already mentioned taking prominent positions.

Ferns were uncommonly healthy, both the exotic and hardy species and varieties. Messrs. Reece, Shrubbs, Bristow, Lambert, and Chappell received the chief awards for neat collections. Fine-foliaged plants were also well represented, classes being devoted to Caladiums, Palms, and Begonias. Messrs. Beck and Lambert exhibited very successfully, Messrs. Bristow, Shrubbs, and Martin also taking substantial honours.

Fruits and vegetables were fairly numerous, and indicated excellent culture. Grapes were especially noteworthy for their good finish, Messrs. Beck, Wright, Buckman, and Bristow staging the best examples and gaining the chief prizes. Mr. Jeffery and Mr. Rainbird were the two of the best exhibitors of vegetables.

In the vegetable and fruit tent Messrs. J. Laing & Co., Forest Hill, had a large and elegant group of plants, including numerous specimens of three fine Tuberous Begonias flowering very freely.

HERBACEOUS PLANTS.

I QUITE agree with "WYLD SAVAGE" in some of his statements on fashion in gardening. Where there is a large place there portions may be kept severely for each style, but I do not any more see why we of the middle class are for ever to be aping those above us. If "my lord" has gone in for ribbon, carpet, and mosaic bedding, there is no valid reason why the parson and the doctor are to follow suit; and if "Sir John" chooses to have an herbaceous garden, and to keep stately plants of that character, that in no way debars me from having half-hardy things in my mixed borders, and to seek for enlivenment in Pelargoniums, Calceolarias, and showy annuals. But I do not understand how, after his enormous outlay, "WYLD SAVAGE" can only enumerate those few plants. Why, I am looking on a clump of *Papaver orientale* you might see half a mile off; then I have a group of *Cypripedium spectabile*, worth all the bedding plants that could fill my garden. Where are his double purple and single Rockets? Has he no Lilies of the *davuricum* and *pomponium* type, no Delphiniums with their stately spikes, no rich floriferous double and single Pyrethrums, no Campanulas or Fraxinellas, no Anthericums or Veronicas? And so I might go on naming a host of plants. "WYLD SAVAGE" complains of not knowing what to buy. I can only say I have seen very reliable lists in the Journal during the present year.

I do not think that up to the end of June a border purely of herbaceous plants ought to be dull. It will not, and never can be, glaring; but bright it may be, and assuredly ought to be, and "WYLD SAVAGE" is to be commiserated if he has had his terraces so dull as not to please "madame." He does not do things by halves, and I am sorry to find that, as with his Roses so with his herbaceous plants, he has to write vanity and vexation of spirit.—VIOLA.

IRISES.—No. 10.

In the same section with and closely allied to the species last described are the two now referred, both of which merit a place among the hardy plant collectors' *protégés*. They are old garden plants, and were known to such writers as Parkinson, Gerarde, Lobel, and others of the sixteenth and seventeenth centuries, and consequently take rank among what may be termed the historical species.

The one represented in the annexed engraving (fig. 2) is *Iris graminea*, the grass-like Fleur de Lis, so named from the character of its foliage, which is long and narrow. The plant is not quite so attractive as many of its relatives, and yet there is a pleasing neatness in the form and coloration of the flowers that render it worthy of consideration. In Miller's "Gardeners' Dictionary" is a clear and lucid description of the species, which was as follows:—"This has narrow, flat, grass-like leaves about a foot long, of a light green colour; between these arise the stalk about 6 inches high, having two narrow leaves much longer than the stalk. Flowers two or three, small; the petals (standards) have a broad yellow line with purple stripes; the three falls are of a light purple colour striped with blue, and have a convex ridge running along them; the others are of a reddish purple variegated with violet; they have a scent like fresh Plums." This description very truthfully represents the plant, except that it does not remark the beautiful veins and streaks on the falls, which constitute the chief attraction of the flower. Gerarde grew the plant in his garden, and published a figure and description of it in the

"Herball," under the name of *Chamaeiris tenuifolia*, and he states that "the floures are in shape and colour like those of the stinking Gladdon but much lesse." It is extensively distributed over the central and southern portions of Europe, and thrives in almost any soil and situation provided it be not too dry.

Iris siberica is a near ally of the above, and like it was well known to the old writers. This is also grown commonly at the present time, few gardens possessing a collection of Irises with any pretensions to completeness being without it or some of its

Fig. 2.—*Iris graminea*.

varieties. The typical form, which is well figured in the first volume of the "Botanical Magazine," is extremely pretty, the flowers being of moderate size, compact, with erect purple narrow standards, and rounded falls of a white ground colour delicately veined with blue. In subsequent volumes of the same work two varieties have been represented, one with white flowers, the other, named *Sanguinea*, a very distinct variety with large rich purplish blue flowers and reddish foliage. It appears in "Parkinson's Paradisus" of 1629 as "*Iris angustifolius major caerulea*, the greater blew flower de luce, with narrow leanes," and bears, as the author says, "diuers flowers successively flowering one after another, and one like unto the flowers of the bulbous flower de luces, but of a light blew colour."

About a dozen named varieties of *Iris siberica* are now in commerce, some departing considerably from the type in their flowers,

but all agreeing in habit. Some of the most attractive are the following:—*Grandiflora*, flowers large, of an intense blue shade; *Lactea*, creamy white; *Pallida*, ground colour pale blue, netted with white; *Altissima*, dark blue, with lighter veins; *Alba*, white with pale purple markings; *Plena*, deep blue, a late-flowering variety. All are equally easy of culture, succeeding under most adverse circumstances even in clayey soil, and, being quite hardy, they may be safely grown in any border without protection. —L. C.

NOTES AND GLEANINGS.

WE learn that the MAIDSTONE ROSE CLUB will hold their Exhibition in the Concert Hall at Maidstone on the 6th inst. In addition to the usual prizes a silver challenge cup, value £12, will be offered for the best box of eighteen Roses. This cup will be retained by the winner of the year, and becomes the property of the exhibitor who gains it three times, not necessarily in succession. A challenge cup valued £5 will also be offered by the Members of the borough for the best ornamental device consisting of Ferns and Roses. The terms relating to the winning of this cup are similar to those of the one previously mentioned, but only the winners of the first and second year can compete in the third. Silver and bronze medals are offered by the National Rose Society, and Mr. B. R. Cant of Colchester contributes three prizes.

— A SALE of peculiar interest to botanists and antiquarians took place last week when the TURRET HOUSE ESTATE, South Lambeth Road, was disposed of by auction for building purposes. Turret House was formerly the residence of the noted John Tradescant, gardener to Queen Elizabeth, whose son served James I. in the same capacity, and his grandson was similarly employed by Charles I. It was on that estate the celebrated collection of plants and curiosities was formed which was subsequently transferred to Elias Ashmole, and is now at Oxford under the name of the Ashmolean Museum.

— WE have received from Messrs. Vilmorin, Andrieux, and Cie., of Quai de la Megisserie, Paris, a number of flowers of their choice strain of CARNATIONS. They embrace almost every conceivable shade of colour, and are very beautiful, being perfectly double and of a hardy constitution. This strain of Messrs. Vilmorin's house enjoys a very extended and old reputation, and we believe may be obtained through any seedsman in this country in the original sealed packets direct from Paris.

— WE recently observed in Messrs. Backhouse's nursery at York an uncommonly fine display of *ODONTOGLOSSUM VEXILLARIUM* with flowers of extraordinary size. Several handsome varieties were represented, the most remarkable being *picturatum*, *giganteum*, and *floribundum*, some of the flowers were $5\frac{1}{2}$ inches long by 4 in width, of beautiful form and great substance. One spike had no less than a dozen similarly large flowers, and the effect produced by a fine bank of plants all flowering profusely was most attractive. This beautiful Orchid is now frequently seen in grand condition at the chief horticultural exhibitions, but rarely are such fine examples staged as those referred to above.

— MESSRS. J. CARTER & Co., High Holborn, have now on view in the Royal Botanic Society's Gardens their usual fine EXHIBITION OF ANNUALS, which are in excellent condition, a very large number of species and varieties being represented. These attractive plants are now attracting some of the attention they deserve, and the above collection affords a good opportunity to intending growers of making a selection of the most ornamental.

— IN a communication we have received from Tweedside in the district where the extremely LOW TEMPERATURE of 17° below zero was recorded last winter, our correspondent writes—"I have not an Apple or Pear on my ninety trees in the orchard, and on the walls only one, two, or three. Many of the old Apple and

Pear trees have died in the orchard here; and close to Swinton House I saw rows of old Oaks probably one hundred years old without any appearance of vegetation. It has been a dreadful winter, but at Hope Park with the exception of one Peach tree and one Apple tree I have escaped with a little scorching. There is no fruit anywhere."

— MESSRS. HOOPER & Co. of Covent Garden inform us that they have obtained several hundred plants of *SELAGINELLA LEPIDOPHYLLA*, which is termed the "Resurrection Plant," and is well known to possess peculiar hygrometric properties, similar to the Rose of Jericho. The old dry plants have all their fronds rolled inwards so as to form a brown ball-like object. When placed in water the fronds speedily commence unrolling, and in the course of several hours they are unfolded, the inner surface being green, and the specimen thus appears to be a living plant. The one submitted to our inspection was immersed in water for more than twenty-four hours before it was fully expanded, and when removed from the water about the same time was occupied in returning to its former condition. It is, however, not only a curiosity, but like other species of similar rosulate habit, living plants form pretty little tufts of dark green fronds, and may be grown in pots in an ordinary fernery.

— THE handsome variegated Coral Tree, *ERYTHRINA MARMORATA*, was exhibited by Messrs. J. Veitch & Sons at South Kensington on Thursday week in excellent condition, when a first-class certificate was awarded for it. The leaves are large, green, finely marbled with white, and render the plant very distinct and valuable for decoration.

— J. MCINTOSH, Esq., Dunevan, Oatlands Park, Weybridge (gardener, Mr. Taylor), exhibited at the last meeting of the Royal Horticultural Society, as recorded in our report, a plant of *LILIUM POLYPHYLLUM*, an extremely rare species, and has flowered very few times in this country. The flowers were large, of a greenish white colour, the inner part of the perianth being spotted and streaked with purple. It is not one of the most beautiful Lilies, but is interesting for its rarity. It is found in the Himalayas.

— IN the House of Commons the IRISH POTATO DISEASE Committee is now engaged in investigating the causes of and possible remedies for the destructive fungus *Peronospora infestans*, the ravages of which are so severely felt in Ireland and elsewhere. Although a definite solution of the difficulty cannot be expected, yet we may confidently look for some advance in that direction if the matter is carefully and thoroughly examined.

— WE have had upon our table for the past month an umbel of *ALLIUM MOLY*, which has only just expanded the last of its flowers. It has not been placed in water once during the whole of that time, and yet the flowers have continued expanding, apparently deriving the necessary support from the substance of the peduncle, which is very fleshy.

— AN extremely handsome member of the Iris order is now flowering in the herbaceous ground at Kew—namely, *XIPHION TINGITANUM*, one of the beautiful bulbous section, of recent introduction. It has narrow leaves and large imposing flowers of a rich purplish blue colour, with rounded falls of great size.

— DR. R. BRAITHWAITE is now publishing his monographs of the different families of Mosses, under the title of "THE MOSS FLORA." The work is well illustrated by plates of all the species, and microscopical analyses of their parts.

— WE learn that with the view of forming a PARK FOR CROYDON the Board of Health have purchased 7 acres of land, which is about to be laid out in an ornamental manner. The total cost is estimated at £14,000.

— AMONG the numerous beautiful Larkspurs two of the

finest are DELPHINIUMS BRUNONIANUM and BELLADONNA. They both have large and well-formed flowers, the former being of a rich bright clear blue, and the latter of an exquisite light blue tint that can scarcely be rivalled.

— A DAILY contemporary states that Dr. C. W. Siemens has found an economic use for the ELECTRIC LIGHT in the cultivation of fruits and flowers, and he is now about to put down a steam engine at his country residence, which will at once supply the hot water to warm them, and the light to bring them to a speedy maturity. The engine will, at the same time, be employed to cut wood and chaff, to mince food for the cattle, and to do much of the other work of the farm, and then, by charging the engine with the remainder of the expense for furnishing light at night, Dr. Siemens expects to be able to prove that electricity may be used with advantage in growing fruit, flowers, and vegetables.

— A CORRESPONDENT referring to the FLOWERS IN VICTORIA PARK observes, that "Gay as is the long herbaceous border there at the present time, yet where it had one admirer last Sunday night the carpet beds so artistically designed and tastefully planted had at the least a hundred; it were therefore equally reasonable for any 'one-idea' man to denounce this form of garden decoration as for an Irishman to quarrel with his English neighbours for considering there is other food fit to eat besides Potatoes."

— WE have received from Messrs. W. E. Brown & Sons, the Nurseries, Wells, Somerset, a DOUBLE SEEDLING PETUNIA which they have raised this season. It is of unusual size, measuring 8 inches over. It is rich purple in colour, the central petals being contorted, forming a loose ball. It is a remarkable flower, but more curious than beautiful.

— A PARTICULARLY beautiful border plant at this time of year is LYCHNIS FLOS-JOVIS, and when thriving, as it will in almost any ordinary garden soil, it bears large, very bright rosy pink flowers in great profusion. The plant is moderately compact in habit, with woolly leaves, and forms a remarkable contrast to the brilliant Lychnis chalcedonica.

— M. ERNST of Caracas has recently published some interesting observations upon the fertilisation of COBÆA PENDULIFLORA, which confirm the opinion expressed by Sir Joseph Hooker in the description accompanying the figure of the plant in the "Botanic Magazine" ten or twelve years ago—namely, that the flowers seemed structurally adapted to ensure cross-fertilisation. The corollas have narrow greenish petals 4 or 5 inches in length, the stamens having similarly long filaments, which are at first curiously twisted, but are ultimately bent outwards from the centre of the flower, thus removing the anthers to a considerable distance from the stigma. The anthers have been found by M. Ernst to burst and liberate the pollen early in the evening, after which nectar is copiously secreted around the base of the ovary. The fertilisation is effected by several species of nocturnal moths, which visit the flowers and convey the pollen on their wings. There appears to be an inherent unfitness for self-fertilisation, as the experiments made by M. Ernst to accomplish this proved ineffectual. Living plants of Cobæa penduliflora were sent to Kew by this gentleman, and one flowered in the Palm house in 1868.

HELLEBORE POWDER VERSUS CATERPILLARS.

HAVING noticed in the Journal, on pages 317 and 454 of the last volume, directions for destroying the Gooseberry caterpillar, and being much troubled with the pest, which appears to be almost divesting our bushes of their foliage, I resolved to give the directions a trial. As I have a large number of bushes, also trees trained to walls 9 feet high, and not being possessed with great patience, I adopted a somewhat different mode of applying the hellebore powder. In the one case I employed a garden syringe in place of a whitewash brush, and in the other a cheesecloth

(straining) instead of muslin. I have much pleasure in stating the result of the first dressing is most satisfactory—thousands of caterpillars lie dead under the bushes.

Allow me to ask if the fruit will be injured by the hellebore. I saw a thief busy to-day, and although I should be glad to know she was punished, I should be sorry to see her under the bushes with the caterpillars.—R. R. GODFREY, *Grantham*.

P.S.—I have bees in my garden, and they are often upon the Gooseberry bushes; will hellebore have the same effect upon them as upon the caterpillars?

ROYAL HORTICULTURAL SOCIETY.

JUNE 29TH.

THE Rose Show of the Society and the Exhibition of the Pelargonium Society were as last year held in conjunction, and fortunately under the most favourable conditions as regards the weather. The exhibits, too, were numerous for the miscellaneous collections. Roses, Pelargoniums, and vegetables entirely filled a tent 500 feet in length. A few plants were staged in the Council-room, but one of the most pleasing and artistic features of the Show were the groups from Mr. H. Cannell of Swanley, which were arranged in the vestibule. The plants were arranged on two long parallel tables leading from the entrance to the Council-room, the back row being formed of dark blue Delphiniums, the centre of Tuberous Begonias, and the front margin of *Herniaria glabra*, in which were dotted plants of the variegated *Polemonium caeruleum* and *Lobelias* alternately. Baskets of Pansies, Sweet Williams, and extremely fine Verbenas were also arranged at the ends, the general effect being most satisfactory. A gold medal was deservedly awarded for these artistic groups.

ROSE SHOW.

A large number of collections were staged in the eleven classes devoted to cut Roses, and the majority were distinguished by more than usual excellence. A charming freshness was generally evident in the blooms, the colours bright and clear, and many exceptionally handsome blooms were included in some of the collections. In the nurserymen's class for forty-eight single trusses there were five entries, the chief prize going to the Cranston Nursery and Seed Company, King's Acre, Hereford, for a collection of extremely fresh and even blooms. The most noticeable were Général Jacqueminot, grand; John Stuart Mill, fine; La France, good; and Marie Baumann, fine. Messrs. Curtis, Sanford & Co., Torquay, were second with a good collection, but not quite so neat. Mr. F. Cant, Colchester, was a good third with twenty-four triplets. Messrs. Cranston were again first, staging a very handsome collection. The following were the varieties:—Etienne Levet, Madame La Baronne de Rothschild, Exposition de Brie, La France, Le Havre, Madame Lacharme, La Rosière, Mons. Noman, Hippolyte Jamain, Mons. E. Y. Teas, Marquise de Castellane, Fisher Holmes, Madame Chas. Wood, Marguerite de St. Amand, Mdlle. Marie Cointet, Prince Camille de Rohan, Mons. G. Tournier, Madame Noman, Général Jacqueminot, Madame Marie Finger, Miss Hassard, Princess Beatrice, and Maurice Bernardin. Messrs. Curtis, Sanford & Co. were second, and Messrs. Keynes & Co., Salisbury, third, both exhibiting collections nearly equal in merit. Messrs. Cranston, Curtis, and Kimmont & Kidd, Canterbury, were first, second, and third respectively with twenty-four single trusses, all fresh and bright. Messrs. Cranston had a very fine premier collection of twelve single trusses. Messrs. Kimmont and Kidd and Keynes & Co. following with fair blooms, but rather weak in one or two points.

The amateurs showed remarkably well. In the principal class for twenty-four trusses there were five entries. R. N. G. Baker, Esq., Heavitree, Devon, obtained the chief honours with a handsome collection, including grand examples of Auguste Rigotard, La France, Duchesse de Caylus, Mdlle. Marie Rady, and Mons. E. Y. Teas. T. Jowitt, Esq., Old Weir, Hereford, was an excellent second, his Alfred Colomb being admirable. A. J. Waterlow, Esq., Great Doods, Reigate (gardener, Mr. Browne), followed with neat specimens. Out of seven exhibitors of twelve triplets Mr. Baker staged the finest and freshest blooms; Marie Baumann was very handsome, Auguste Rigotard neat, Charles Lefebvre fine, Docteur André fine, and Mons. Etienne Levet in excellent form. T. Jowitt, Esq., was second, Exposition de Brie, Mons. E. Y. Teas, and Mdlle. Marie Cointet being well represented. G. P. Hawtry, Esq., Aldin House, Slough, was third with creditable blooms. J. B. Haywood, Esq., Reigate (gardener, J. Ridout), Mr. Jowitt, and the Rev. E. J. Fellowes, Wimpole Rectory, Royston, were first, second, and third with twelve single trusses, and extra prizes were awarded to J. H. Pemberton, Esq., The Round House, Havering-atte-Bower, and Mr. Baker. In the class for twelve Tea or Noisette Roses Mr. Fellowes obtained the chief prize with a neat collection; C. Davies, Esq., The Grammar School, Banbury, and Messrs. Cranston being second and third, Mr. Hawtry securing an extra prize. The six exhibitors in this class all staged fair examples of some of the best varieties in cultivation. The principal prizetakers in the classes for six Hybrid Perpetuals and six Teas or

Noisettes were Messrs. Baker, Curtis, Cranston, and J. Davis, Esq., The Square, Wilton.

In the class for six new varieties of Roses of 1877-8 Messrs. Cranston obtained the chief award with Gaston Levêque, a large finely formed Rose of a rich crimson hue; Leon Renault, good form, very bright red, full; Madame Gabriel Luizet, light crimson, neat; Souvenir d'A. Thiers and Constantin Fretiakoff, somewhat alike in form and of a deep rosy crimson; and Marchioness of Exeter. Mr. G. W. Piper, Uckfield, was second with Mdle. Marie Verdier, Souvenir de Madame Robert, John Fraser, Barthelemy Joubert, and Oxonian. Messrs. Curtis & Co. were third with Penelope Mayo, Boieldieu, Cannes la Coquette, Mdle. Marie Verdier, Marie Louise Pernet, and Barthelemy Joubert.

MISCELLANEOUS EXHIBITS.—Several groups and collections were staged which attracted much attention. Among these the herbaceous plants from Messrs. Barr & Sugden were especially noteworthy, a silver-gilt medal being awarded. Mr. H. Hooper, Bath, obtained a silver Banksian medal for a collection of Pansies and Carnations. Messrs. Pearson of Chilwell contributed a fine group of Pelargoniums, for which a silver Banksian medal was awarded. Mr. Aldous, South Kensington, obtained a bronze Flora medal for a group of plants; Messrs. Carter & Co. a silver Flora medal for a large group of annuals; and Messrs. F. & A. Smith for a collection of Pelargoniums. A group of Pelargoniums from the Society's garden was also staged, and in the Council-room were some new plants from Mr. Bull, Chelsea. In the grounds Messrs. Foster & Pearson again exhibited examples of their frames.

The only exhibitor in the class for nine Tuberous Begonias, in which the prizes were offered by Messrs. Laing & Co., Forest Hill, was J. S. Law, Esq., South Lodge, Southgate (gardener, Mr. Tong), who was awarded the first prize.

SPECIAL PRIZES FOR VEGETABLES.

A fine lot of vegetables were staged in these classes, the competition with one exception being very keen. For the prizes offered by the Messrs. James Carter & Co. for fifty pods each of Carters' Straggon, Culverwell's Telegraph, and Carters' Telephone Peas brought together five collections of these exceptionally fine varieties. The first prize was well won by Mr. J. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, Taibach, South Wales, with magnificent pods, large and well filled; the second prize was awarded to Mr. J. Richardson, Boston, Lincolnshire; the third prize to Mr. G. T. Miles, gardener to Lord Carington, Wycombe Abbey, Bucks; the fourth to Mr. R. Phillips, gardener to Capt. Jackson, The Deodars, Meopham, Kent; and the fifth to Mr. W. Iggulden, gardener to Capt. D. Wingfield, Orsett Hall, Romford, the exhibits in each instance being of great merit.

Nine exhibitors responded to the offer of prizes by the Messrs. Sutton & Sons, Reading, for twelve dishes of vegetables, the competition being very close indeed. The kinds were stipulated, but the varieties were left to the option of the exhibitors. Mr. G. Miles secured the premier award with excellent Nantes Horn Carrots, Early White Naples Onions, Canadian Wonder Beans, Seville Longpod Broad Beans, Culverwell's Telegraph Peas, Tender and True Cucumbers, Walcheren Cauliflowers, Wilmot's White Cos Lettuce, and good dishes of Munich Turnips, Pine Apple Beet, Victoria Cabbage Lettuce, and Improved Lapstone Kidney Potatoes. Several of the collections staged for the remaining prizes followed very closely on the premier collection, the Judges experiencing considerable difficulty in awarding the prizes, and as a matter of course did not entirely please all the competitors. The second prize was awarded to Mr. G. W. Meads, gardener to Viscount Barrington, Beckett Park, Shrivenham, who staged among others good dishes of Nantes Horn Carrots, Improved Lapstone Potatoes, Italian Tripoli Onions, Leviathan Broad Beans, and Duke of Connaught Cucumbers. Mr. Haines, gardener to the Earl of Radnor, Coleshill House, Berks, followed, his collection including good Seville Longpod Beans, Nantes Horn Carrots, and Suttons' Improved Telegraph Cucumbers. The remaining prizes were awarded to Mr. J. Muir, Mr. W. Iggulden, and Mr. J. Austen, gardener to Sir G. Smythe, Ashton Court, Bristol, in the order named. The latter exhibitor staged a wonderfully fine dish of Giant Rocca Onions.

Messrs. Webb & Sons' (Wordsley, Stourbridge) prizes were offered too early in the season, which accounts for there being two competitors only. The prizes were for six kinds of vegetables, which include Webb's Triumph Pea (a main crop variety), and Webb's Banbury Onion. In addition to the stipulated varieties Mr. Iggulden staged good dishes of Woodstock Kidney Potato, Early London Cauliflower, Trophy Tomatoes, and Nantes Horn Carrots, and was awarded the first prize. Mr. W. Crump, gardener to the Duke of Marlborough, Blenheim, secured second honours with creditable dishes of Hathaway's Excelsior Tomatoes, Webb's Perpetual Bearer, International Kidney, and Early London Cauliflower, in addition to the stipulated varieties.

The prizes offered by Messrs. Webber & Co., fruiterers, Covent Garden, for the best packed boxes of fruit, to consist of one box of Grapes, one of Peaches, and one of Strawberries, were obtained by Mr. W. Crump, gardener to the Duke of Marlborough, Blenheim Palace, Woodstock, and Mr. J. Wallis, gardener to the Rev. Walter Sneyd, Keele Hall, Newcastle, Staffordshire, in the order named, both with very careful examples of packing, the fruit having arrived in excellent condition.

THE PELARGONIUM SOCIETY'S SHOW.

The display of Pelargoniums was extremely good, all sections being well represented. Show, Fancy, and Zonal varieties were staged in considerable numbers, the competition in several of the classes being close. The new varieties were also especially fine, many of exceptional merit being exhibited. The schedule enumerated twenty-three classes, the first eight being devoted to new varieties not yet in commerce, and each class was in three divisions, a single prize being offered in each. From nine to nineteen were appropriated to specimens, and the remaining four classes to cut blooms.

The following were the chief exhibits in the classes for new Pelargoniums:—*Show Varieties.*—No prize was awarded in Class 1. In Class 2A, for three distinct Show varieties, Mr. C. Turner, The Royal Nurseries, Slough, was awarded the first prize. His varieties were Hector (Foster), symmetrical flower, bright salmon lower petals, very dark upper, with a lighter margin, and clear white eye; Maid of Perth (Foster), very fine flowers, rosy lower petals, distinct white centre, and very dark upper with narrow margin; Mountain of Light (Foster), flowers of moderate size, bright scarlet, and dark blotch in upper petals. In Division B, for two specimens, Henry Little, Esq., Hillington Place (gardener, Mr. G. Wiggan), was first with Ruth Little and Formosa, both of Jackson's raising; the former of a clear rosy colour, and the latter with creamy lower petals, the upper petals in each being very dark. In Division C, for one variety, the Rev. A. Matthews, Gumley, Market Harborough, was first with Sir W. Scott (Matthews), a fine flower with intensely dark upper petals and salmon scarlet lower petals, the flower being of good form. In Class 4A, for three, including market and regal varieties, Messrs. J. & J. Hayes, Edmonton, were first with Mr. John Hayes, Mrs. John Hayes, and Lady Isabel, all very floriferous varieties, and of good habit. In Division B Mr. Little was first with Bridesmaid and Rosy Morn, both of Jackson's raising; the former very attractive, with fine trusses of flowers; the lower petals white, and the upper veined and marked with crimson. In Division C Mr. C. Turner gained the first prize with Macbeth (Foster), a very distinct variety, flowers of great size, salmon hue, petals blotched in the centre, and very dark upper petals. Mr. Turner was the only prizetaker with three new Fancy Pelargoniums—viz., Queen of the Hellenes, Jenny Howlett, Lady Hardy, all very neat and distinct. *Zonal Varieties.*—In Class 5, Division A, Dr. Denny was first with Lalla Rooke, fine scarlet, immense trusses; Prima Donna, an exceptionally handsome white; Cynthia, fine magenta, neat flower and truss, habit dwarf. In Class 6A, for double varieties, Messrs. Saltmarsh & Sons, Chelmsford, won with Mrs. Arthur Lattey, fine pink, large truss; and Lord Cecil, handsome scarlet. In Division B Mr. Turner had a neat variety, named Kensington, with white flowers and yellow foliage; and one named Nancy Lee, with scarlet flowers and variegated foliage. Mr. H. Cannell staged the only new Ivyleaf variety, one of Sisley's raising, named Beauté de Lyon. The flowers were large, of good form, and somewhat of a scarlet tinge.

In the classes for specimens the exhibits were numerous. With six Show varieties Mr. Little was first, staging very symmetrical plants. Mr. C. Turner was second with smaller specimens, but bearing handsome flowers; Victory was especially noteworthy for the size and colour of the blooms. Mr. F. Hunt, York Lodge, Stamford Hill, was third with well-grown plants, but bearing few flowers. Mr. Turner was first with eighteen Show varieties, his collection included a good selection. Mr. Little and Mr. W. Meadmore, Romford, followed with fair specimens. Mr. Little staged the best collection of nine decorative varieties, the specimens being exceptionally fine, Kingston Beauty and Duchess of Edinburgh flowering grandly. Mr. C. Turner followed with plants bearing fine trusses but somewhat uneven. Third, Messrs. J. & J. Hayes with good plants. The prizes for eighteen Show varieties were obtained by Messrs. J. & J. Hayes and Mr. H. Little. Among the Fancy varieties Mr. C. Turner obtained the chief position with six plants remarkably well flowered. The Jewess, The Shah, and Princess Teck were fine. Mr. H. Little took the second position with handsome specimens; and Mr. Hodgson, The Elms, Hampstead (gardener, Mr. J. Weir), was third.

The Zonals were very fine. In the class for nine Mrs. Lermite, Finchley (gardener, Mr. J. Catlin), obtained the premier position with good specimens over 4 feet in diameter, and bearing numerous trusses of flowers; Fanny Catlin, Lizzie Brooks, Mrs. Pearson, and Ellen were very handsome. D. Martineau, Esq., Clapham Park (gardener, Mr. J. Weston), was second with inferior plants, and Mr. W. Meadmore third. Mr. Catlin, Mr. Little, and Mr. Meadmore received the prizes in the class for eighteen specimens. In the class for nine double-flowered Zonals Mrs. Lermite was awarded the premier prize for symmetrical well-flowered specimens. G. Simpson, Esq., Wray Park, Reigate (gardener, Mr. J. King), and Mr. W. Meadmore being second and third respectively. Mrs. Lermite was first with eighteen double Zonals; Mr. J. Balaam, Vine Nursery, Lower Clapton, second; and Mr. W. Meadmore third.

The cut blooms were remarkably fresh and good, some of the trusses being of enormous size and the colours brilliant. Show varieties were well shown by Messrs. Turner, Saltmarsh, and Meadmore, who gained the chief prizes. Zonals were grandly exhibited by Mr. H. Cannell, his collections attracting great attention; and other prize-winners in that class were Messrs. Saltmarsh, Meadmore, Mr. G. Duffield, gardener to H. K. Mayor, Esq., Winchmore Hill, and Mr. J. Dixon, Christchurch Lodge, Hampstead. Double-flowered varieties were well shown by Dr. Denny and Messrs. Saltmarsh; the only

collection of Ivy-leaved varieties being from Mr. George, gardener to Miss Nicholson, Putney Heath.

Certificates were awarded for the following varieties—To Dr. Denny for a double Zonal variety named *Enchantress* (Denny), with large trusses of pink flowers and of good habit; for the single Zonal *Ulysses* (Denny), a handsome variety with symmetrical blooms in compact trusses, of a brilliant scarlet colour; *Progress* (Denny), a double Zonal of a rich scarlet shade, very neat flowers and good habit; *Prima Donna* (Denny), a handsome white Zonal variety, with flowers of excellent form and great substance. To E. R. Foster, Esq., Clewer Manor, for a Show variety named *Constitution* (Foster), with blooms of the most exact symmetry; the lower petals of a pale salmon pink hue, a white centre, and intensely dark maroon upper petals with a

narrow margin; *Minotaur* (Foster), somewhat resembling the above, but with darker lower petals. To Henry Little, Esq., for an attractive decorative variety, *Bridesmaid* (Jackson). It was extremely floriferous, the blooms being slightly crimped; the lower petals white, and the upper light crimson; truss large, and habit compact. *Hayes' Seedling* (Hayes), a decorative variety, with very large flowers of a bright soft pink colour relieved by a small blotch in each petal. *Criterion* (Jackson), very free in habit; flowers of good form, colour rich scarlet. To Mr. W. Brown, Hendon, for a decorative Pelargonium *Eclipse* (Brown), truss very compact; flowers of a pale cerise or pinkish tinge blotched with a deep tint. To Messrs. J. & J. Hayes for a decorative variety *Mrs. Ashby* (Hayes), very attractive; upper petals extremely dark; lower pink, clear white centre. To Messrs. Salt-

Fig. 3.—MR. J. DOMINY.

marsh & Sons for the double Zonal *Lord Cecil* (Saltmarsh), a grand variety with enormous trusses of brilliant scarlet flowers.

MR. JOHN DOMINY.

AFTER a term of forty-three years in the service of one firm Mr. Dominy seeks the repose that he so well merits. The event of his retirement from an active and singularly successful term of labour is appropriate for presenting to our readers a portrait of this skilful and indefatigable worker in the cause of horticulture. To hundreds of our readers the features will be familiar, and thousands more in this and other lands will be glad to see a portrait engraving of one whose name is a household word to them, but with whom they have necessarily not been brought in contact.

The following brief biographical notice of Mr. Dominy will not be without interest at the present time. He was born at Gittisham in 1816, and in due time was apprenticed to Mr. Guscott, gardener to the Misses Putt, Pomeroy House, Gittisham, Devon. At eighteen

years of age—namely in 1834, he went to Messrs. Lucombe, Pince, and Co.'s nursery at Exeter, and remained there three months; from thence he removed to Messrs. Veitch's nursery in the same town, and remained there until June, 1841. He then went as head gardener to J. Pellagor, Esq., Redruth, and remained in that capacity four and a half years. During that time he took between seventy and eighty prizes for fruit, vegetables, and flowers. He returned to Messrs. Veitch's, Exeter Nursery, working in conjunction with the late Mr. James Veitch until his removal to London, and he remained at Exeter with Mr. James Veitch, senr., twelve years. During his stay at the Exeter Nursery he commenced his first attempts at the hybridisation of *Nepenthes* and *Orchids*, the results of which have now become so widely known. In 1864 he removed to London to take charge of the Royal Exotic Nursery, Chelsea, and from this great firm, which he has served so faithfully and so well, he proposes to retire during the ensuing month.

On Mr. Dominy leaving Exeter he was presented with a silver tankard and cream jug, value £20, by the Devon and Exeter Horticultural Association, "in acknowledgment of his valuable

services to the Society during his connection with Messrs. Veitch," who also presented him with a cream jug to match "in commemoration of his having been the first successful hybridiser of *Nepenthes* and *Orchids* in Europe." He also holds the large silver medal of the above Society "for his perseverance and success in raising the first hybrid *Orchid*," this medal being dated 1858, and refers to *Calanthe Dominii*, the result of a cross between *C. masuca* and *C. furcata*. But it will be well to present in tabulated form the results achieved by this assiduous worker which we have obtained from him; the names to which asterisks are attached indicate the plants raised, those above and below being the parents:—

<i>Calanthe masuca</i>	<i>Goodyera discolor</i>
* <i>Calanthe Dominii</i>	* <i>Goodyera Veitchii</i>
<i>Calanthe furcata</i>	<i>Anæctobilus Veitchii</i>
<i>Phajus rand folius</i>	<i>Nepenthes distillatoria</i>
* <i>Phajus irroratus</i>	* <i>Nepenthes hybrida</i>
<i>Calanthe vestita</i>	<i>Nepenthes</i> , spotted species from Borneo, unnamed
<i>Cattleya guttata</i>	<i>Cattleya (Lælia) crispa</i>
* <i>Cattleya hybrida maculata</i>	* <i>Cattleya Devoniensis</i>
<i>Cattleya intermedia</i>	<i>Cattleya guttata</i>
<i>Limatodes rosea</i>	<i>Cattleya granulosa</i>
* <i>Calanthe Veitchii</i>	* <i>Cattleya hybrida</i>
<i>Calanthe vestita</i>	<i>Cattleya Harrisoniæ</i>
<i>Cattleya Loddigesii</i>	<i>Nepenthes distillatoria</i>
* <i>Cattleya Brabantia</i>	* <i>Nepenthes hybrida maculata</i>
<i>Cattleya Aclandiae</i>	<i>Nepenthes</i> , spotted species from Borneo, unnamed
<i>Cypripedium barbatum</i>	<i>Cattleya maxima</i>
* <i>Cypripedium vexillarium</i>	* <i>Cattleya Dominiana</i>
<i>Cypripedium Fairrieanum</i>	<i>Cattleya amethystina</i>
<i>Cypripedium Pearcei</i>	<i>Nepenthes Rafflesiana</i>
* <i>Cypripedium Dominii</i>	* <i>Nepenthes Dominii</i>
<i>Cypripedium caudatum</i>	<i>Nepenthes</i> , green species from Borneo, unnamed
<i>Cattleya Mossiæ</i>	<i>Cattleya Mossiæ</i> (Syn House vars.)
* <i>Cattleya Manglesi</i>	* <i>Cattleya exoniensis</i>
<i>Cattleya Loddigesii</i>	<i>Lælia purpurata</i>
<i>Cypripedium barbatum</i>	<i>Cattleya (Lælia) crispa</i>
* <i>Cypripedium Harrisianum</i>	* <i>Cattleya Sidniana</i>
<i>Cypripedium villosum</i>	<i>Cattleya granulosa</i>
<i>Cattleya Aclandiae</i>	<i>Aërides affine</i>
* <i>Cattleya quinquecolor</i>	* <i>Aërides hybridum</i>
<i>Cattleya Forbesii</i>	<i>Aërides Fieldingi</i>
<i>Cattleya (Lælia) crispa</i>	<i>Dendrobium nobile</i>
* <i>Cattleya (Lælia) Pilcheri alba</i>	* <i>Dendrobium Dominii</i>
<i>Cattleya (Lælia) Perrinii</i>	<i>Dendrobium moniliforme</i>
<i>Cattleya (Lælia) crispa</i>	<i>Cattleya labiata</i>
* <i>Cattleya (Lælia) Pilcheri</i>	* <i>Lælia Veitchiana</i>
<i>Cattleya (Lælia) Perrinii</i>	<i>Cattleya (Lælia) crispa</i>
<i>Cattleya maxima</i>	<i>Cattleya crispa</i>
* <i>Cattleya Dominii alba</i>	* <i>Cattleya (Lælia) Felix</i>
<i>Cattleya amethystina</i>	<i>Cattleya Regnelli</i>
<i>Goodyera discolor</i>	<i>Cattleya Dowiana</i>
* <i>Anæctobilus Dominii</i>	* <i>Cattleya Dominiana</i>
<i>Anæctobilus xanthophyllus</i>	<i>Cattleya Exoniensis</i>
<i>Fuchsia serratifolia</i>	
* <i>Fuchsia Dominii</i>	
<i>Fuchsia spectabilis</i>	

Such a record needs no comment, and it fully justifies us in bestowing a meed of honour on a man who has proved by his works that he so well deserves it. He has set a worthy example, and we know there are many others working earnestly in the same cause and who will win public approval of their services.

Many will join us in the hope that Mr. Dominii will live long in the esteem of a host of friends and enjoy the rest to which he is so justly entitled.

ANTWERP ROSE SHOW.

THE schedule of the Antwerp rosarians has been kindly sent to me by the President, M. Lenaerts, a gentleman now known, at least by name, to most members of the National Rose Society. The following abstract of the schedule may be of interest to your readers. In the first section (amateur members) there are ten classes: the first six are for cut Roses of any sort consisting of ten, fifteen, twenty, thirty, fifty and one hundred varieties. The prizes are silver and bronze medals in each class. Class 7 is for fifteen Teas, Noisettes, and Hybrid Teas; Class 8 for twenty-five "Roses de premier choix"; Class 9 for pot Roses in flower (no number specified); Class 10 is for lady amateurs, and consists of a collection of Roses not exceeding fifty. Classes 7 to 10 have three medals.

In the second section (nurserymen members) there are twelve

classes. The first seven consist of collections of fifteen, twenty, twenty-five, fifty, seventy-five, and one hundred of any sort, and twenty Teas, &c. The eighth class is for "the most remarkable and the most numerous collection." Classes 9 and 12 are similar to Classes 8 and 10 in the amateurs' section. Classes 10 and 11 are for pot Roses, Class 11 being special for Roses grown on franc-de-pied and greffé rez terre stock. The prizes throughout are medals. The third section is open, and consists of three classes. Class 1 is for the most beautiful collection of the newest Roses; Class 2 is for fifteen Roses remarkable for perfume; Class 3 for twenty-five of special merit in form and colour. It is to this last class that the National Rose Society medals have been allotted.

The Hon. President offers a gold medal to the exhibitor who shall have by the number and beauty of his exhibits contributed most efficiently to the general attractiveness of the Exhibition; then follow medals for bouquets, ball, wedding, table, hand, &c., and a medal for a work dealing practically with the cultivation of the Rose.

As this Rose Show is to be held (August 22nd to 24th) at the same time as the fêtes in connection with the fiftieth anniversary of Belgian Independence, travellers, if rosarians, will perhaps like to make a note of it in their pocket-books. Antwerp itself is thoroughly well worth seeing, and the Rose Show there will by its novelty in effect and arrangement prove an additional item of interest.

I shall be happy to send this schedule to anyone who might think of competing and would like to examine the necessary conditions for doing so.—J. M. FULLER.

REIGATE ROSE SHOW.

REIGATE this year commences the season certainly a week too soon, though that might have been overcome but for the torrents of rain. Most acceptable in other ways, rain in June does not suit on the eve of a Rose Show. The result was a small Show, and Roses hardly up to the standard. The Show was held, by permission of Lady Henry Somerset, in the beautiful grounds of The Priory, which the public were permitted freely to traverse, while a band during the afternoon further enlivened the proceedings. The Judges were the Rev. H. H. D'Ombraim and Messrs. G. Paul and Francis. A box of new Roses was exhibited by the Messrs. Mitchell, who also attended, while Mr. Ivory of Dorking contributed further to the tents' adorning.

For the twenty-fours only three boxes were entered. The prize-takers were in order Messrs. Waterlow, Haywood, and Sargent. The principal contest was, as usual, amongst the twelves and for the ladies' challenge cup, taken yearly by the best box of twelve in the room. Collections of nine were shown by Messrs. Haywood, Cheales, and Sargent, who were first, second, and third respectively; an extra being awarded to Mr. Hawtry. For six of any kind Messrs. F. Pawle and E. Chambers were first and second. For twelve Teas Mr. Waterlow was first, and Messrs. Cheales and Hawtry equal second. Messrs. F. Pawle and E. Horne were first and second with six Teas.

In this Association the National Rose Society's medals are given for the best H.P. and best Tea. The former was taken by Mons. E. Y. Teas (Mr. Haywood), the latter by Madame Bravy (Mr. Cheales). For twelve of any kind Messrs. Haywood and Waterton took the two prizes with Marie Baumann and Marquise de Castellane respectively. Table decorations were shown by Miss West, Miss T. Thornton, and Mrs. F. Guimareaus, who received the prizes in the order named; hand bouquets by Mrs. C. D. Harding and Lady Henry Somerset; and button-hole bouquets by Miss Cheales and Miss Horne, one from Miss Edith Cheales being highly commended.

After concluding their labours the Judges, Committee, and visitors were entertained at luncheon by the President of the Association, G. Baker, Esq. The new class of Hybrid Teas was not shown in by nurserymen. Two boxes were entered by amateurs, the H.T.'s shown being, of course, Cheshunt Hybrid; Beauty of Stapleford, good substance; and Reine Marie Henriette, the most promising of new Roses.

THE PRIMROSE, POLYANTHUS, AND OXLIP.

THE ENGLISH OXLIP, fig. 4 (*Primula pratensis*, Nobis; *P. veris* β *elatior*, Linn.; *P. vulgaris*, var. *caulescens*, Bab.).—This is the true English Oxlip. It is the Oxlip of Shakespeare and other poets, and is not to be confounded with another plant which is very rarely met with, called the Bardfield Oxlip, which is the *Primula elatior* of Jacquin, but not the *Primula veris* β *elatior* of Linnæus, although the latter is generally given as a synonym of the former. I have examined the specimen in the Linnæan herbarium, where it is marked *Primula veris pallido flore elatior*, and there cannot be a doubt that our English Oxlip is the *P. veris* β of Linnæus.

The true English Oxlip is perfectly distinct from either a Primrose or a Cowslip. Its flowers are numerous, forming a spreading umbel on a tall, nearly smooth, or slightly downy scape rising from the centre of a rosette of leaves. Corolla flat, with five cordate deeply notched segments, the edges of which are dis-

tant or slightly convergent, and there are five narrow deep yellow lines round the throat, forming a five-rayed star. Calyx-tube tubular, as long as the tube of the corolla. Leaves like those of the Primrose, with winged petioles, and sometimes, like those of the Cowslip, with the blade terminating abruptly.

Some botanists assert that the Oxlip is a mere form of the Primrose, and distinguish it as *Primula vulgaris* var. *caulescens*; and others hold that it is a hybrid between the Primrose and the Cowslip. I at one time was of the latter opinion, being very much guided by the views of others and not by facts. Sub-

sequent experience has convinced me that I and others holding that opinion were wrong. I now consider the true Oxlip a perfectly good species, a permanently distinct individuality. All that has been said and written about it being a hybrid is mere conjecture. I have never known nor heard of anyone who has hybridised the Primrose and the Cowslip and thereby obtained an Oxlip or anything else. My excellent friend Col. R. Trevor Clarke, than whom there is no more skilful hybridiser or more careful observer, has stated over and over that he has failed to cross either of them with the pollen of the other. If, then, after

Fig. 4.—THE OXLIP.

careful manipulation they refuse to intercross by artificial means, what reason is there for supposing that fertilisation takes place naturally? There are no conditions in their natural state which cannot be secured in a state of cultivation; and after all efforts have failed to cross them artificially, I am led to the conclusion that the Oxlip is not a hybrid obtained between the Primrose and the Cowslip, but is rather a form produced by organic development in the same way as other new forms are produced in plants by bud variation and other processes of dimorphism or evolution of

the parts, and of the origin and cause of which we are as yet ignorant.

In the third edition of the "British Flora" Sir W. J. Hooker is decided in the opinion that all three plants—the Primrose, the Cowslip, and the Oxlip, are quite distinct. He says, "Few plants can be more constant to characters here laid down than these are as generally seen growing in their wild stations. They rarely are found intermixed, and in Scotland the two last kinds are scarcely known." It is true Professor Henslow had stated that

he found a Primrose which had both pedicellate and seapigerous flowers; but that was, I presume, only one instance of the variations to which the Primrose is subject, and which will be referred to when I treat of the Polyanthus; whereas the Oxlip is found over the greater part of temperate climates true and fixed to its character, not a specimen here and there, but in tolerable abundance. By way of better identifying the true Oxlip I propose to name it *Primula pratensis*, and to allow elatior to remain as the distinguishing name of the Bardfield Oxlip.—PHILANTHOS.

(To be continued.)

LECTURE ON THE PELARGONIUM.

BY SHIRLEY HIBBERD.

THE following is the text of the lecture delivered by Mr. Shirley Hibberd in the Council Chamber of the Royal Horticultural Society on the occasion of the Pelargonium Society's annual Exhibition, June 29th.

The Pelargonium affords a subject large enough to occupy as many hours, days, or even weeks, as the mere moments I shall devote to it on the present occasion. The plants on the table represent in part the beautiful collection of species and hybrids in possession of the Royal Horticultural Society, the management of which at Chiswick is all that can be desired. It is fortunate I am not bound to mention Geraniums, for, if they are of less importance than Pelargoniums they take us further back in time, and to do justice to them we should have to rummage amongst the old books and fish up some very curious memoranda. But the mention of the Geranium renders it necessary to begin with definitions. A Pelargonium is not a Geranium, although often so called. The true Geraniums are for the most part herbaceous plants inhabiting the northern hemisphere, and the Pelargoniums are for the most part shrubby or sub-shrubby plants of the southern hemisphere. Let us for a moment wander amongst the pleasant slopes of Darley Dale in Derbyshire, or by the banks of the Clyde or the Calder. We shall in either case be rewarded by seeing vast sheets of the lovely Meadow Crane's-bill, *Geranium pratense*, a true Geranium, and one of the sweetest flowers in the world. In the rocky recesses of Ashwood Dale, or on the banks of the "bony Doon," we may chance to see in high summer, a profusion of the Herb Robert, *Geranium Robertianum*, with pink flowers and purple leaves, a piece of true vegetable jewellery. And, once more, I invite you to an imaginary journey, and we will ride by rail from Furness to Whitehaven in order to behold on the railway bank, more especially near St. Bees, a wondrous display of the crimson Crane's-bill, *Geranium sanguineum*, which from July to September forms solid sheets, often of a furlong in length, of the most resplendent colour.

Now let us fly to the other side of the globe and alight in the vicinity of the Cape of Good Hope, say on the vast desert of Karroo, where there is much sand, much sunshine, and little rain. Here, in the midst of desolation, the world is rich with flowers, for the heathy scrub that occurs in patches, glowing with many bright hues, consists in part of wild Pelargoniums, which often take the form of miniature deciduous trees, although in the valleys nearer the coast, where more rain falls, they are evergreen bushes.

Very different in their characters are these two tribes of plants, and they are not less different in their constitution and aspects. We may regard the Geraniums as herbs of Europe, and the Pelargoniums as miniature trees of Africa. When we examine the flowers we find the five petals of a true Geranium of precisely the same shape and size; but the five petals of a Pelargonium are not so, for sometimes the two topmost are the largest and stand apart from the rest. The florists are doing their utmost to obliterate the irregularity of the petals of the Pelargonium, and in this respect to convert Pelargoniums into Geraniums, but the conversion will not be complete until much more wonderful things are accomplished. A Geranium has ten stamens, and a Pelargonium has only seven. These numbers are not constant, but the exceptions are of no consequence in a general statement of the case.

When all is said that can be said about the differences and resemblances of the several families of Geraniaceæ, there remains only one constant and unfailing test of a true Pelargonium, and that is the nectariferous tube immediately beneath the flower, and running down one side of the flower-stalk.

The best short summary of the history of the Pelargonium I have met with is in the *Gardeners' Chronicle* of October 2, 1841. It gave me a clue that I wanted to the first-known Pelargonium as an inmate of an English garden. It speaks of one known to Gerarde, but there is no mention of it in the Gerarde of 1597. However, at page 948 of Johnson's Gerarde of 1633 is a record of a plant called *Geranium indicum*, "as of late brought into this kingdom by the industry of Mr. John Tradescant;" and the author adds, "I did see it in flower about the end of July, 1632, being the first time that it hath flowered with the owner thereof." The plant figured by Sweet as *Pelargonium filipendulifolium* (L., 85) is a variety of *Pelargonium triste*, which is identical with the Indian Geranium of Johnson's Gerarde. Thus we determine that the first flowering of a Pelargonium in this country occurred nearly 250 years ago.

Here it may be proper to remark that there are a few true Pelargoniums that are not natives of the Cape of Good Hope. *P. canariensis*

is a native of the Canaries; *P. australe* comes from the Australian continent; *P. cotyledonis* is found wild in St. Helena; *P. Endlicherianum* is Asiatic and almost European. There are two or three species in Abyssinia. But *P. triste* is a Cape plant beyond a doubt, and it is most agreeable to know that our first Pelargonium was brought into the country by John Tradescant, of whom Parkinson speaks as that worthy, curious, and diligent searcher and preserver of all Nature's rarities and varieties. It was in all probability amongst the treasures acquired in his voyage to Barbary, in the fleet sent out against the Algerines in 1620. When, in 1629, he became gardener to Henrietta Maria, Queen of Charles I., this plant was in his famous collection at Lambeth, and was thence sent forth as the pioneer of the Pelargoniums and the Pelargonium Society. As the Cape was discovered in 1497, the plant had 123 years to complete the journey to the Mediterranean, and no doubt had the help of Portuguese traders in so doing.

It is singular that John Tradescant, who was an Englishman, born in Worcestershire, and probably of French extraction, was always regarded as a Dutchman. It is singular in this connection, because subsequent to his introduction of the first Cape Pelargonium, the Dutch were certainly the introducers of a dozen or more species that soon after came into Europe. In Dr. James Sherard's wonderful garden at Eltham there were in 1732 half a dozen species. In the second edition of Miller, published 1733, there are twenty species of African "Geraniums," and these are all Cape Pelargoniums. This brings us to the publication by Linnæus of the "Genera Plantarum" in 1737, and the "Species Plantarum" in 1753, when the twenty-five species of Pelargoniums known to him were described as Geraniums for the last time in any work of high authority. In 1787 L'Heritier distinguished them by the signs I have already mentioned. In the "Hortus Kewensis," published in 1812, as many as 102 species and hybrids are described as then in cultivation at Kew, and the list includes *triste*, *grossularoides*, *zonale*, *inquinans*, *lateripes*, *peltatum*, *grandiflorum*, *quercifolium*, and *fulgidum*.

The splendid garden varieties of Pelargoniums that afford us so much delight are in a certain sense the creations of human skill. Nature never needed such things and did not trouble to produce them. They are the products of careful systematic hybridising and crossing, and they represent the talent and perseverance of the florists during a period of sixty-five years—a period so brief considering what has been accomplished that it shrinks to a moment when we compare the original wildings with the splendid flowers of this day. In the year 1815, or thereabouts, the amateurs began to cross the species, and one of the leaders in this delightful work was Sir Richard Colt Hoare, who obtained a considerable number of beautiful hybrids. The work was taken up with more serious views by Mr. Robert Sweet, the author of a number of valuable illustrated works, comprising one in five volumes devoted to the Geraniaceæ.

The large-flowering or florists' Pelargoniums are reputed to be the offspring of *P. speciosum*. It must be evident to every cultivator of these flowers that the blood of a score or so of species is mingled in them. *P. speciosum* was introduced in 1794, but it has no place under this name in Sweet or the "Hortus Kewensis." It is variously described as producing purple and white flowers, and can scarcely be said to have a history. If the question be asked, What is *Pelargonium speciosum*? I must refer to Sweet's description of *P. involucratum*, No. 33. He there refers to *speciosum* of Andrews as identical with his own *superbum*, and he puts the *speciosum* of Willdenow out of court altogether. It is likely, I think, that *P. spectabile* (136), a hybrid raised from *P. cucullatum* and *P. ignescens*, and *P. involucratum* (33), raised from *P. cucullatum* and *P. superbum*, were the founders of the florists' race. Certain it is that these typical kinds were endowed with the capability of varying indefinitely, and with a plastic constitution rendering them possible sources of innumerable floral surprises. It is scarcely an exaggeration to say that amongst the true hybrids there are at least fifty that might be the parents of our exhibition race. But to clear up the point is impossible, for in very few instances did the early raisers keep any record that could be referred to for settling questions of pedigree.

The first variety figured as a proper florists' flower was called *Geranium grandissima*, raised by Mr. Widnall of Grantchester. The portrait of this variety appeared in the "Floricultural Cabinet" of September 1st, 1834. It was a pretty flower, with rich dark top petals and warm blush-tinted under petals; but the small size and poor form would exclude it from any collection of Pelargoniums in the present day. What a marvellous advance on this do we behold in the latest flowers of Mr. Hoyle or Mr. Foster! To Mr. Hoyle, no doubt, we must assign the gold medal as the producer by systematic crossing of the finest varieties of the present day.

(To be continued.)

HERBACEOUS GRAFTING.

SUCH trees as Peaches and Nectarines, as all know who have had much experience in their cultivation and management, are peculiarly liable to have their symmetry destroyed by the buds failing to break in certain desired positions, by slugs destroying the growth in its early stage, or blister affecting the foliage and killing the shoots. When trees are thus deprived of growth in certain important parts the mode of filling the vacancies by what

is known by the French as herbaceous grafting is worthy of notice at this the proper time for adopting it successfully. The annexed small sketch shows how the process is carried out. A branch is destitute of a shoot, therefore a growth (D) is taken upright from below the vacancy, inarched (C), and grows in the direction B, and the want is supplied. The work of effecting the union of a growing shoot with a healthy stem is very simple. Make a slit about $1\frac{1}{2}$ inch long precisely as in ordinary budding, but with a transverse cut both above and below the longitudinal slit; raise the bark; take a thin slice from the young shoot or scion, then place the prepared growth under the bark of older wood; secure with matting, and shortly a union will be effected; and in due time, some months afterwards, the new branch may be first cut

Fig. 5.

half through and then severed entirely just below the point indicated by the ligature. This inarching may be done from the present time onwards to September as the growths attain the desired length and firmness.—J.

WORK FOR THE WEEK.

KITCHEN GARDEN.

It is customary in many gardens to leave a breadth of the early Cabbage stumps to afford a supply of young heads in autumn. If a reservation has not been already made, it should be attended to without delay. Plant-out Leeks in trenches prepared as for Celery. French Beans may yet be sown in a warm situation. Make a sowing of Endive, deferring sowing for the main crop until the middle of next month. Sow Lettuce for succession, choosing the Cos varieties as being less disposed to be flabby in dry weather than the Cabbage sorts. Parsley previously sown should be thinned-out to about a foot distance apart, and some of the plants should be carefully lifted and planted in single rows in sheltered sunny positions near the base of walls, where protection can easily be afforded in severe weather. As the ground becomes vacant plant-out Broccolis, Cauliflowers, Cabbage for autumn use, Brussels Sprouts and winter vegetables generally, reserving a good breadth for Rosette Coleworts and winter Spinach, which succeed well after Potatoes or Peas, also the Tripoli section of Onions, which may follow Cabbage or Cauliflower. Small sowings of Turnips at intervals will for the present suffice. Shallots as soon as they indicate ripeness should be taken up, dried, and stored in bunches or otherwise. Attend to training Tomatoes as they advance in growth, removing all the side shoots when the requisite number of fruiting shoots are obtained. Train and peg-out the growths of ridge Cucumbers and Vegetable Marrows as needed. The surface soil should be frequently stirred in suitable weather, and every endeavour be made to accelerate the growth of the crops and retard the weeds, hand-weeding in moist weather being more effectual than frequent hoeing and raking.

HARDY FRUIT GARDEN.

It is of the greatest importance to keep fruit trees free from insects, whether the trees are trained to walls or otherwise, and during such a season as the present this is by no means an easy task. The

removal of the foreright or unnecessary shoots, or stopping them, will in many instances be a means of destroying the aphides, and the shoots so removed and infested should at once be collected and burned. Black aphides on Morello and other Cherry trees are difficult to dispose of, as tobacco water or other destroying agents do not have the least effect unless the insects are disturbed, as they may by gently rubbing the infested leaves, &c., with the fingers, tobacco water or the insecticide being employed, following when the trees become dry with a forcible syringing so as to dislodge the insects. The shoots of wall trees should be secured by nailing or tying as they advance in growth, allowing space for the shoots to swell. Attend to stopping and regulating the growth of bush and pyramidal Apple, Pear, Plum, and Cherry trees. Caterpillars are abundant, for which careful hand-picking is an effectual remedy, and Fir-tree oil, nicotine soap, and fresh-ground hellebore powder will destroy them if effectively applied; and the two first are equally effective against aphides, which are unusually prevalent on Gooseberry and Currant bushes. Cutting the shoots back and burning them will destroy many insects, and will better admit of the application of an insecticide. Raspberries with other small fruit are abundant and must not lack moisture, therefore if the soil be dry apply water copiously and mulch with manure. Strawberries must receive abundance of water in dry weather, and the fruit must be carefully protected with nets.

FRUIT HOUSES.

Vines.—Hasten the thinning of late Grapes; those that have to hang over the winter will require rather more thinning than these not required to keep past November, otherwise they will not keep well when a close damp atmosphere has to be contended with. Check all gross laterals, not allowing them to grow until they crowd the principal foliage, then removing them in such a quantity as to cause a check to the roots, which not infrequently results in shanking of the berries. Remove surplus bunches freely, or if the crop be heavy the Grapes will not be thoroughly ripened. It is false economy to extinguish the fires at this season unless the weather be unusually warm, as gentle fires to maintain a night temperature of 60° to 65° and 70° to 75° will ensure steady progress, and allow of the Grapes ripening in August and early September when there is more sun and light, and they will keep very much better than those that have to be ripened in September and October by sharp firing and at greater cost. Vine borders that are high and dry do not generally receive sufficient water when the Vines are in active growth, as they can hardly have too much if the drainage be efficient from the time the Grapes commence swelling until they are well advanced in colouring. Ventilate freely houses containing Muscats that are ripening, also maintaining a good temperature; even Hamburgs when ripening should have a free circulation of rather dry warm air as Grapes ripened in a low temperature are generally poor in flavour and do not keep well. A brisk heat for heavily cropped Vines ripening their fruit would be injurious, more time being required under such circumstances, and rest should be given by allowing the temperature to fall to 60° at night. Houses in which the Grapes are ripe should be kept cool and well ventilated. Vines from which the Grapes have been cut should be syringed every evening to preserve the old foliage as long as possible, and air should be admitted freely night and day. Young Vines will require syringing in the afternoon of bright days, closing the house early with a moist atmosphere to secure free growth, encouraging surface-rooting by frequently supplying tepid water.

Figs.—The first crop will now be gathered, and the trees will require generous treatment, affording liquid manure to the roots, especially such as are in pots or borders of limited extent. As the crop is likely to be large thin freely before the fruits are as large as walnuts, reserving those nearest the base of the shoots. Syringe twice a day to keep red spider in check. Tie-in the growths to the trellis as they advance, stopping such as are not required, and regulate them to ensure exposure to light and air. In houses where crops are ripening, constantly maintain a circulation of dry warm air to ensure the Figs ripening perfectly. Trees in pots intended for early fruiting next season must not now be neglected; syringe them overhead at least twice a day, and supply them with liquid

manure composed of a handful of guano to three gallons of water. When the trees have fully matured their growths in the forcing house they may be placed outdoors in some sunny corner to harden, but it is well not to do so too early, or not at all unless the growth is well matured.

Melons.—As the houses become cleared of their crops remove the old plants, and make preparations for a fresh start. The soil should be removed entirely; and where bottom heat is solely supplied by fermenting material a portion should be taken out and some hot dung worked in, so as to revive the bottom heat. Similar remarks apply to pits and frames. Plant on mounds or ridges rendered firm, and maintain a moist genial atmosphere. Pot off seedling plants, and keep them near the glass to secure sturdiness of habit. Continue fertilising the blossoms of plants that are flowering, and during dull weather ventilate at night, as moisture from condensation during that time will settle on the blossom and be fatal to setting. Directly the fruit is set and swelling earth-up the roots, and keep the laterals closely pinched, thinning out the growths where too crowded. Syringe every afternoon early, maintaining a good moisture by frequent damping, and afford liquid manure to plants with swelling fruit. Close early with a good sun heat. Ventilate at above 75°. Shade only to prevent flagging, paying particular attention to this in bright weather following a dull period. Watch for canker at the collar, and if it appear rub the affected parts with quicklime at once, as when it becomes established it does great mischief in a short time. If the fruits commence cracking reduce the supply of moisture both at the roots and in the atmosphere, and cut the stem half or three parts through below the fruit, and admit air freely, especially at night.

Cucumbers.—The present is a good time to sow a few seeds for late summer and autumn fruiting, about three to four weeks being required to secure sturdy plants. Make the necessary preparations by collecting the fermenting material and soil, and thoroughly cleansing the house. Although no fire heat is now required a gentle bottom heat in the case of new beds is desirable. Test the heat of the beds before planting, and do not plant until the heat has reached its maximum and is on the wane, it not being safe above 90°. Afford liquid manure copiously twice a week, maintaining plenty of atmospheric moisture in hot weather. Fumigate against aphides and thrips occasionally, and employ the knife freely. Train, stop, and thin-out the old growths and foliage in pits and frames, earthing-up the roots, removing the lights for a few hours on showery afternoons. Sprinkle the plants overhead at 4 P.M., closing the lights at that time. Ventilate early in the day, and shade only to prevent flagging.

TRADE CATALOGUE RECEIVED.

Samuelson & Co., Banbury.—*Illustrated General Catalogue of Agricultural and Horticultural Implements.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Fuchsias not Thriving (E. H. O.).—Treat the plants as advised in "Work for the Week," cutting back the shoots moderately, and your plants will flower finely again over a lengthened period.

Primroses (Mrs. Daubeny).—If you send a reminder to "PHILANTHOS" a month hence, when the seed will be ripe, and enclose two stamps, your wish will be complied with.

List of Market Prices (R. Sutcliffe).—When the list you refer to is not published you may take it that the prices remain as before. Your request shall have our attention.

Zygopetalum Mackayi and Cattleya labiata Unhealthy (An Orchid Lover).—The spots on the Zygopetalum leaves are due to excessive moisture, especially at night. Allow the leaves to become dry before night, and admit air more freely. The Cattleya probably requires more moisture, or the buds may have been destroyed. Place it in a warmer temperature.

American Blight on Apple Trees (A. Z.).—If you dip a small brush in paraffin and touch the affected parts, not applying the oil to the smooth por-

tions of the bark, nor in such quantity as to run down the branches, you will destroy the insects and not injure the trees.

Market Garden Crops (Z. V.).—The landlord is undoubtedly entitled to a valuation for the crops upon the ground when you take the lease, unless there is some special stipulation to the contrary. That is, presuming you take the lease immediately of the landlord and not of a previous tenant.

Propagating Ericas (A. B.).—If you have been careful in selecting vigorous half-matured cuttings, they will soon produce roots under the treatment you mention. Especial attention to watering is needed, as they are very liable to "damp off" even when rooted. Wipe the condensed moisture off the inside of the bellglasses daily, and remove them as soon the young plants are making growth.

Growing the Cape Gooseberry in Pots (Subscriber).—It will succeed admirably in a pot, being shifted on as it requires more root room, or it may be kept in a pot of about 10 inches in diameter, supplying liquid manure freely after the roots have filled the pot. The shoots may be stopped to induce a branching habit. The plant must be trained to a trellis or wall, and have plenty of light and air.

Stopping Young Vines (Idem).—Stop the leading stem at the top of the house, allowing the laterals to extend as far as space will admit, but not allowing them to crowd the principal foliage.

Grafting Vines (Querist).—Both the varieties you name will succeed on the Black Hamburgh stock, but we prefer the Muscat of Alexandria on its own roots. This fine Grape also, owing to its free root-action, forms a valuable stock for other varieties. The other white Grape to which you refer is good in some soils and districts, but not in all. You might try a Vine of it, and if it answers your expectations you could quickly increase it by inarching or grafting.

Thrips on Cucumbers (Viper).—Fumigating, not strongly but frequently, will destroy thrips; but if the plants are much infested you had better first syringe them with a solution of soft soap, Gishurst compound, or some other insecticide. A safe strength is 2 ozs. of soft soap to a gallon of water, adding a quarter of a pint of tobacco liquor, and applying at a temperature of 100° to 120°. Fumigation should be done on two consecutive nights at intervals of ten days.

Melons "Bursting" (Ebor).—It is a result of excessive vigour, but it not infrequently arises from a too moist and close atmosphere. The best remedy is to cut the stem about half way through below the fruit to check the flow of sap, and supply water at the roots only to prevent flagging, keeping a dry atmosphere by a free circulation of air at night as well as day.

Flowering Plants for a Room (Sussex).—The most suitable plants for flowering during the winter and spring would be such bulbs as Hyacinths, Narcissuses, Jonquils, Snowdrops, &c., and of miscellaneous plants Pelargoniums, Fuchsias, Cinerarias, and Calceolarias with many others. Annuals are not generally suited for windows. You will find full particulars upon this subject in "Window Gardening for the Many," published at this office, price 9d., or post free for ten penny stamps.

Storing Bulbs (Saxony).—If such bulbs as Hyacinths and Tulips are not removed from the beds until the foliage is considerably withered all that is required is to spread the bulbs on mats and dry them gradually, and then store them on shelves in a dry cool room until they are required for planting. If the plants have to be removed before the foliage is quite yellow, but yet changing, they may be laid in rows in trenches on a border for a few weeks, the roots being well covered with soil, and then dried and stored as indicated. Such bulbs as Crocuses and Snowdrops are often best left in the ground, and if they are near the margin of beds they do not interfere with the summer flowers. Generally speaking, flowering bulbs require the same care in drying and storing as Onions.

Mildew on Vines (G. W. B.).—The leaves sent are infested with mildew, and you cannot adopt a better or safer plan for destroying it than dusting every speck with sulphur. It usually adheres the best when applied very early in the morning before the ventilators are opened, as the foliage is then slightly moist. If this is not so you may syringe lightly, and shortly afterwards apply the sulphur, dusting it through a muslin bag. Some cultivators mix sulphur in water and apply with a syringe. The Strawberry resembles Sir Joseph Paxton, but it is difficult to determine the name without seeing a growing plant.

The Celery Fly (R. T.).—This insect is the Tephritis onopordium of entomologists; it is the larvæ which burrow in the substance of the leaf, and when fully grown pass from the plant to the ground, where they undergo the usual pupal changes, the result being the production of a small winged fly-like creature that is in its perfect state during early summer. The grubs are found in the leaves from June till October, as several distinct successional broods are produced. As your plants are now left unmolessted you may conclude that the larvæ have passed to the ground, but it is by no means certain that the plants will not be again attacked by later broods. Pressing the leaves between the thumb and finger is the only means of destroying the grubs.

Pelargoniums for Winter (Novice).—We presume your plants are of the Zonal type; if so, and they are free-flowering varieties, you will have no difficulty in flowering them from November onwards, provided you have a light house and can maintain a temperature of from 45° to 50° during the period you name. Presuming you have young plants, which are the best for the purpose, they should be placed in clean well-drained pots, employing a compost of rather heavy turfy loam and about one-fourth of decayed manure, potting rather firmly. They should be placed in a well-ventilated frame for a time until they are established in the new soil, when they may be partly plunged in ashes in an open situation outdoors to promote sturdy growth. The shoots may be stopped once or twice, and the flower buds should be removed during the summer. Water them carefully yet sufficiently, as it is important to keep the root-action vigorous, but lessen the supply somewhat in September, and place the plants under glass before heavy autumn rains occur. If you plant them out you will fail in your object. Amongst the varieties for this purpose few are more useful than the old scarlet Vesuvius and its white and salmon varieties.

Stephanotis Culture (S. C.).—It is a stove plant, but succeeds in an intermediate house, and even in a greenhouse during the summer if the air is not too dry. It requires copious supplies of water during the period of growth, and frequent syringings to keep it free from insects. If you withhold water gradually in September you may possibly preserve it through the winter in the warmest part of your greenhouse, but the pot should be pretty well filled with roots at that time, and the soil must not be kept too moist, neither extremely dry.

Culture of Statice profusa (Young Gardener).—The specimen you sent was a portion of this beautiful greenhouse plant, which when well grown is one of the most useful for decoration in the conservatory, the flowers being so

extremely durable. The plant should be grown in a soil consisting principally of fibrous loam, with small proportions of peat, leaf soil, well-decayed manure, with sufficient sand and small pieces of charcoal to render the whole compost moderately open and sweet. Early spring is the best time for potting, an operation which requires some care to prevent undue injury to the roots, or success will not be easily attained. Attend carefully to the supply of water, especially immediately after giving the plants a shift, as they are equally as impatient of excessive moisture as of drought. While in growth an increase in the temperature, with more liberal supplies of water and frequent light syringing, will contribute greatly to their health. While in flower, and afterwards, however, less heat and moisture are requisite, an ordinary greenhouse temperature being suitable. Statice may be readily increased by cuttings of the young shoots inserted in sandy soil under a bellglass in moderate heat, the "striking" being sometimes accelerated by adding a few pieces of charcoal to the soil.

Cucumbers in Greenhouse not Thriving (*Five-years Subscriber*).—The plants are evidently suffering from defective root-action, caused probably by the heavy early cropping, which exhausted the plants. Remove as much of the surface soil as can be done without injury to the roots, and apply a top-dressing of rather lumpy loam, and water with liquid manure at 90°. Encourage growth by the maintenance of a moist atmosphere, ventilating at 75°, and allow a rise to 80° to 85° or 90°, but with free ventilation, closing the house at 80°, syringing the plants moderately at the same time, and damping available surfaces in the house. Do not syringe in the morning. Allow the plants to extend and to start freely before stopping, and when good growth is being made stop the shoots one or two joints beyond the fruit. Shade from bright sun. On no account must the foliage be allowed to flag, but employ as little shading as possible. Remove all flowers and fruit until the plants are growing healthily.

Morello Cherries Falling (*F. L.*).—It is a consequence of the fruit not stoning, and is generally attributable to a very vigorous growth imperfectly ripened. We have also known it result from a deficiency of calcareous matter in the soil, and in other instances from an insufficient supply of water at the roots. If the tree be very vigorous take out a trench about 3 feet from the stem, and cut off all roots extending beyond that. Return the soil to the trench, mixing about a tenth of old mortar rubbish with it, and render it firm. This should be done in autumn when the leaves are turning yellow, also loosening the soil up to the stem of the tree, and mixing with it some old lime rubbish, mulching with litter. If the casting of the fruit be due to a deficiency of calcareous matter mix some old mortar rubbish with the surface soil as deeply as the roots will admit, which should be done when the leaves are falling. But if it arise from dryness, as may be the case when there is a pathway near that throws off the water from the roots, holes should be made with a crowbar; and a good watering given through the holes when the tree is in flower, and repeated after the fruit is setting, will mostly prove effectual, the holes being filled up with soil, but not firmly. We think, however, that the tree is too luxuriant, and requires root-pruning.

Grapes Scorched (*F. E. P.*).—The injury has been caused by the house having been kept closed too long in the morning. When the sun shines powerfully on the Vines when the foliage is moist scorching ensues, and when, the temperature having been permitted to rise too high, a large amount of air is given at once, the evaporation from the fruit is so rapid as to cause injury. If a night temperature of 65° to 60° is maintained with the top ventilators opened about half an inch, and additional air is admitted immediately the heat increases in the morning, adding to the amount in advance of the rising temperature, you will not be troubled with scorching or scalding, except perhaps during a very hot day occurring after several days of dull weather, when special care is always requisite in the ventilation of vineries. In such a case we have known it necessary to sprinkle the glass with whitewash, applied with a syringe, to break the rays of the sun.

Roses in Pots (*Busy*).—We submitted your letter to an experienced cultivator and successful exhibitor of Roses in pots, and his reply is as follows:—"Your correspondent has acted wisely in following the directions given from time to time in this Journal. We for several seasons exhibited successfully Roses that had been grown in a cold pit 20 feet by 8. The foliage and blooms were all that could be desired, and for growing small plants we consider such a pit is one of the best places for first encouraging short and luxuriant growth. 'BUSY' does not state what size the plants are, but we presume they are small, seeing that a few of them were only had from a nursery within the present year. If the plants are well rooted they should be repotted at once in larger pots, using a compost of strong turfy loam (the top spit from an old pasture that has laid in a heap for at least twelve months) three parts; the other part well-decayed manure and leaf soil, with just a sprinkling of bone dust. Chop and mix the whole well together, and pot firmly, taking care that the balls of the plants are moist before potting. After potting plunge them out of doors in a bed of coal ashes or cocoa-nut fibre, and pinch off all buds as they appear. A good mulching of manure placed over the pots will be highly beneficial, as the rains will wash the properties of the manure into the soil, and strong firm wood will be produced for next season's supply of bloom. Watering overhead, in the absence of rain, after a hot day will keep the foliage clean and refresh the plants. They may be left plunged in this position until the beginning of October, when they should be allowed to become gradually drier, and may be housed for the winter. About three months previous to the time the plants are wanted to bloom they should be pruned—not by cutting short back all the strong wood that it has been the main object during the summer months to procure, but by merely removing the unripened points and weak growths, bending the remainder of the shoots with the points downwards to the side of the pots. This is best done by placing a strong piece of cord around the rim of the pot, and securing the point of each shoot to it. This treatment will cause each shoot to break back quite to the base, thereby giving more shoots and blooms than could otherwise be produced, for all Roses have a tendency to produce two or three strong breaks near the points of each shoot, leaving the base naked. By following these directions your correspondent will, we think, be highly successful another year."

Names of Plants (*Highland Laddie*).—1 is not an Orchid, but *Utricularia montana*; 2, *Epidendrum cochleatum*; 3, apparently *Oncidium luridum*, but all the specimens were very much withered, owing to their being badly packed. (*Nil Desperandum*).—1, Completely withered; 2, *Myosotis dissitiflora*; 3, *Asplenium marinum*. (*F. H. S.*).—The specimen somewhat resembled a poor form of *Général Jacqueminot*, but it was too shrivelled to be determined with certainty. (*A. B. P.*).—1, *Carex sylvatica*, Wood Sedge; 2, *C. divulsa*, Smaller Prickly Sedge; 3, *Luzula congesta*, Roundheaded Woodrush; 4, *L. campestris*, Field Woodrush; 5, *L. pilosa*, Hairy Woodrush; 6, *Melica uniflora*, One-flowered Melick. We only name six specimens in one week. (*W. M.*).—1, *Glaucolus ramosus*; 2, *Teucrium angustissimum*; 3, *Corydalis lutea*; 4, *Geranium striatum*; 5, *Habenaria bifolia*. (*Staines*).—1, *Galium verum*; 2, *Scabiosa succisa*; 3, *Symphlytum officinale*.

POULTRY, PIGEON, AND BEE CHRONICLE.

PEDIGREE IN CEREALS.

(Continued from page 504, Vol. LXIII.)

IN continuation of the subject, we refer to Major Hallett's lecture, who says, as to our third fact, the possibility of producing practical "fixity of type"—"I say practical fixity, because, as the President of the British Association for the Advancement of Science remarked to me at one of our meetings of the Linnean Society, 'If there were absolute fixity of type once produced there could be no further improvement.' With this I cannot do otherwise than agree, and I wish to be understood to mean by 'fixity of type,' simply that which we obtain in pure-bred animals. As one illustration of 'fixity of type,' I will adduce the results obtained in various wheat-producing countries of the world from my original red pedigree wheat. Although grown in vastly different soils, climates, and circumstances, the produce, ear and grain, is, with slight modifications of colour, perfectly identical with that grown in the United Kingdom. In the Paris Exhibition of 1867, for instance, amid all the specimens of cereals from the various countries, I at once recognised in scores of instances my own original red pedigree wheat before referring to the catalogues. Another instance of 'fixity of type' I find in the case of Colonel Le Conteur's 'Belle Vue Talavera' wheat. For very many years his object was to improve the quality of his grain. He paid no regard whatever to increasing the number of ranks in the ear; and so, while for years pursuing his own particular object, he incidentally 'fixed' the size of his ears of wheat, and it alone, of all the hundreds of varieties of which I have experimented upon, has refused for eight consecutive years to move beyond the eleven ranks peculiar to it. To show that he certainly did fix the type of his ear, I find those which he sent me are absolute fac-similes of those which I saw in the Museum of the Royal Agricultural Society in Hanover Square, and which were contributed by the Colonel about the year 1840."

After these quotations we must ask the home farmer to consider how far the experiments related can be turned to his own account in the growth of grain upon the home farm. Now we know that there has existed for ages a certain fixity of type, which is shown by the varieties of wheat which are offered for sale, such as Australian white wheat, Canadian wheat, wheat imported from India, Russia, Egypt, and other parts; in fact, we have white wheat, red wheat, white and red-chaffed wheat, rough and smooth-chaffed wheat, bearded wheat, winter and spring wheat, &c. In all these fixity of type has gone no further than deciding the colour of the grain and chaff, the quality of the grain, &c. The practical farmer will say, "I find such or such a variety of wheat suits my soil and climate best, and the same remark applies to barley or oats." There are further reasons for a choice of sorts, that of quality of grain and value to the miller being of great importance, especially in certain districts. An instance of this we find at Guildford in Surrey, where the best quality of white wheat is grown, and when grown upon certain soils in that neighbourhood the grain has a value which can be obtained nowhere else, except, perhaps, a few samples which reach Mark Lane, the metropolitan market, but grown in the same neighbourhood. The two varieties of wheat commonly grown for the Guildford market are "Chidham" and "Trump." These sorts are especially beautiful, and of great weight per bushel, as we have noticed when we have acted as judge of the

grain exhibited for prizes at the Guildford Cattle Show at Christmas time.

Now in certain favourable seasons, although the quality is very fine, the crop and value of the grain per acre good, yet there is the practical question of pedigree in cereals to be considered, which is this: We grow a certain crop (say of wheat) of forty bushels per acre, and we wish for more. How is more to be obtained? Outside the question of pedigree we have sown the best sample which we could obtain, and prepared the soil for the crop in the best possible manner both by tillage and manure. It is quite clear, however, that we cannot grow more ears in number, and if not, how can we obtain what we require? for we cannot sow more than the customary quantity of seed; if we do we shall get only green fodder, or a laid or lodged crop, instead of grain of good quality. The number of ears per acre cannot be increased, for in case we drill one bushel, or sow broadcast two bushels per acre, we can only reap about one million ears per acre. Pedigree, however, comes to our aid, and shows that the only means of increase is by increasing the size and contents of the ears, and this has certainly been effected by the system of selection pursued by Major Hallett in producing his pedigree grain, whether of wheat, barley, or oats, and these have, we assume, if properly cultivated in every respect, just the same tendency to produce large ears as pure-bred Durham cattle have to produce their like progeny. To produce these results we have, however, to consider the period of sowing, and we know that the customary seed time has been very much delayed from various circumstances during the last thirty years. We can recollect when at certain fairs held in August it was customary to purchase the seed wheat of the previous harvest, and to sow it at the end of the month, or in the early part of September, according to the soil and climate in which the crop was to be grown.

The chief cause of wheat being sown so late is the feeding off roots upon the land, or the clover lea ground being reserved and fed with sheep, and other causes. If, however, the home farmer decides to grow pedigree grain thin drilling must be resorted to, say one bushel per acre, sown early in September, and the distance between the rows should not be less than 10 or 12 inches; there will then be not only room for effectual horse and hand hoeing between the rows, but the plants will have plenty of room to tiller. Thus, without any crowding, ears of full size will be obtained, for it must be remembered that pedigree corn will throw large ears, when ordinary corn will not do so with any regularity. We do not wish to recommend any variety of wheat; but in case it is found that any particular sort suits the soil on which he farms it is desirable to obtain grain of full pedigree, for it is frequently the case that white wheats of high quality are grown because there is a demand for it at a district market. It should, however, be matter of experiment, taking, for instance, the best pedigree red wheat, and the same of Belle Vue Talavera or other white wheat, such as Essex rough chaff, both of the latter are of the best quality. It sometimes occurs that the red wheat will realise the most value per acre, and especially when grown near manufacturing and seaport towns where there is a demand for the red wheats by the millers for the manufacture of a low-priced flour, hence the necessity of experimental comparison.

WORK ON THE HOME FARM.

Horse Labour.—Some horses will be employed in cutting grass with the mowing machine on the pasture or park lands. In those pastures, however, which were first mown for hay the carting and stacking will still be going on; at the intervals when not so employed the tillage of the fallows and the ploughing of land for roots after vetches or the hay crop may still employ some of the horses. As fast as land is ploughed for roots after a green fodder crop it should be worked down with harrows and rolled the same day, not only for the purpose of retaining moisture in the soil, but for obtaining a fine surface, so that the young plants may receive all the benefit which can be obtained from the rain. The finer the land is the longer it will retain moisture, in the absence of which no root crop can flourish, especially of the early sowings. The late sowings, however, will often be greatly benefited by the autumn rains, particularly turnips sown as late as the end of July or the first week in August. Land intended for sowing with permanent pasture grass seeds should be attended to, and kept free from couch grass and weeds, so that it may be clean and fine when the sowing takes place, which may well be done in the second week of August. As soon as the saintfoin hay is carted off the land, and as it is in the third or fourth year when the land is usually broken up for another crop, if it is foul with couch or lop grass it is a good plan to skim the turf with the breast plough or the one-horse paring implement. Burn the turf as fast as it can be collected, for in a dry season the turf may be placed on the fires as soon as cut, because the best ashes will be derived from turf burned in a rather damp state. It should be what is termed stifle burnt—that is, placed upon the fires fast enough to prevent the fire showing on the outside

of the heap; the ashes will then be charred and black instead of being a white or red colour. There is no better way than this of clearing an old saintfoin lea, because, Dr. Voelcker says, the ashes will often contain a considerable amount of potash, besides substances the equivalent as manure to 20 bushels of bone dust per acre. The cost of paring and burning is not more than several ploughings, harrowings, rollings, couchings, &c., would be when fallowed in the ordinary way. There is, however, this difference, that when the turf is burned as fast as cut the insects are destroyed whilst secreted in the turf, whereas they have time and opportunity to escape and remain in the soil when the land is ploughed and tilled in the ordinary way; besides which, paring and burning will destroy a great number of weed seeds which may be near the surface. Nor is it of any consequence what crop follows, because the land will be in good order as a seed bed for wheat, or if preferred it may be fallowed and be sown early with barley or oats in the spring. The crops of hay this year are generally very light and will not require much making. We must ask the home farmer to consider the plan of staking the hay in layers with some sweet oat or barley straw, and when doing so the hay may be carted a day or two earlier, and thus diminish the risk of injury by rain; at the same time it will be found that the straw when trussed out of rick together with the hay will be coloured and flavoured by the heating of the hay, and will certainly make valuable chaff when cut as required either for horses, fattening cattle, or any stock including sheep.

Hand Labour.—As soon as the roots, whether mangolds, carrots, Swedes, or cabbage, have been horse-hoed the hand-hoeing should follow quickly. If the weather should continue excessively dry the plants can be left a little closer than usual in the rows, and in a dry season the wireworms and grubs are sure to destroy many plants, and in fact they seldom leave enough to make up a full crop if set out at the full distance at hoeing time. We find this is more especially the case with the carrot crop, and therefore recommend a plan we always adopt. Instead of setting out the plants in the rows at the usual distance at the time of hoeing we clean the land from weeds, and when the carrot plants attain about the size of the finger we either pull the plants and feed cattle with them, or otherwise if labour is scarce we cut them out with the hoe at the required distance, and when the plants have attained the size stated the grubs will not be able to eat them. The autumn rains, too, will have commenced and stop the grubs in feeding upon the roots. As the crop of clover will be very light we must ask the home farmer to save as much as possible for a second cutting, as this will not only furnish an extra bulk of hay, but the land when sown with wheat afterwards will produce a better crop than it would after feeding sheep on the second crop. The second crop of clover, however, if not required for hay will come to hand well for feeding fattening bullocks in the boxes, or furnish supplementary food for dairy cows, horses, &c., which will be better than risking the making into hay. This was always a favourite plan of ours, for the clover not only comes in at a time for use before the root-feeding commences, but the cattle do well upon it and make an immense quantity of valuable box manure.

The time is now come on many farms to buy the sheep stock; and in the case of purchasing lambs for fattening next winter, they should be dipped to kill ticks and skin vermin, or what is better shear them and sell the wool on or about the beginning of August. The lambs will do much better, especially long-woolled sorts, and make when sold from 5s. to 7s. more per head. This is now a good time to put the rams with the Dorset Down ewes; the best bred Hampshire ewes will also offer to the ram at this time if well fed.

KERRY COWS.

THERE are, I am sure, a good many persons who are situated like myself—i.e., have no way of keeping more than one cow, and are therefore desirous of having a good one: let me, then, give my experience of this valuable breed. I have hitherto kept half-bred Alderneys; but reading a good account of the Kerrys in the Journal, and remembering a great beauty we once had in Ireland, I thought, especially as I had just had some unfortunate experience in Alderneys, that I would try them. I wrote to Ireland, but happening to hear that my friend Dr. Hogg had a good herd of them in Sussex, I wrote to him. The result of our correspondence was his sending me one of his cows in calf for the second time. She is a great beauty, symmetrical in shape, jet black in colour, with very white horns, with limbs like a deer, and altogether quite a picture, she only standing 46 inches high; but her appearance is not the best part of her, for she fully bears out the saying, "Handsome is that handsome does." She calved on February 11th, and in four months after calving she gave us nearly 8 lbs. of butter a week, and two quarts of fresh milk a day besides. I need not say after this that the milk is exceedingly rich and the butter good. She is very hardy, will eat anything, and very gentle and quiet. I do not think I can say anything too favourable for her, and if all the "Streame" herd are like her Dr. Hogg has a very valuable herd, but one he will not long keep if its merits are duly appreciated as they are by—*D., Deal.*

THE SCOTCH FANTAIL.

A SCOTCH Fantail is all action and motion, in this consists its highest merit. Of course, the nearer its tail approaches the perfect English type the better, but anything like flatness of tail is not to be expected in it. The tail feathers are not so numerous or long, and as long as they are evenly set with no break in the centre some approach to the funnel-shape must be tolerated. The bird should be very small, little more than half the size of the English Fantail. A Scotch Fantail of really high and (as the fanciers call it), "nervous" carriage, when not busy feeding or on the nest, is ever walking on tiptoe, while the motion of the throat is so great that its whole body trembles. We must confess that we do not admire what we consider an exaggeration of this carriage. Birds are not infrequently seen which walk backwards, and even fall backwards as if in paroxysms when they attempt to fly; their heads, instead of being thrown straight back till they touch the tail, are then twisted round in an inelegant fashion, and altogether give them an unnatural appearance. A large flight of Scotch Fantails all playing and trembling is indeed a quaint and pretty sight, and never fails to delight and amuse non-fanciers. Our beau ideal of a Fantail is, however, a combination of the two styles, such as is to be seen in the lofts and show pens of a few of the most successful admirers of the breed. Of course the two varieties have been greatly interbred both by those who know what they are about and by those who do not, but often to the loss of the best characteristics of both, or at least to their general confusion. It is not, however, impossible for an expert breeder to produce a strain with the smallness, elegance, and tremulous carriage of the Scotch variety, yet with tails almost as round and flat as those of the English. We have found better results to follow from the union of a very small Scotch cock and a good English hen than from the opposite alliance. Small Scotch hens are not infrequently indifferent breeders and mothers, or at least produce weakly offspring. The Indian strain to which we have before alluded has, we fancy, been bred into some English strains, which occasionally show traces of it. Its peculiarities are a peak at the back of the head and feathers on the legs. We do not admire these additions, especially as they are generally seen combined with heavy heads and necks.

Now as to the colour of Fantails. To our taste there is none so pleasing as white, it seems the natural colour of the breed, for birds of other colours can very rarely, if ever, be found to come up in form to the excellence of the Whites, and almost always bear traces of a cross in no remote generation. Be it observed that the white is not, like the white of fowls, liable to be tanned by the sun. Heat and sun in no way affects its purity, and Pigeons if kept in a clean place with proper baths will always keep themselves clean. The nearest approach to perfect form which we have seen in other Fans is in the Blacks, which have long been cultivated in India or on the Continent. Blues there are too, but generally too large, deficient in shape of tail, and not of a bright blue, but too ashy a colour. All the Reds and Yellows which we have ever seen have been poor in tail, and not really good in colour.

"Saddle-backs" are a curiosity. A small and fine strain of them is said to have been once imported, but whence nobody ever knew. They should be marked like Turbits—*i.e.*, white birds with wings, all save the flight feathers, of one colour, as red, blue, or black. If very perfectly marked they would be attractive, but we cannot say that we have ever seen such; they generally have coloured thighs, which just spoils what would be a sharp contrast. White birds, too, with coloured tails are occasionally seen produced by German breeders. Laced Fantails have all the web of their feathers disjointed like Silky fowls, and are more peculiar than beautiful. None of the sub-varieties after all equal the real White Fantail, and we know no variety which shows to better advantage when grouped in numbers. A fine collection of White Fantails is lovely. For two years at the Crystal Palace fanciers of the breed had a rare treat in the sight of the Rev. W. Serjeantson's four pairs which won the cup for the best collection. Subsequently a ridiculous change in the conditions of this competition required the collection to consist of at least two varieties. Still at the Exhibition of the Peristeronic Society and in a few private lofts may such sights be seen.

As a rule Fantails are hardy, good breeders, and careful parents, though we have at times found Scotch birds of very high carriage neglect their young when half grown. Everything against which they are likely to break their tails should be kept out of the loft and aviary. We may prevent disappointment by informing young fanciers, that though very perfect Fantails are always valuable from being few out of many, birds of mediocrity have no saleable

worth, and a beginner must be content to consign all such to the kitchen.—C.

VARIETIES.

DEATH OF MR. JOHN HUNTER.—It is with much regret that we have to announce the death of Mr. John Hunter, author of "A Manual of Bee-keeping," and well known as a skilful apiarian. He expired from congestion of the lungs on Sunday last the 27th ult. at his residence at Ealing, aged 48.

— RYHOPE POULTRY SOCIETY.—This Society will hold their annual Show of Poultry, Ducks, Rabbits, &c., on the 2nd of August, on the property of Mr. Joseph Lee, between Ryhope and Sunderland.

— THE POTATO DISEASE COMMITTEE.—At the last meeting of the Parliamentary Committee appointed to inquire into the causes of the failure of the Potato crop, Mr. Robertson of Dublin was examined, and in reply to questions stated that he introduced the Scotch Champion potato to Ireland in 1877, when it was a rough potato of a floury nature. It was most prolific, and had given great satisfaction, and since its introduction had become much finer. It is undoubtedly the best potato for a general crop. The next best to that for resisting disease is the Skerry Blue. He did not approve of the American potatoes, and had not tried any Australian seed. Since the Champion potato was introduced it has very much improved. He thought the best means of preventing the frequency of potato disease is a matter for individual enterprise, and a grand field for the agricultural societies to take up and experiment upon, having the result periodically published for the benefit of farmers; such experiments to be conducted by societies on Government farms if possible. He knew the "Major Bowman" potato. There was not much difference between that and the Champion. There might have been some spurious seed introduced into Ireland, but it had not come under his notice. The manure that in his experience was best for a potato crop was composed of sulphate of potash, nitrate of soda, and superphosphate of lime.

— LECTURES ON APICULTURE.—Mr. Frank R. Cheshire, so well known to the readers of this Journal, has arranged to deliver a series of lectures at the Royal Horticultural Society's Gardens at South Kensington. The first lecture will be given on Tuesday next, July 6th, at 3.30 in the Council-room. Subject, "The Wonders of the Bee Hive." It will be illustrated by living Cyprian, Ligurian, and black bees, and also appropriate models and large diagrams. These lectures are given gratuitously in the interest of apiculture, and will be open to all visitors to the gardens. Mr. Cheshire's thorough knowledge of this subject and his clearness as a lecturer cannot fail to make this course both interesting and instructive, and we hope all the lectures will be well attended.

— THE SHOW OF THE ROYAL AGRICULTURAL SOCIETY AT CARLISLE.—The preparations for the reception of stock, implements, and other exhibits at this Show will be completed in another week. According to the regulations, all machinery, implements, and other articles, except carriages and exhibits in the "seeds and model" departments, must be arranged in complete order by the evening of Wednesday, July 7th. On the following day the Stewards and Judges will commence their inspection, and the trials will begin on Friday morning in some fields near Carlisle. The trials specially assigned for this year in competition for the Society's gold and silver medals are of implements and machines for the cultivation of the land by steam or other mechanical force. The gold medals can only be awarded for distinctly new inventions likely to be of practical use. In addition ten silver medals are offered for new implements exhibited at the Carlisle Show, and the Judges are also empowered to make special awards of medals for efficient modes of guarding or shielding machinery, especially when worked by steam, from contact with persons immediately engaged in attending to such machinery while at work. Horses, cattle, sheep, and pigs will be admitted to the showyard on Friday, July 9th, and must all be in their places by four o'clock on Saturday afternoon. The implement yard will be open to the public on Saturday, July 10th, and the entire Show on Monday morning, when the Judges of the stock will commence their work. The prizes are of a total value of £5700.

FOUNDATION FIXERS.

A CORRESPONDENT requests me to try osiers or split osiers instead of wires, suggesting that the latter with soldered pins are quite beyond the reach of cottagers, while the pins could be stuck through the osier sticks. He asks in conclusion that I may give the results in the *Journal of Horticulture*. In reply, I have already tried an equivalent to osiers, using Venetian blind lath split into narrow strips with a gauge cutter. These answer perfectly, but require fixing top and bottom. Osier sticks would no doubt succeed as well or nearly as well, their disadvantages consisting in their being soft and not perfectly straight. The best way to make these is to take a piece of wood the thickness of which is equal to the length of the pins when cut off. Bore holes in this wood at the distance the pins are to be from each other. Lay your little stick or osier over the holes, and drive your pins through it down to the head, and through the made holes in the wood beneath. Cut your pins off on the other side with cutting pliers, for which old scissors may be made to do duty, when the pins will be of uniform length. This plan for cutting the pins will answer if wire and solder be used instead of wood.—F. CHESHIRE, *Avenue House, Acton, W.*

PREVENTING EXCESSIVE SWARMING.

My great object this year has been to keep my apiary within bounds, and I am happy to say I have in a great measure succeeded. Thus far I have had but one natural swarm, while I have greatly strengthened my weak hives by the method of treatment adopted. I do not say that in every case or in every year this method of proceeding can be carried out, but under circumstances similar to my own it may be found as serviceable to others as it has proved to me. I therefore give my experience in detail for the benefit of those who may find themselves in a similar position.

I must premise that almost for the first time in my experience as a bee-keeper every stock with which I entered the winter came out of it healthy and active. Not one of them, however, was very strong, and not a few were very weak owing to the great dearth of breeding vigour and the absence of suitable weather for pollen-gathering in the autumn. Still, I never had a healthier set of bees at the beginning of March. By dint of great attention to feeding where necessary, supplying them with artificial pollen and other precautions, several of my stocks became strong enough by the beginning of June to allow of artificial swarms being taken from them. They had completely filled their boxes with brood and were working in supers. Every bee that could possibly be induced to flit was added to the swarms, which therefore were of considerable weight. These I sent off by rail to various parts of the country.

By this means I was enabled to strengthen liberally several of my weak stocks, although these were fast recovering lost ground. The empty boxes with their abundant brood combs were set either under or over the stocks as circumstances dictated. In a few days such a quantity of brood was hatched out that I was able to drive again and strengthen other stocks. By this means I have contrived to bring my whole apiary so forward that, without any apparent check to progress, I have no single hive which does not give me hope of a fair amount of honey in the great July harvest now fast approaching. Among other advantages I was able to give a splendid box full of brood comb to my one swarm. It is now working in two supers, and I see no sign of royal cells yet constructing. From the box out of which it swarmed I am expecting a second swarm in a few days, although, as it was shifted to a new stand according to my invariable custom, it lost nearly all its adult bees, which found their way to the swarm in the old place.

The season thus far has been very fine. If my bees had been in their usual strength in May we should have harvested here a fair quantity of apple and other fruit-blossom honey. As it is, the hives are well supplied, and I have some good combs in sectional supers. At present the bean fields are in splendid blossom, and the white clover is full of promise. There is hope, therefore, of work for our apicultural societies, and an impetus will be given to bee-keeping such as it greatly needs.—B. & W.

OUR LETTER BOX.

Buttercups on Pastures (W. Brace).—These cannot be destroyed unless the turf is burnt, the land being broken up, cultivated for several years, and laid down to pasture again. Even then they will come again after a few years, because where they are usually found they are indigenous to the soil. When the pasture is cut for hay they cannot be separated from the hay, but when cattle feed on the grass as soon as the plants are high enough the blossoms may be cut off with the scythe. This is quite necessary to prevent the plants producing seed, also to prevent injury to butter, as the buttercups are very bitter and spoil

the flavour, but if the milk is sold for immediate use it will not perceptibly injure it. We have not tried the new weed-eradicating machine, but it would probably answer by pulling off the flower and seed heads where the grass is fed off, but not when cut for hay.

Transferring Bees—Removal of Hive—American Mode (S. U.).—We have always thought that the recommendation to transfer twenty-one days after swarming has been founded upon a superficial understanding of the matter. The new queen usually leaves her cell eight days after the departure of her mother with the swarm, while she often, indeed generally, obtains fertilisation at seven days old; but this time is liable to considerable extension, the eight days even reaching fourteen, and the seven, twenty-one. We are then, at the time proposed, likely to be at work when the young queen is seeking a mate, thus making her loss nearly certain, and in this case our hive must sustain damage or even ruin if we are not attentive. The absence of brood at twenty-one days after swarming is helpful, but honey has generally taken its place, making the combs even heavier and quite as difficult to handle. If the weather has been hot and bright generally since the swarm left, twenty-four days after would be practically safe. The nearness of the old stock to your apiary (half a mile) is the real difficulty, and the removal will be nearly sure to involve some loss. It has been lately stated at a convention of American bee-keepers that if a piece of wood several inches square be stood up in front of the hive's mouth, leaving room between it and the hive for the bees to leave and re-enter, and so kept for several days, that the hive may be then removed even a few yards, and the wood taken away with a certainty that the bees will keep to the new stand. The explanation given is that the wood makes the hive dark within, that its removal admits light which warns the bees before they fly out that some change has taken place. This causes them to mark their location and return to it. The idea is new, and we have not had time to try it.

REMARKS.

20th.—Rain in early morning, damp and misty till noon, fine afternoon and evening.
 21st.—Very fine, calm, and bright sunshine the whole day.
 22nd.—Damp, misty, and dark morning; fair but cloudy all day, with just a gleam of sunshine; rain in evening.
 23rd.—Bright in early morning, dull towards noon, with intervals of sunshine in afternoon, thunder 5.10 P.M., fine evening.
 24th.—Fine and bright until 3.30 P.M., very overcast with lightning and thunder 5.20 till 5.40 P.M., sharp breeze and heavy rain at 5.30 P.M., rain in evening.
 25th.—Very fine and bright until 4 P.M., dark with heavy clouds, lightning and thunder 4.10 till 5.30 P.M., very heavy rain 4.45 to 7.15 P.M.
 26th.—Damp, close, morning, showers before noon; heavy thunderstorm commenced at 2.20 P.M. lasting till 3.20, nearly nine-tenths of an inch of rain in the hour; slight showers in evening.
 Warmer, with heavy thunderstorm rains on two consecutive days.—G. J. SYMONS.

COVENT GARDEN MARKET.—JUNE 30.

THE Market continues to be well supplied, Strawberries and other small fruit arriving in very large quantities.

14	W	Maldon; Dartford.

A GAY BORDER.

IN a former letter I said I would endeavour to give a description of a border which would for a considerable period in the year be gay with bright hardy flowers. It so happens that there is a long border about 4 feet wide which extends all the length of the terrace in front of the windows of my house, and it has been my labour for years to try and make this gay and bright for, say, eight months in the year. Now this is very difficult, and requires much consideration and a rather large outlay for a few years. I freely own that for a great number of years I have failed in my endeavour, and that I am only just beginning to reap the reward of my labours and outlay.

First I tried Roses, and they were the most satisfactory of all. At the back I had standard Teas and Hybrid Perpetuals, then vigorous-growing Perpetuals on the Manetti, then weak dwarf Teas. During the Rose season this border was beautiful, but owing to the poverty of my soil the season was very short, and for the rest of the year my beds were bare. I then became convinced that the front of a house was not the place for a rosery, and that some retired position was far more adapted to these charming plants, and gradually I began to weed-out my Roses. This was not difficult, as the poor soil proved a winding sheet for most, and the hard winters finished-off the others. I have only a few standard Teas left, and my front is devoted to herbaceous plants and bulbs, which succeed much better. But there are a great number of these latter which, though having flowers interesting in themselves, are quite unsuitable for the purpose I am speaking of. Erigerons, Polemoniums, and others have such small flowers that you require to bend over them before you can see what they are like. It is obvious, then, that they are unsuitable for a prominent bed where gay flowers are required.

There are, however, a great number of others which are highly valuable and greatly to be prized. First of all, for the back row I should employ Delphiniums. My idea is, that the plants in the back row should be the highest, the next medium-sized, and the third and fourth decreasing in size. Nothing, I think, is so useful for our purpose for the back row as Delphiniums and the finer varieties of Pæonia. But there is such an enormous number of varieties of these plants that it is well to know what are the best. So far as my experience goes there is no Delphinium among the light blues more beautiful than Cantab and Cambridge. The colour is exactly

the same as the Cambridge blue, and the spikes are huge. Among the dark or Oxford blues are Formosum, Cælestinum Formosum, Madam Patey, and Coronet. There are, of course, numbers of lilacs and lavenders, and some nearly white all valuable. Between these Delphiniums I should plant white double Hesperis or Rockets. These are grand plants, something like the Stock but much larger. Also the old Cardinal Plant, Lobelia cardinalis, can be employed, which bears most showy crimson or scarlet flowers, and the still more valuable form Lobelia fulgens. The latter plants bloom later than the Delphiniums, which are preceded by the Rockets. So here we have three shades of colours—white, blue, and scarlet in our back row. I should now add another bright colour—viz., yellow, by employing Helianthus, the Sunflower, which is a late bloomer.

We come now to the next row, and the principal flower I should employ there is Lilium candidum, which I should plant in front of the blue Delphiniums. In front of the Rockets I should plant some few of the darker-coloured Pæonies, and a few light-coloured forms in front of the Lobelias. A few vigorous-growing varieties of Phlox must also be placed in this line. From a large number of Pæonies, all of which are beautiful, I should select as darker sorts Madame Labon, Charles Binder, and Isabella Karlitzki; and as lighter, varying from light pink and primrose to pure white, Monsieur Roussillon, Jeanne d'Arc, Caroline Allani, and Madame Vil-morin. Phloxes are so exceedingly numerous that I scarcely like to select any, but The Bride, The Pearl, The Queen, and Mrs. Turner are indispensable for border decoration.

The next line should principally consist of Bearded Irises and Kæmpferi. The latter bloom much later than the former. Among the Irises I should plant such grand herbaceous plants as Dielytra spectabilis, the worst of this plant being that it requires so much space; Lychnis chalcedonica, Gaillardia splendens, and here and there such charming plants as Aquilegia chrysantha, the Golden Columbine; Aquilegia glandulosa, and A. cærulea, the grandest of all. Potentillas, though most beautiful, are too strong in habit and spread over such a large space of ground that they must not be employed in a border like this, but double Pyrethrums, Pentstemons, and Campanulas may be grown.

The row nearest the walk should contain only very dwarf-growing plants. There is the very place for that useful and valuable florists' flower the Pansy. If I was asked to name the flower which repaid me more than any other for the care we take of it, I should say the Pansy. It continues in bloom so long, is so hardy, bears flowers so lovely in such countless varieties, and takes up such a small space, that too much cannot be said in its favour. For effect perhaps the fancy varieties are the best. The Gentian family, too, are most valuable for this line, as are also Alpine Auriculas, a few Primulas and Polyanthus. Hepaticas, also, are well suited for this position, Alyssum saxatile, Arabises, and other plants of similar character, not forgetting the best species of Iberis that are so effective in spring and early summer.

A most lovely bed and one which would be gay for a long period may be made wholly of bulbs, but I will reserve my observations on this part of the subject for another letter. I am aware that I have omitted a great number of most beautiful decorative plants which would answer the purpose admirably; but in case anyone desires a greater choice I have,

with the assistance of a great grower of these plants, compiled a list arranged as to colour, all of which bear gay and well-defined flowers. All these I can answer from personal experience are worth growing, and nearly all of them are at present in my collection.

White Flowers.

Anemone japonica Honorine Jobert	Phlox The Pearl, Miss Robertson, The Queen.
Hesperis Matronalis alba fl.-pl. (Double White Rocket)	Oenothera taraxacifolia
Centaurea montana alba	Veronica maritima alba
Dianthus Marie Parr	Pansy Great Eastern and Mrs. Felton
Lilium candidum	Saxifraga granulata fl.-pl.
Pyrethrum alba rosea	Arabises
P. Mont Blanc	Alyssums
Spiraea Aruncus	Irises, selected from the aphylla and amœna section of I. germanica.
Campanula persicifolia alba	
Pentstemon The Bride	

Blue, Purple, and Shades.

Aquilegia cœrulea	C. Van Houttei
A. cœrulea hybrida	Echinops ruthenicus, Senecio pulcher, Irises, selected from the Neglecta and Pallida sections of Iris germanica; Pansies in great variety.
Delphinium formosum	This list can be greatly augmented, but the above include the best sorts for the purpose.
D. Belladonna	
D. Nahanni	
D. Barlowi	
D. Hermann Stenger	
D. Madame Lemoine	
Campanula Hendersonii and grandis	

Yellow.

Harpalum rigidum	Coreopsis lanceolata
Helianthus multiflorus	Potentilla Phœbus
Aquilegia chrysantha	Pyrethrum Solfaterre
Rudbeckia Newmanii	Pansy King Koffee
Lilium tigrinum	

Red, Crimson, and Scarlet.

Pyrethrum Progress	Papaver orientale
P. Hermann Stenger	Potentilla Wm. Rollisson
P. carinatum plenum	Centranthus ruber
Dielytra spectabilis	Dianthus magnificus
Geum coccineum fl. pl.	Phlox Deliverance
Tritoma grandis	P. Lothair
Pentstemon Stanstead Rival	P. coccinea
Lychnis chalcœdonica fl. pl.	Monarda didyma
L. fulgens	Lobelia fulgens
Peonies in variety	

—WYLD SAVAGE.

STRAWBERRIES.

UNFORTUNATELY for cultivators the effects of a bad season do not all disappear with it, and signs are not wanting that we have still to suffer, both indoors and out, for the sun's absence during 1879. True, the Strawberry crop indoors has been an agreeable surprise, but I suspect a great deal of the credit belongs to our newly introduced sorts. There are possibly more plants of Vicomtesse Hericart de Thury and President grown in pots than of all other sorts together. Many of us indeed—myself amongst the number—grew nothing else during the season just past, and we have to congratulate ourselves on our choice. Had we stuck to our old friend Keens' Seedling it is more than probable that our early fruits would not have been so plentiful, for Keens' Seedling and its near relatives do not succeed unless they are well ripened, and last autumn we knew that ripening Strawberry crowns was out of the question. Let us not say, then, that our old practice was wrong and that we need not take so much care in the future. I still think it was perfectly right, and that our present success is owing to our possessing more accommodating varieties than we formerly did.

There are several peculiarities about Vicomtesse Hericart de Thury which distinguish it from all the Strawberries, the chief of which are—it will fruit at any time it is required; it is only when forced it can rank as a first-class fruit; it will ripen almost as well without sun as with it; and so long as it is exposed to some amount of air while ripening it is as good gathered out of a hothouse as from an intermediate one, while placing it when ripe in a house with a lower average temperature than 55° actually makes the quality deteriorate, and yet it is only by placing them in a comparatively low temperature with abundance of air that we can obtain the proper flavour of Keens' Seedling and many others. These peculiarities of Hericart de Thury make it altogether the best friend to the Strawberry forcer that he has had introduced

for a long time; and I would suggest to the raisers of new varieties that they take this one in hand and add size to it, which when grown indoors is the only quality it lacks. I have had several fruits this season which would turn the scales with an ounce weight; but these were, I should say, exceptional for this sort, and I have never had the average approach such a weight.

President, in my opinion, is the best variety to come in from the middle of May till the outdoor fruit ripens, it having every good quality at that time; but whatever others may have done, I have never been able to make sure of it before the time named. I still layer all the runners in the fruiting pots, and believe I gain a fortnight's time by so doing, besides the economy of labour in a busy part of the year. And there is another very important thing which is often overlooked: under this system one person can place all the soil in pots for fifteen hundred or two thousand plants, as it does not take long to ram them firm, and one pot is not likely to differ very much from another, while for repotting that number of plants two persons at least are necessary to accomplish it in a suitable time, and no two persons ever can do them exactly alike, consequently the watering which suits those potted by one person may not be just the thing for those done by another. Were I to take charge of a number of plants of any kind, however common and easy to grow they might be, which I wanted to do to the best of my ability, I should prefer potting every one of them myself rather than trust them to be done by the best gardener in England.

The Strawberry seems to be one of the few fruits which are independent of bad seasons. Let the preceding summer be ever so bad, we may be tolerably sure of having some Strawberries in the open ground if it pleases the birds, slugs, and spring frosts. Insects are not troublesome to them, and therefore their cultivation when so many other fruits are a general failure is not likely to decrease. President is without doubt the best midseason Strawberry. Eleanor does well with me for a late kind, but I will not say it is the best for everybody. I am still on the look-out for a better early one than Keens' Seedling, as although it generally does well here it is not without its faults, but I cannot yet see my way clear for discarding it. If a very early variety is wanted Black Prince is undoubtedly the best, but in large establishments Black Prince of less than half an ounce in weight can hardly pass muster close on the heels of President forced to the size of an Egg Plum, and of better flavour than its lilliput brother.

I find the red and white Alpine Strawberries exceedingly useful in autumn, and there are people who prefer their flavour to that of any other Strawberry. Alpines are best treated as annuals. Sown in warmth in February, and planted out in April, 15 or 18 inches apart, they will fruit freely the same season, and continue bearing till frost stops them. Runners planted in spring, having the flowers kept off till July, will do almost as well as seedlings, and can be grown by those who have no house or frame; but in this case, too, a fresh plantation should be made every year if fruit an inch long is wanted.—WM. TAYLOR.

THE RHODODENDRON.

MOST welcome was the note upon Rhododendrons on page 479 of vol. xxxviii. The few sorts named were good, but the list was too brief even for a selection, for there are some of the older varieties so excellent as to be quite indispensable. Such distinct and magnificent sorts as Grand Arab, Barclayanum, Warrior, Geranioides, Queen of the West, Majesticum, and Lady Eleanor Cathcart should never be overlooked, although hardly any of them have had many flowers this year—another of the baneful effects of gloomy, chill, dripping 1879. Lady Eleanor Cathcart has been a brilliant exception with its profusion of bright rosy pink flowers. I have planted several of this charming variety in mixed beds of Rhododendrons, and luckily placed one strong plant on turf near some Conifers and Portugal Laurels to see if it would form a specimen worthy to occupy a conspicuous position; and glad enough am I that this was done, for it and some dozens of other kinds so situated are becoming more shapely and larger than they ever could do in crowded beds. Once established, in two or three years they become a thicket, so that one has to re-arrange and transplant for years in order to give all of them a chance to grow and become fully ornamental. Gladly is this work turned to again and again, for it repays the pains bestowed upon it doubly, affording grand materials for the formation of new clumps, the boundaries of which in turn become enlarged and extended.

The popularity of the Rhododendron is now thoroughly established. Everybody admires it. It forms a prominent feature in every new garden, and is a novel and delightful innovation in many an old one, whence it has routed the dull heavy-looking common Laurel. I lately saw a leading article loud in its praise

in a daily paper. Writers of books of travel often grow enthusiastic in their description of its beauty in a wild state, often insisting that it is never seen in its full splendour in this country, and when they tell of its growing to the size of an Oak tree and being laden with thousands of its gorgeous flowers—a huge mound of vivid colour, we are inclined to agree with them. In Miss Gordon Cumming's charming volumes "From the Hebrides to the Himalayas," there is an account of the Rhododendrons on the Hill of Jakko, Lower Himalayas, one or two sentences of which I must crave space for. "The hill of Jakko is a perfect paradise. It is clothed from base to summit with the richest mixed timber, chiefly the Indian Oak, with a Holly-like leaf, and the dark glossy green of the Rhododendron trees with their gorgeous masses of blossom, the most vivid scarlet, shaded with deep crimson. The only thing to be regretted is, that their glory is so short-lived. Early in May they are on the wane, and by the end of the month a few withered blossoms are all that remain to tell of their bright short lives. But when they begin to flutter down in the breeze they fall like a shower of fire, and alight on the richest carpet of Maidenhair Fern and blue Dog Violets, which everywhere clothe these hanging woods, so that you can scarcely set your foot on the earth without crushing a tuft of such treasures as would enchant the heart of an English gardener."

Such an enchanting scene we may not hope to achieve in the less favoured climate of this country; but we may do much. We have already extended our flowering season to more than twice the length of these grand Hindoo wildings, and my especial object in writing this paper is to urge upon everybody having the requisite amount of space at their disposal to plant some of our best varieties singly in the most favourable situations for their development. Some of the earliest plants of the common *R. ponticum* are from 30 to 40 feet high in more than one garden. Is it too much to hope that another generation may see it become a tree "rivalling the Oak in height?"

Let us also take good heed to turn it to fullest account as a shrub. It is impossible to plant it in the wrong place. On the most *recherché* terrace garden, by the side of woodland walks, by the margin of water, upon the hottest, driest, sunny slope, or the most exposed wind-swept promontory, in the densest shade under the drip of trees, it thrives alike—is equally ornamental; and although it does not bloom when much shaded, yet the deep green finely shaped foliage is always pleasing. Had I to design a large public garden no inconsiderable part of it should be broken up boldly into banks and hollows clothed with Rhododendrons, Azaleas, and Kalmias, with walks winding about among them, and an occasional open plateau commanding the finest effects of massing and colour combinations. This should form a feature of especial importance quite distinct from and shut off from the rest by masses of lofty trees, at once a screen and a foil—a setting of soft green to enhance the brilliancy of the many coloured flowers during the too brief season of their expansion. —EDWARD LUCKHURST.

MR. JOHN DOMINY.

ON opening your esteemed Journal of to-day (July 1st), I was delighted to see such a truthful likeness of Mr. John Dominy, who has for so long been the valued director of the Veitchian nursery at Chelsea. In my humble opinion you deserve the thanks of all horticulturists for having given portraits of two of the most useful gardeners of the time—I beg to use the word gardener in its best and widest sense—Robert Fortune and John Dominy; one a most successful collector, the other apart from his business tact and high cultural abilities, a man who led science by his practice as a hybridiser of Orchids and Nepenthes—the aristocracy of the horticultural world. We have had portraits of gardeners and horticulturists by the dozen, but you have struck a chord of sympathy with those of the two gentlemen I have named, both of whom have done so much in the quiet unostentatious manner so indicative of sterling merit. Poor Robert Fortune died before half the present generation of horticulturists knew his worth; fortunately we have John Dominy still with us. Shall his merit die with him unrecognised by his fellows, or will our brethren give him with their good wishes something like himself—simple, useful, and good, to remind him of the active part in the battle of life through which he has passed, and from which he has so recently retired? All that is wanted is a token of good will from those who recognise his ability or revere him as a staunch and true friend. Those who know Mr. Dominy best will be aware how far his thoughts or wishes are from desiring anything in the shape of a "testimonial," yet anything of a spontaneous expression of good will on the part of his compeers is welcome to any man who feels that he has done his "level best" to deserve

it. That Mr. Dominy does deserve such an expression of respect is beyond question, and I shall be most happy to add my own mite towards such an object.—DUBLINENSIS.

THE NATIONAL ROSE SOCIETY, CRYSTAL PALACE.

JULY 3RD.

ALTERNATE showers and sunshine, which occurred for several

days previous to this Show, are favourable for the development of Roses and especially for imparting a deep rich glossy colour to the dark varieties. We never saw Roses of this

type more bright fresh and beautiful, although we have often seen them larger and fuller, than those staged at this great tournament, for great it was notwithstanding

that there was little competition in some of the classes, while several prizes were withheld. It

will be safe to say that for the majority of growers the fixture, like all other exhibitions of the Society that have been held at the same place, was some days too

early. The Hereford Roses were indeed in fine condition, and consequently the greatest prize ever provided for Roses, the fifty-guinea silver challenge cup offered by Messrs. Cranston & Co. for forty-eight single blooms, was won after a close struggle by Thomas Jowitt, Esq., The Old Weir, Hereford. The first chance for this coveted trophy was secured by R. N. G. Baker, Esq., Heavitree, Devon, in 1877; in 1878 Mr. Jowitt was in the premier position, and according to the conditions only these two exhibitors were eligible to compete for the final possession of the cup in 1879; but as, owing to the extreme inclemency of the weather last year, neither of them was able to stage collections worthy of such a prize, it was mutually agreed that the great Rose duel should be postponed until the present Show. The collections were worthy of the fame of the two celebrated cultivators, and so close were they in merit that the opinions of rosarians founded on a brief examination previously to the judging were about equally divided as to the verdict, the majority being perhaps in favour of the Heavitree blooms. The judging was done with infinite care by the President of the Society (Rev. Canon Hole), Rev. G. N. Pochin, Messrs. G. Paul, Cant, and Arthur Turner. Every bloom was closely examined and its points determined (six points being the maximum for grand flowers), a process which occupied considerably over an hour; when on adding up the figures and giving a certain number of points to the Devonshire blooms for their brilliancy of colour, it was found that something under twenty points remained in favour of Mr. Jowitt. This out of a possible total of 288 shows how close was the race, and intense anxiety was manifested by the members of the Society who were entitled to a private view, which they enjoyed before the verdict was given.

Mr. Jowitt's blooms in the cup stand were Annie Laxton, Nardy Frères, Capitaine Christy, Duke of Edinburgh, Baronne de Rothschild, Mons. Noman (small), Beauty of Waltham, Madame Victor Verdier, Laurent Descourt, Mdlle. Eugénie Verdier, Marie Van Houtte, A. K. Williams (splendid), Duchesse de Vallombrosa, Sultan of Zanzibar, Etienne Levet, E. Y. Teas, Clotilde Rolland, Madame Charles Wood, Dr. Andry, Maréchal Niel, Fisher Holmes, François Michelin, Exposition de Brie, fine; Abel Grand, splendid; François Louvat, Marquise de Castellane, Charles Lefebvre, Elie Morel, fine; Edouard Pynaert, full; Marie Finger, Comtesse d'Oxford, Marguerite de St. Amand, all excellent; Henri Ledechaux, Horace Vernet, rather small; Hippolyte Jamain; Abel Carrière, very rich and good; Madame Lacharme, very fine; Lord Macaulay, Sir G. Wolseley, Souvenir d'Elise, a most beautiful bloom, the premier Tea Rose in the Show, to which was awarded the medal given by Mons. Renaerts of Antwerp; Le Havre, Princess Beatrice, full; Louis Van Houtte, rich, good; Marie Cointet, excellent; Marie Baumann, grand; Madame Furtado, fine; Duc de Wellington, Alfred Colomb, fine; and La France.

Mr. Baker's stand contained splendid examples of Camille Bernardin, Sir G. Wolseley, Baronne de Rothschild, Marguerite Brassac, Catherine Mermet, Exposition de Brie, Marie Baumann, Charles Lefebvre, and Madame Charles Wood a magnificent bloom, as perfect as a Rose can be imagined, of A. K. Williams, the premier H.P. bloom in the Show, and awarded the medal offered by M. Renaerts; Pauline Talabot, Duke of Connaught, Duc de Montpensier, Alfred Colomb, Comte Raimbaud, Annie Williams, Marguerite de St. Amand,

Hippolyte Jamain, Baron de Bonstettin, Madame Lacharme, Marie Rady, all very good; Xavier Olibo, Mons. Fournier, La France, Duke of Edinburgh, Olivier Delhomme, Capitaine Lamure, Duchesse de Caylus, Capitaine Christy, Lord Macaulay, Magna Charta, John Stuart Mill, Fisher Holmes, Le Havre, Star of Waltham, Madame Hippolyte Jamain, Jean Sury, Madame Charles Wood, Hippolyte Jamain, Auguste Rigotard, E. Y. Teas, Ferdinand de Lesseps, Pierre Notting, medium to small; François Michelin and Edouard Morren, rather coarse; Marquise de Mortemart, flat; and a small example of Madame Victor Verdier.

Mr. Jowitt's stand contained, perhaps, fewer extra grand blooms than the other, and also fewer rather small and thin examples; the majority were firm, full, and solid, and, on the whole, it was a very regular and good stand. Mr. Baker's blooms were more variable in size, a few very grand and others too small, but all remarkably fresh and of unsurpassable richness in colour. It was hard to lose with such a stand, but on close inspection the great majority of rosarians accepted the decision of the Judges as being correct, and Mr. Jowitt was duly congratulated on his great achievement.

Continuing the amateurs' exhibits, many of which were highly meritorious, we found eight collections in class of thirty-six single blooms. After an extremely close contest the premier position was won by Mr. James Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, with a very regular stand of medium-sized blooms, but remarkably fresh and well coloured, the foliage also being in excellent condition. The fine Teas gave great weight to this collection, and the bloom of *Innocenta Pyrola* must have run the *Souvenir d'Elise* above mentioned very hard for "premier." Madame Willermoz, Bouquet d'Or, Belle Lyonnaise, and Alba Rosea were all in fine condition; the best of the H.P.'s being Louis Van Houtte, Marguerite Brassac, Madame Victor Verdier, Dupuy Jamain, and Madame Victor Verdier—an attractive and admirably staged collection. Mr. R. N. G. Baker followed, the varieties A. K. Williams, Alfred Colomb, Ferdinand de Lesseps, Baronne de Rothschild, Duke of Connaught, La Havre, and John Stuart Mill being better than any H.P.'s in the first-prize collection, but several others were rather small and thin, while the Teas were few and not of striking merit. The remaining prizes in this class went to Mr. R. N. G. Baker, who was a very close second, Mr. Jowitt, Mr. Davis, The Square, Salisbury, and Mr. Hollingworth, Maidstone, in the order named, all the stands containing some excellent blooms, and several that had not attained to their best condition.

There was great competition in the class for twenty-four single blooms. Mr. Baker was an excellent first, some of the blooms being grand, others small, but all fresh and bright. Of remarkable merit was Ferdinand de Lesseps; E. Y. Teas and Alfred Colomb were fine, and Madame Berthe du Bresnil de Montchateau was especially telling. Mr. Sargant, Reigate; Mr. Jowitt; Mr. W. G. Sharp, Birchin Bridge, Horsham; Mr. Pemberton, Round House, Havering-atte-Bower, Romford; and Mr. F. Warde, West Farleigh, Kent, respectively had the remaining prizes, and the Judges must have had no light task in deciding on the relative merits of the several stands.

Thirteen collections were staged in the class for eighteen single blooms. Mr. Thomas Gravely, Cowfold, securing the ten-guinea silver cup offered by Mr. R. N. G. Baker with very neat, fresh, highly coloured, and compact blooms. Especially rich were Louis Van Houtte, E. Y. Teas, Ferdinand de Lesseps, Duc de Rohan, A. K. Williams, and Abel Carrière, while Marie Rady, Auguste Rigotard, Marie Baumann, and Madame Lacharme were in admirable condition. Mr. Frederick Warde was second with generally larger blooms, the finest being Edouard Morren, Ville de Lyon, Charles Lefebvre, and Marie Baumann. Rev. E. L. Fellowes, Wimpole Rectory, Royston, was placed third with a rather irregular stand, in which La France was splendid, Baronne de Rothschild and Auguste Rigotard excellent, Charles Lefebvre good, and Abel Carrière rich.

In the class for twelve distinct varieties, three trusses of each, there were seven competitors, the general quality of the exhibits being admirable. Mr. R. N. G. Baker gained the chief award with a collection of fresh, even, and brightly coloured blooms, including fine examples of Camille Bernardin, Alfred Colomb, fine; Baronne de Rothschild, Xavier Olibo, Mons. E. Y. Teas, exquisite form; Marie Rady, and Duke of Connaught. Mr. T. Jowitt was an excellent second, his blooms of Mons. E. Y. Teas, Marie Baumann, and Madame Lacharme being very fine. Mr. J. Davis and Mr. G. Sharp were third and fourth respectively with very fair collections.

The class for twelve single trusses was remarkably well filled, no less than eighteen collections being staged, and the competition was very close throughout. The premier position was easily obtained by Mr. J. Ridout, gardener to J. B. Haywood, Esq., Woodhatch Lodge, Reigate, with exceptionally handsome blooms, of good form, substance, and colour, and as fresh as could be desired. The following varieties were capitally represented—Mons. E. Y. Teas, very fine; Comtesse d'Oxford, François Michelin, Duke of Edinburgh, Beauty of Waltham, Mons. Victor Verdier, Charles Lefebvre, Etienne Levet, La France, Marie Baumann, A. K. Williams, and Mons. Crapelet. G. Baker, Esq., Holmfels, Reigate, followed with neat and fresh blooms, A. K. Williams and Marie Rady being notable for their symmetry and colour. The third prize was secured by the Rev. E. L. Fellowes; the fourth, fifth, and sixth being obtained by the Rev. Alan Cheales, John Wakeley, Esq., and T. F. Burnaby Atkins, Esq., Halstead Place, Sevenoaks, all with very neat specimens. In

the class for six distinct varieties of Cheshunt-raised Roses, Mr. T. Jowitt was the only prizetaker, the ten-guinea silver cup presented by Messrs. Paul & Son being secured by him with fair examples of Duke of Edinburgh, Princess Mary of Cambridge, Lord Clyde, Annie Laxton, Cheshunt Hybrid, and Sultan of Zanzibar.

Eighteen collections were staged in the class for nine single blooms. That excellent cultivator, Mr. Ridout, well won the chief position, the most noteworthy flowers being Edouard Morren, Marie Baumann, Charles Lefebvre, Marquise de Castellane, Beauty of Waltham, Ville de Lyon, and Baronne de Rothschild, all of which were fine; a few Teas in the stand being fresh but small. Rev. Alan Cheales, Brockham Vicarage, Surrey, was placed second, his stand containing among other good blooms a charming Niphetos and a rich and compact Charles Lefebvre. Mr. Strange, Aldermaston, Reading, was a very close third with generally larger but less firm and full blooms. The gem of the stand was a charming example of Madame Caroline Kuster. Mr. W. H. Wakeley, Rainham, Kent, and Mr. Edward Mawley, Addiscombe, Croydon, had respectively the fourth and fifth prizes in this class, both staging several compact fresh blooms.

There were six collections in the class for six blooms, E. Horne, Esq., Park House, Reigate, being placed first with fresh, full, and good examples of Charles Lefebvre, Marquise de Castellane, Fisher Holmes, Madame Fillion, Marie Baumann, and Baronne de Rothschild. Mr. Scott, the Treasurer of the Society, Clinton Villa, Wimbledon, was second with a bright and good stand; Mr. F. Burnside, Farningham House, Farningham, third; and Mr. Tranter, Upper Assenden, Henley-on-Thames, fourth.

In the class for six suburban Roses, three out of the four prizes went to Wimbledon. Mr. Scott was an excellent first, winning the silver plate offered by Mr. Mawley with Paul Neyron, not often seen in such excellent form; Capitaine Christy, Etienne Levet, Eugénie Verdier, Maréchal Niel, and Le Havre. Mr. Edwin Saunders, Rose Villa, Palmerston Road, South Wimbledon, was second with neat blooms. Mr. Arthur W. Tyrrell, The Cottage, South Norwood Park, S.E., third with irregular blooms, Charles Lefebvre being splendid; and Mr. John E. Coleby, 8, St. George's Road, Wimbledon, third with large and too much expanded examples. Eight collections were staged in this class.

Five attractive stands were exhibited in the class for twelve Teas or Noisettes. Mr. Hawtrej secured the premier position with clean smart blooms of *Souvenir d'Elise*, *Souvenir d'un Ami*, *Comtesse de Nadaillac*, Catherine Mermet, Adrienne Christophle, bright; Boule d'Or, Madame Lambard, Devoniensis, Rubens? Moiré, Madame Hippolyte Jamain, and Niphetos. Mr. Charles Davies, The Grammar School, Aynhoe, Banbury, was an excellent second, with (amongst others) splendid examples of Bouquet d'Or, Alba Rosea, Catherine Mermet, and Jean Ducher (?). Rev. E. L. Fellowes was a good third, his Catherine Mermet being the gem of the stand; and Mr. Hollingworth fourth. If the two blooms to which attention is directed were correctly named, they afford evidence of how greatly Tea Roses are influenced by soil and climate.

There were also six much-admired stands in the class for six Teas or Noisettes. Mr. Jowitt was originally placed first, but was afterwards disqualified for having by an oversight included Cheshunt Hybrid, which is contrary to the conditions; Mr. Edward Horne was therefore placed first for a charming stand, in which Adrienne Christophle was very rich; Marie Van Houtte, excellent; and neat examples of Catherine Mermet, Maréchal Niel, and *Souvenir d'un Ami*. Mr. W. H. Wakeley, Rainham, was a good second, and Mr. John Wakeley third.

In the suburban class for six Teas the silver cup was withheld, and Mr. Hawtrej was awarded a second prize for the only stand exhibited.

In the class for eight trebles in various stages of development—full blown, half blown, and buds—the first prize went to Mr. Sargant, Reigate (a silver-gilt medal offered by the "Journal des Roses"); second to Mr. A. Evans, Marston, Oxford; and third to Mr. Hawtrej. The first-prize collection was very bright and fresh.

Mr. Jowitt was the winner of the five-guinea cup offered by Mr. Symons, in the class for twenty-four sweet-scented Roses, Mr. Hawtrej being second.

In the open class for twelve Roses not in commerce previous to 1877 Mr. Charles Turner, Slough, had the chief position with Mrs. Laxton, fine; Madame Lambard, small but pretty, with waxy salmon pink petals; Penelope Mayo; Mrs. Harry Turner, of the Charles Lefebvre type; Hon. George Bancroft, large deep rose; Madame Alexander Bernaix, Charles Darwin, Richard Laxton, Madame Emma All, Harrison Weir (small but rich), and Duchess of Connaught. Messrs. G. Paul & Son were second with generally larger flowers; Duke of Teck and Earl of Beaconsfield, very good; and Madame G. Luizet, very effective. Messrs. Cranston & Co. followed, their most notable blooms being Constantin Fretiakoff and Julins Finger, a well-flowered Rose of the Marie Baumann class. There were many small flowers in Rose stands, and more time is necessary for producing the varieties in superior condition. In the corresponding amateurs' class for six blooms Mr. Hawtrej secured the first prize.

In the Maréchal Niel class Mr. Cant was first with twelve blooms, remarkably rich, but not large; they were additionally interesting, as all were cut from the original plant introduced into England in 1864. It is growing on a Briar stock, and is trained to a south wall.

There were seven exhibitors of twelve single trusses of Marquise

de Castellane, the chief prize being gained by Mr. J. Walters for beautiful symmetrical blooms, very bright and altogether excellent. Messrs. Davison & Co., White Cross Nursery, Hereford, were placed second with blooms but little inferior to Mr. J. Walters; and Messrs. Cranston & Co. were third with fair blooms. Mr. J. Walters staged the only collection of twelve trusses of Reynolds Hole, and was awarded the first prize for very fair blooms, neat and good colour. Nine competitors entered in the class for a dozen blooms of any dark Hybrid Perpetual Rose, Mr. J. Walters being first with good examples of Marie Baumann; Messrs. Cranston second with Horace Vernet,

very fine; and Messrs. Paul & Son with Charles Darwin, in good condition. Twelve collections of light Hybrid Perpetuals were staged, the chief prize being secured by Mr. R. N. G. Baker with handsome blooms of Baronne de Rothschild; Messrs. Cranston followed with Madame Lacharme, very fine; and Mr. T. Jowitt with the same variety, very slightly inferior in quality. The only exhibitor of "twelve trusses of any Tea or Noisette not named in the schedule" was Mr. J. Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, the premier award being obtained for Belle Lyonnaise, in superb form. There were only two exhibitors in the class for "three

Fig. 6.—PRIMROSE POLYANTHUS. (See page 30.)

trusses of any new seedling Rose not yet in commerce or announced." Messrs. Paul & Son, Cheshunt, secured the chief prize, which was offered by G. P. Hawtrey, Esq., with R. N. G. Baker, a Hybrid Perpetual Rose of a rich-rose colour, with broad petals, of good substance and form. The second prize was withheld.

NURSERYMEN'S CLASSES.—The six competitors in the class for seventy-two distinct single trusses staged collections, all of which included blooms of good substance, but the majority were neat rather than large and very bright in colour. The chief prize, which consisted of a silver cup presented by John Hollingworth, Esq., and £5 from the Society, was awarded to Messrs. Cranston & Co., Hereford,

for an excellent collection, in which the following varieties were represented. Mons. E. Y. Teas, very fine; Princess Beatrice, Annie Laxton, good; Dupuy-Jamain, a handsome bloom; Xavier Olibo, excellent; Souvenir de la Malmaison, Dr. Andry, Hippolyte Jamain, La Duchesse de Morny, La Rosière, Devoniensis, Centifolia Rosea, very large and good form; Mons. Gabriel Tournier, Jean Cherpin, handsome; Auguste Nieumann, Madame Marie Finger, Sir Garnet Wolseley, handsome flower; Madame Furtado, Fisher Holmes, Mdle. Marguerite D'Ombraïn, Baron de Bonstettin. Marchioness of Exeter, good; Maurice Bernardin, neat; Madame Thérèse Levet, compact; Louis Van Houtte, good; Baronne de Rothschild, very fine; Le

Havre, fine; Madame Hippolyte Jamain, Général Jacqueminot, grand in colour and size; Madame Gabriel Luizet, Etienne Levet, fine; Madame Lareharme, good; Constantin Fretiakoff, fresh; Capitaine Christy, good; John Hopper, Chas. Lefebvre, neat; Comtesse d'Oxford, great size and substance, an exceptionally fine bloom; Jean Liabaud, Mrs. Baker, Duchesse de Vallombrosa, handsome form; Prince Camille de Rohan, Abel Carrière, Niphotos, Jean Sury, Edouard Morren, grand; Beauty of Waltham, very neat and good; Madame Bravy, Horace Vernet, Marguerite de St. Amand, Auguste Rigotard, good; La France, fine; Lord Macaulay, good; Marquise de Castellane, excellent; Madame Chas. Wood, very handsome, fine colour; Elie Morel, Reynolds Hole, Mons. Noman, very large; Duke of Edinburgh, bright; Catherine Mermet, Marie Baumann, large; Cheshunt Hybrid, Jean Soupert, Mdle. Marie Cointet, John Stuart Mill, handsome; Marquise de Mortemart, Ferdinand de Lesseps, Madame Nachury, Alfred Colomb, Mdle. Eugénie Verdier, large and good; Sénateur Vaisse, fine; and Belle Fleur d'Anjou. Messrs. Cranston well deserved the honour they received, for many of the blooms in their collection were exceptionally fine, but they were especially fortunate in escaping the spring frosts which seriously affected the plants of many other nurserymen who are less favoured in regard to position.

Messrs. Curtis, Sanford & Co., Torquay, were second with a fine selection of varieties, mostly the same as those enumerated in the preceding collection. Blooms of the following were particularly noticeable for their excellent quality:—Sénateur Vaisse, Royal Standard, François Michelin, Exposition de Brie, Marie Baumann, Mdle. Marie Rady, and Dr. Andry. Messrs. Paul & Son, Cheshunt, gained the third prize with neat fresh blooms—Marie Baumann and Alfred Colomb being excellent. Messrs. Keynes & Co., Salisbury, were fourth, their blooms being rather uneven and somewhat rough, but several were of good form and colour.

Messrs. Cranston & Co. were again victorious in the class for forty-eight triplets with a handsome collection that included many admirable blooms. Exposition de Brie, Duchesse de Vallombrosa, Alfred Colomb, John Stuart Mill were extremely well represented, and Général Jacqueminot was magnificent. Messrs. Curtis, Sanford & Co. followed with an even collection, very bright and fresh; Messrs. Paul & Son and Messrs. Keynes & Co., the only other exhibitors in the class, receiving the two remaining prizes.

Six stands of thirty-six varieties were exhibited. Mr. James Walters, Mount Radford Nursery, Exeter, was first with a fresh and bright collection, followed by Mr. C. Turner, Slough, Mr. F. Cant, Mile End Nursery, Colechester, and Mr. W. Farren, How House, Cambridge, all with blooms very close in merit. Out of five collections, twenty-four triplets, the chief honours were accorded to Messrs. Cranston & Co., who staged handsome examples of Horace Vernet, Madame Lareharme, Exposition de Brie, Etienne Levet, La France, and Mons. Noman. Mr. G. W. Piper, Uckfield, Sussex, was a good second; Mons. E. Y. Teas, La Rosière, La France, and Marie Baumann being particularly fine. Messrs. Keynes & Co., and Paul & Son, were third and fourth respectively. The competition was especially keen in the class for twenty-four single trusses, nine admirable collections being exhibited. Mr. J. Walters secured the premier award with fine specimens of Abel Carrière, La France, Alfred K. Williams, Marquise de Castellane, Marie Baumann, Ferdinand de Lesseps, and Dupuy Jamain among others. Mr. C. Turner followed with neat blooms well selected. Mr. W. Farren and Mr. W. Rumsey, Joyning's Nursery, Waltham Cross, being third and fourth with fair examples.

Nine competitors entered for twelve Teas or Noisettes, the first prize being secured by Mr. G. Prince, Oxford, with handsome blooms of Anna Ollivier, Marie Van Houtte, very beautiful; Rubens, Alba Rosea, Jean Ducher, Maréchal Niel, Souvenir d'un Ami, Souvenir de Paul Neyron, Souvenir de Madame Pernet, and Souvenir d'Elise Vardon. Messrs. James Mitchell & Sons, Uckfield, were second with a neat collection, Messrs. Paul & Son being third. There were only three entries in the class for six Teas, three trusses of each; the six-guinea silver cup offered by Thomas Hollingworth, Esq., as first prize being secured by Messrs. James Mitchell & Son with very neat specimens of Souvenir d'Elise Vardon, Souvenir d'un Ami, Catherine Mermet, Joséphine Malton, Niphotos, and Paul Neyron. Messrs. Cranston & Co. followed very closely, Marie Van Houtte and Madame Willermoz being especially noteworthy. Messrs. Paul & Son were third with fair blooms.

Among the miscellaneous exhibits were excellent collections of Roses from Messrs. Veitch & Son, Chelsea; Bunyard & Co., Maidstone; Laing & Co., Forest Hill; and Mr. George Prince, Oxford, the latter staging several beautiful boxes of Moss Roses vigorously grown on the seedling Briar. Mr. H. Cannell also contributed cut blooms of Zonal Pelargoniums and Verbenas, which were very greatly admired.

After the judging had concluded a large gathering of the members and their friends assembled in the south dining-room for a *déjeuner à la fourchette*, the Rev. Canon Hole, President of the Society, in the chair. Many of the most distinguished rosarians were present, and Messrs. Ellwanger & Barry, the celebrated nurserymen of Rochester, New York, were amongst the guests. The President, in one of his genial speeches, spoke of the success of the Society and of the valuable services which he as admiral of the ship received from the Secretaries, Treasurer, and Committee, and said that thus served he might go down into his cabin and be quite at ease as to its safety. He then proposed the only toast given, "The visitors," which was appropriately replied to by Mr. Ellwanger, who thanked his

brother rosarians for the kind and hospitable reception they had received, and hoped he might see some of those present at "the other side of the water, when they would be only too glad to show them the same hospitality."

WE append the following critique of the Show by a well-known rosarian, which will be welcome to many readers:—

The great field day of rosarians has come and gone—the day that is looked forward to with as great anxiety and interest by lovers of Roses as the Oxford and Cambridge boatrace is by University men, or the Derby by sportsmen. Perhaps more than the usual interest was felt in the Show this year on account of the great duel between two of the leading amateur exhibitors having to be fought for the final round. The interest, therefore, as to who should finally win the handsome silver claret jug which Mr. Cranston so generously presented was most keen. There was not, so far as I am aware of, any betting on the event, but if there had been I presume it would have been even. Mr. Jowitt has perhaps if anything a stronger Rose soil, but Mr. Baker has the advantage of a milder more genial climate, and certainly a more sheltered position. Whether, then, the cup was to be carried off finally to The Old Weir near Hereford, or was to decorate the sideboard of that most generous host Mr. Baker, this was an issue that attracted more attention than all the rest of the Show together. The Judges, who had the most important and by no means to be envied task, were the men most qualified to fill this post. Most carefully did they perform their task. Every Rose was discussed separately, the number of points to be given to it was decided by the majority and put down on a piece of paper, and when the amounts came to be added up it was found that Mr. Jowitt was the victor in a well-contested fight by a majority of twenty-three, the points being—Mr. Jowitt 182, Mr. Baker 159, but to Mr. Baker's number a few points were, I think, added for general brilliancy of colour.

As a great friend of both gentlemen I shall be very careful what I say upon the issue. As it seems to me, who am entirely unprejudiced and only anxious to give your readers a free and unbiassed opinion, Mr. Baker's blooms were much superior to Mr. Jowitt's in colour, while the latter surpassed him in size and evenness. In form both were equally good. Mr. Jowitt had finer Teas, while Mr. Baker's dark Roses were in some instances much superior. Perhaps the very weakest Rose in Mr. Jowitt's box was Charles Lefebvre, while in Mr. Baker's this was one of the finest. A. K. Williams in this stand was awarded the prize as the premier bloom (H.P.) in the Show, while Mr. Jowitt's magnificent bloom of Souvenir d'Elise was in this cup stand adjudged the same prize as a Tea. The best blooms I noticed in Mr. Baker's stands were, besides the two above named, Thomas Mills, E. Y. Teas, Duke of Edinburgh, Jean Sury, Alfred Colomb, Marie Van Houtte, and Magna Charta; while in Mr. Jowitt's stand, besides the Tea I have before named, there were splendid examples of Marie Baumann, Eugénie Verdier, La France, Marie Van Houtte, Maréchal Niel, Sultan of Zanzibar, Etienne Levet, Baronne de Rothschild, and Mons. Noman.

These stands were in my opinion undoubtedly the best in the Show. The contest is now over, and I daresay not only are the principal persons concerned glad, but I have no doubt they would prefer that it should not be repeated. It becomes almost too personal a fight when it is confined only to two men, however great they may be.

And now to speak of the Show generally. This—I cannot help stating it—was not up to the average. I do not think I ever, except last year when the Show was held so early that hardly anyone could come to it, saw so few nurserymen contend for the great prizes. Mr. Cant was only represented by a box of Maréchal Niel, which were not only very good, but were rendered most interesting by the statement that they were cut from the original plant sent over in 1864, now growing against a south wall at Colchester. Mr. George Paul certainly showed, but was as little like his usual form as a street German band is like the Crystal Palace Saturday orchestra. Mr. Cranston, who secured the first prize for seventy-two, was very fair, but I have seen him show infinitely finer. He astonished everyone, however, with his blooms of the old favourite Général Jacqueminot. There was very great doubt whether one of these blooms would not be selected as the premier bloom, but the Judges, as I said, gave it to A. K. Williams. Mr. Turner exhibited in the smaller classes very well; and Mr. Mitchell in the large classes and Teas; but none of them were up to their old form.

This was not the case with the leading amateurs. Both Mr. Baker and Mr. Jowitt showed very finely. Perhaps the best Roses, at all events in the smaller classes if not in the whole Show, were those with which Mr. Ridout won the first prizes for twelve, nine, and six varieties. These were really grand. Mr. James Walters of Mount Radford Nurseries, near Hereford, whose nursery and Roses I have often described in the Journal, showed remarkably well in the class for twenty-four. He was first in every class for which he competed—first for twelve blooms of Marquise de Castellane and Reynolds Hole, and also first for twelve light Roses. One of the finest boxes I have ever seen staged consisted of twelve blooms of Baronne de Rothschild with which Mr. Baker secured the first prize for twelve blooms of any variety; these were superb. Mr. Prince of Oxford showed a beautiful box of Teas, securing first honours. His Alba Rosea, Jean Ducher, and Souvenir de Paul Neyron were very fine; his Maréchal Niel was a fresh young bloom but rather small, but it had the great recommendation of not disturbing the evenness of

the stand. Mr. Cranston surprised a great many visitors with the marvellous bloom of Madame Charles Wood which he showed in his seventy-two. His other Roses were very fine, but the best were the two I have named, and Horace Vernet, John Stuart Mill, Mdle. Eugénie Verdier, Sir Garnet Wolsely, and Comtesse d'Oxford.

You will have no doubt a complete account of the Show furnished you by your special reporters, so that I need not go into details as to prizes. To sum up, the Show was a very enjoyable one, but not so large as some we have seen, as it was conspicuous by the absence of some great exhibitors, but ever to be remembered as the one at which Mr. Baker and Mr. Jowitt fought their final round in the Palace of Crystal.—WYLD SAVAGE.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 7. NEW SERIES.

THE Hymenopterous order, or what is commonly called the "order of bees," includes many species which are very unlike bees in appearance and habit; it is even true that in the group of the true bees, or "flower lovers," there are necessarily placed species in which there is only slight resemblance to the typical bee. It has been stated that the Hymenoptera are divided firstly into two large sections—those that have no stings, and those provided generally with such a weapon. Having dismissed the former of these already, we now arrive at the last section of the Aculeata, the stinging bees, very numerous, and in size ranging from the big humble bee to the little Sphecodes, which is really about the size of an average ant. We shall refer to these in a future issue, and in the meantime we direct attention to the family Dasygasteræ, which receives its scientific name from the circumstance that the female insects have a mass of hairs beneath the abdomen, which serves as a pollen brush. These bees, according to their different habits, have been called mason bees, carpenter bees, leaf-cutters, and upholsterers; the last group, which line their nests with petals, are not recognised as natives of Britain. Even in the same species we have at times a singular variety of habit; the common mason bee, *Osmia bicornis*, while in certain situations showing itself partial to cliffs or dry banks, elsewhere resorts to decaying tree stumps, or burrows into the mortar of an old wall. *Osmia leucomelana* (fig. 7.) makes choice of dead twigs of Bramble. The mother bee removes the pith for 5 or 6 inches, leaving the intervals to separate the cells. A sufficient quantity of food is placed with an egg in each cell, and the whole is covered up with a vegetable paste, evidently manufactured by the insect. In this instance each young bee can work its way out, not interfering with the cells of its brethren. Other *Osmias* pursue the practice of nest-making in branches or in stumps. A few species, of which *O. aurulenta* is a prominent example, though occasionally burrowers in banks, often save themselves this trouble by looking for deserted snail shells, that of *Helix hortensis* being taken by preference. There the cells, from four to six, are placed in succession within the whorl; but if the bee chances to find an empty shell as broad as that of *H. aspersa* the cells are placed in pairs. The leaf-cutter bees are represented in the genus *Megachile*, and several of these are abundant in gardens; *M. centuncularis*, for instance, the females of which also enter hothouses and conservatories, where they are perhaps erroneously regarded as visitors having designs upon fruit, whereas their object is to take fragments of leaves—the *Geranium* is rather a favourite with them. Out of doors we cannot fail to notice the clean cuts made by this species and its congeners in the Rose, the Privet, the

Fig. 7.—*OSMIA LEUCOMELANA* (A CARPENTER BEE).

Laburnum, and other shrubs. The nest of the leaf-cutters is usually worked in solid earth, and the burrow is formed on the plan of most solitary bees, but it is carefully and evenly lined with pieces of leaf, and the divisions between the cells are of the same substance. The Anthophoræ are another group of mason bees. These, having formed a burrow, line it with a material of their own making, sand or clay softened with saliva. All the bees of this family are smaller than the hive bee, some much smaller, in colour usually dull shades of black, brown, or grey.—C.

RICHMOND HORTICULTURAL SOCIETY.

JULY 1ST.

THIS flourishing Society held its annual Exhibition on Thursday last in the Old Deer Park; and although in the number and quality of the exhibits it was quite a success, yet the unfavourable weather somewhat marred what would otherwise have been one of the best local shows of the season. During the morning and part of the afternoon several heavy storms passed over, but towards evening the weather became more favourable, and great numbers of persons visited the Show. The Princess Mary of Cambridge and the Duke of Teck honoured the Society by visiting the Exhibition during the afternoon, and were conducted through the tents by some of the Committee.

Five large tents were devoted to the exhibits—viz., one to chiefly the special classes for plants, one to the general plant classes, one to fruit and table decorations, one to vegetables, and one to cottagers' productions. The second of those mentioned above contained the most attractive portion of the display of plants, for in it were arranged not only the groups in competition, stove and greenhouse plants, Orchids, Ferns, Pelargoniums, and fine-foliage plants, but there were also several large miscellaneous collections from various nurserymen. The groups arranged for effect were very tasteful, the prizes being obtained by Messrs. Hooper & Co., Covent Garden; Mr. W. Brown, St. Mary's Grove Nursery, Rich-

mond; and Mr. Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton. The latter exhibitor staged a pretty group, that was very similar to the one so greatly admired last year, when he obtained the first prize. Messrs. Jackson and Son were the only exhibitors of nine stove and greenhouse plants, obtaining the chief prize with fair specimens, a *Bougainvillea glabra* being particularly fine. Mr. C. Attrill, gardener to C. J. Freake, Esq., Bankgrove House, Ham, and S. A. Davis, Esq., Anglesea House, Surbiton (gardener, H. Hinnell), had the only collections of six specimens, neat and fairly well flowered.

Pelargoniums were not numerous but in fine condition, being chiefly exhibited by H. Little, Esq., Hillingdon Place, Uxbridge (gardener, Mr. Wiggins); W. Selwyn, Esq., Selwyn Court, Richmond; Dr. Francis, and Mr. Attrill; Mr. Little's plants as usual taking precedence. Ferns were well represented by several collections of handsome plants in vigorous health. Mr. Hudson gained the chief prize for eight exotic Ferns with fine examples of *Davallias*, *Gleichenias*, and a good *Dicksonia antarctica*. J. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. D. East), and J. S. Rutter, Esq., The Cedars (gardener, Mr. B. Morrell), followed with fair specimens. The Rev. W. Finch, Woodlands, Kingston Hill (gardener, J. Crafter), had the best collection of twelve hardy Ferns, Mr. Morrell and Dr. Francis taking the remaining prizes. Fine-foliage plants were shown by Sir H. W. Parker, Stawell House, Richmond (gardener, Mr. W. Bowell); J. E. Meek, Esq., Poulett Lodge, Twickenham (gardener, Mr. Bates); and Dr. Francis, who obtained the prizes in the order named with well-grown plants. Orchids were not very numerous but generally in fair condition; the chief prizes were awarded to C. Hart, Esq., Beaufort House (gardener, Mr. Reeves), Messrs. Jackson & Son, and A. E. Stearns, Esq., Radnor House, Twickenham (gardener, Mr. C. Barry).

In this tent the groups of dwarf Roses in pots from Messrs. Veitch and Son, Chelsea, and Lee & Son, Hammersmith, were extremely attractive, and were greatly admired by the numerous visitors. The General Horticultural Company staged a fine group of miscellaneous plants at one end of the tent, and Messrs. Veitch & Son an equally elegant one at the other end; Messrs. Osborn & Sons, Fulham, Mr. Kinghorn of Richmond, and H. Little, Esq., also contributed collections of plants that combined to form a very pleasing display.

In the large tent near the above were numbers of miscellaneous plants exhibited in competition for special prizes, and those offered by the Society to growers in the district. Ferns were particularly good, Mr. Barry being first with six exotic species, his collections including several healthy specimens. J. Wigan, Esq., was second, and Dr. Francis third with neat plants. Caladiums were well shown by Messrs. Wigan and Rutter, and the best Coleuses were from Lady John Chichester, Cambridge House, Twickenham, and J. Flaek, Esq., Twickenham (gardener, Mr. Sallows), both collections containing well-coloured plants. Mr. Rutter and J. Masters, Esq., Petersham (gardener, Mr. G. Logan), also staged two collections of Pelargoniums fairly well flowered. Mr. Bates had the finest single specimen plant, gaining the chief prize with a handsome example of *Allamanda Hendersoni* in excellent condition, and bearing flowers of great size and substance. The other exhibits in that tent were chiefly plants for table decoration, *Mignonette*, and a bright group from Messrs. J. Laing & Co., Forest Hill.

The fruit, table decorations, and cut flowers occupied a third tent of considerable dimensions, the stands of flowers being arranged on a long table in the centre, the fruit at each end, and the cut flowers at the sides of the tent. The fruit was abundant and generally of fine quality. Grapes were well shown by Mr. Bates, Mr. S. Nunn, Mr. Wells, Mr. Wagstaff, gardener to J. H. Elam, Esq., Isleworth, and Mr. Feist, gardener to R. Ashton, Esq., Staines. Strawberries were numerous and of excellent quality. Peaches, Nectarines, Cherries, both singly and in the collections, were all well represented. Of the cut flowers the Roses were most noteworthy, a very fine display being produced by the numerous stands. The blooms were very fresh and bright, and some were exceptionally fine. Some of the chief prizetakers were Messrs. Paul & Son, Cheshunt; Mr. D. Robin, Richmond Hill; Mr. Bates; J. Bull, Esq., Redholme, Teddington; Mr. W. Scott, Clinton Villas, South Wimbledon; Mr. G. P. Hawtreay, Aldin House, Slough; and Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston, the latter exhibitor staging two excellent first-prize collections.

Vegetables and the cottagers' productions occupied the remaining tents, and were both numerous and well shown, the vegetables being especially notable for their fresh healthy condition.

The arrangement of the Show was generally satisfactory, and considering the great number and excellence of the exhibits we regret that the pressing demands upon our columns have compelled us to report this fine Exhibition thus briefly.

THE CULTURE OF VANDA CÆRULEA AND VANDA TERES.

VANDA CÆRULEA.—This is one of the most beautiful Orchids in cultivation, with its pale lilac flowers produced in October, and lasting in beauty four or five weeks. It is considered a cool Orchid. I have tried to grow it in a cool house and was very unsuccessful; I then placed it in the East Indian house, where it commenced growing at once, producing roots from the stem and soon filling the basket. I grow the plant in an oak basket with dried sphagnum moss chopped fine, and all the dust well sifted out, and one-third of crocks well mixed with the sphagnum. I suspend the basket close to the glass under one of the ventilators in the roof of the house. When the plant has rooted into the sphagnum and is making its growth it requires abundance of water and plenty of air with a moist atmosphere, and when growth is completed very little water is needed during the winter months. The sphagnum must not be allowed to become too dry, or the plant will shrivel and lose its lower leaves.

Some years since I almost lost this Vanda, but just at the time it was at its worst I was reading Sir Joseph Hooker's "Himalayan Journal," where it was stated that *Vanda cærulea* was found growing upon a tree lying across a stream. The plant was in all its native luxuriance, with frost upon the flowers, and Sir Joseph wrote, "If those who exhibit this Orchid at Chiswick saw the plants growing in their native habitat they would not stew them at home." After reading the above I took the hint. Next morning *Vanda cærulea* was suspended under the ventilator as I have described, and there it remains. It began to grow freely in the spring, and I obtained flowers once more.

VANDA TERES.—The foliage of this Orchid is very much like a large Rush. The flowers are large, red and yellow, and are produced in June and July, and last a month in beauty. There are two varieties; one is very shy in flowering and is not worth growing, the other is a profuse bloomer. It is also one of the easiest of Orchids to grow, requiring very little attention, therefore it is a

most suitable plant for beginners in Orchid culture. I grow this species on a flat piece of cork, on which it is secured with thin copper wire. The roots soon take hold of the cork. It is grown in the East Indian house, and in four or five years it makes a fine bushy plant. I cut the tops of the plants off when they are too long, and fasten them to the bottom of the cork; by that means the plant becomes bushy. After growing in the East Indian house the time mentioned, I placed it in a house with a minimum temperature of 50° in winter, and during hard frost 45°; in the cool house it grows and flowers most profusely. When growing it should be syringed twice a day, the atmosphere of the house being kept moist. All it requires in winter is a slight sprinkling with the syringe when the sun shines.—JOHN NUNNS.

WE have received many pleasant letters during the week relative to the enlarged form in which this Journal now appears. It is gratifying to us to know that the change is so much appreciated, and we thank all our correspondents for their kind expressions of approval. Especially are we gratified by the commendatory remarks of two of our oldest horticultural contemporaries, who have spoken so kindly and generously of our endeavours to maintain a high standard of horticultural journalism.

— ON the evening of Wednesday, the 30th ult., the ROYAL BOTANIC SOCIETY'S EVENING FETE was held as usual in the Society's Gardens at Regent's Park, the exceptionally fine weather and admirable arrangements resulting in a gathering of remarkable brilliancy and success. In addition to the illuminations, which were carried out with excellent taste, there were Messrs. Carters' exhibition of annuals, Mr. Anthony Waterer's Rhododendrons, and groups of Roses from Messrs. W. Paul & Son, Waltham Cross, all of which proved very attractive. In the competition for bouquets and arrangements of flowers several exhibitors took prominent positions, among them being Messrs. Osborn and Son, Fulham; and Messrs. Henderson & Son, Maida Vale. During the evening it is stated that upwards of seven thousand visitors attended the Gardens.

— ON the occasion of the above fête the visitors enjoyed the opportunity of witnessing the flowers of *CEREUS GRANDIFLORUS*, the Night-flowering Cereus. A plant in the conservatory expanded its blooms early in the evening, and they continued in fine condition until midnight. It attracted great attention from the numerous visitors, comparatively few of whom had ever seen the flowers of this interesting species.

— THERE is now flowering and fruiting in the greenhouse at Chiswick a fine plant of *FRAGARIA INDICA*. For growing in baskets, or in pots or pans placed on pedestals, this distinct species of Strawberry is highly suitable. It is of rapid slender growth, the "runners" drooping down forming an elegant fringe of about 3 feet, studded with small bright yellow flowers and small highly coloured fruit. In its natural drooping and prolific character it resembles *Saxifraga sarmentosa*, and promises to be of considerable utility for various decorative purposes. It appears to produce flowers with fruit in various stages of development, at the same time it is likely therefore to be attractive during a long period. The fruit is of no use for dessert purposes.

— IN the same garden there is a fine display of IVY-LEAVED PELARGONIUMS, of which one of the best varieties yet raised is Belle d'Orleans. This is quite distinct from all others by its naturally upright growth, and it produces its magenta pink double flowers in the greatest profusion. With the aid of a few small

sticks the plant will form a handsome specimen, and be of great value for greenhouse and conservatory decoration. It has been certificated, and is worthy of that high mark of approval. Mons. Dubois has been similarly honoured. It has very large and fine deep pink double flowers, and a good plant cannot fail to be very effective. These varieties were raised by M. Lemoine, and there are some others of great promise under number. Several older varieties, grown in the form of loose pyramids, are also extremely attractive, and show how well adapted these plants are for conservatory decoration during the summer months.

— A CORRESPONDENT informs us that *RUBUS ODORATUS* is now one of the finest ornaments in the Cambridge Botanic Garden. It has an immense profusion of deep rose flowers, each blossom 2 inches across, and the leaves, which are extremely handsome and Vine-like, measure in some cases 10 inches across. It is of upright habit and grows with great vigour. A native of North America.

— A CORRESPONDENT writes that "it is generally considered undesirable or impracticable to TRANSPLANT ONIONS, but has been agreeably undeceived by seeing some flourishing in a gentleman's garden." In some districts it is a regular practice with cottagers to obtain surplus plants from the squire's garden when the crops are being thinned, and rely on them for their winter supply of Onions. We have seen many fine beds and crops from transplanted seedlings, and if the work is done in showery weather and the plants are not inserted too deeply they seldom fail to produce good and well-formed bulbs. If the weather is dry the roots are "puddled" in a mixture of soil and soot before planting.

— MADAME NUYTENS VERSCHAFFELT, widow of the late Jean Nuytens Verschaffelt, whose death we recently announced, intends carrying on the nursery business at Ledeborg, Ghent, with the same efficient manner that it was conducted by her lamented husband, and intends to deserve the patronage she hopes to receive from the horticultural public.

— THE appearance of SMALL FRUITS IN KENT is generally satisfactory. Raspberries are looking well, and the crops are likely to be fair notwithstanding the severe check they have experienced in some parts. Strawberries though bearing well have not such enormous crops as last year, or as a grower said, "More were spoilt on the ground last year than will be gathered this season."

— THE Corporation of Carlisle has just presented to the Royal Gardens at Kew the HERBARIUM OF BISHOP GOODENOUGH, who, having resided for some time at Ealing, obtained botanical specimens from Kew and other London gardens. He was afterwards made Bishop of Carlisle; was born in 1743, and died in 1827. The deceased Bishop's herbarium, now handed over to the national herbarium at Kew, was made during the last quarter of the last century, and contains many interesting and valuable specimens. Bishop Goodenough was at one time Treasurer of the Linnæan Society.

— IN one of the houses at Shirecliffe Hall, Sheffield, the residence of H. E. W. Watson, Esq., a good specimen of that attractive plant *TABERNÆMONTANA CORONARIA FL.-PL.* is now flowering, and Mr. Udall, the gardener, states that he finds it of considerable value for cutting purposes. It is of comparatively easy culture and flowers freely, the fine white fragrant blooms proving very acceptable wherever flowers are in demand. Like many other old plants of undoubted merit it is not so common in gardens as might be expected, although the cause of its neglect is by no means evident.

— AN esteemed correspondent has sent us a report of the LIMERICK HORTICULTURAL SHOW, which he describes as a large and good one, but the pressure on our columns is so great that

we can only find space for the following extract—The exhibits of Lords Dunraven and Clarina, Lady Massey, Mrs. Russell, Mrs. Boyd, and Mr. Bannatyne were specially noticeable, and in the several classes obtained merited distinction. The show of Roses in the private growers' class, notwithstanding the year being by no means most favourable, created great admiration from the Judges, and subsequently from the great throng of visitors. For the stand of twenty-four blooms Lord Clarina, Lady Emily, and Lady Massey deservedly received the prizes in the order named. But still more commendable, though not for competition, were the large stands of Roses, Pelargoniums, and Tuberous Begonias of Messrs. Saunders, nurserymen, Cork, which excited much admiration. The show of fruit for the season was splendid, and little less deserving were the vegetable collections.

— A LARGE bed of DELPHINIUMS in BATTERSEA PARK is just now very attractive. The plants are associated with variegated Maples, the pale and deep blue spikes of the flowers showing with great effect amongst the silvery foliage of the Acers. The employment of such stately plants as Delphiniums in the London parks is a step in the right direction, and they might with advantage be largely increased. When planted in deep rich soil they form pillars of beauty 6 to 8 feet high, and they produce a rich effect before the ordinary bedding plants are in beauty. Delphiniums are readily raised from seed, which if saved from good named varieties many beautiful forms are produced. Some of the best varieties of Foxgloves would also have a fine effect at this season in suitable positions in the parks, as the spikes would show to great advantage against a background of shrubs, as also would Hollyhocks a little later in the summer.

— IN Mr. Jowitt's eup collection of SWEET-SCENTED ROSES at the NATIONAL ROSE SHOW the following varieties were staged:—Mons. E. Y. Teas, Le Havre, Charles Lefebvre, Beauty of Waltham, Sir Garnet Wolseley, Catherine Mermet, Madame C. Crapelet, Maréchal Niel, Exposition de Brie, Sénateur Vaisse, Jean Liabaud, Marie Baumann, Souvenir d'un Ami, Alfred Colomb, La Rosière, La France, Baron de Bonstetten, Madame Bravy, Duc de Wellington, Madame Knorr, Louisa Wood, Marie Van Houtte, and two others, the names of which our reporter was unable to ascertain owing to the dense crowd surrounding the stands.

— AT the BRIGHTON HORTICULTURAL SHOW, which a correspondent describes as being a very good one, the following were the successful exhibitors in the principal Rose classes:—In the open class for forty-eight varieties the prizes went to Messrs. Piper, Mitchell & Sons, and Balchin, who all staged good blooms. In the class for twenty-four blooms Mr. Wollard, Lewes, and Rev. C. Hales, Woodmancoote, were the respective winners. For twenty-four Roses grown in Sussex the prizes were awarded to Mr. W. G. Sharpe, Birchin Bridge; Mr. Gravely, Cowfold; and the Rev. R. C. Hales. In the class for twelve blooms Mr. A. Slaughter, Steyning; Mr. Edwards, Worth; and Rev. G. Banks, Worth, were the prizetakers. Amongst the fruit the fine Muscat Grapes of T. Holman, Esq., and the James Veitch Strawberries from Mr. Rutland, Goodwood, attracted much attention.

— WE are informed that the TOMATOES at the LYNN SHOW, exhibited by Mr. S. Castle of The Vineyard, West Lynn, were a notable feature. Amongst his exhibits were bunches of Suttons' Conqueror and Osborn's Improved Red, each weighing 3 lbs. 7 ozs.; twelve separate fruit of the aggregate weight of 5 lbs. 3 ozs., and two others of 12 ozs. and 16 ozs. respectively. The Judges remarked that they were the finest they had ever seen.

— MESSRS. J. J. THOMAS & CO., wireworkers, 362, Edgware Road, desire us to state that they have opened premises for the sale of their horticultural appliances at 87, Queen Victoria Street, London.

— ZONAL PELARGONIUMS.—I am endeavouring as far as possible to form a complete list of all Zonal Pelargoniums now in culture. Will you permit me through the medium of your columns to ask all nurserymen who feel disposed to assist me to send their catalogues to me as soon as possible?—C. C. EWBANK, *The Vicarage, Langford, Biggleswade.*

THE OXFORD ROSE SOCIETY'S SHOW.

ON Tuesday last the twenty-ninth annual Exhibition of Roses of this Society was held in the beautifully picturesque grounds of Headington Hill Park, a charming position for a flower show, for which the Society is indebted to the kindness of George Herbert Morrell, Esq. The exhibits of Roses were not quite so numerous as usual, and in consequence the two large tents devoted to them were not nearly filled, several of the stages being comparatively bare. It is to be regretted that the Society has reduced the value of the prizes, for when these were of a more liberal character the Exhibition was not only extensive, but the collection could be very favourably compared with those seen at the more pretentious London shows or elsewhere. After nearly thirty years' experience the Society must be aware that the only way to induce exhibitors to come forward freely is to offer substantial prizes, and no doubt were the original system returned to the results would be equally satisfactory.

Although, as we have indicated, the entries were not quite so numerous as could be desired, yet there was some compensation for this deficiency in the general good quality of the blooms. Several handsome collections were staged containing blooms of great substance, fair size, symmetrical form, and bright clear colours; indeed, in the latter respect, taking the average of the blooms, they have been scarcely excelled at any Show this season. The weather unfortunately proved most unfavourable, rain falling frequently during the afternoon; notwithstanding, however, a large company of visitors assembled, being doubtlessly as much attracted by the opportunity of a promenade in Headington Park as by the Show itself. All the arrangements were quite satisfactory, and reflect much credit upon Mr. Greenaway, the Secretary.

Taking the open classes first, the principal one was that for forty-eight triplets, only two exhibitors entering in competition. The premier position was accorded to Messrs. Cranston & Co., Hereford, for four boxes of handsome blooms that were scarcely inferior to their seventy-two at the Crystal Palace; indeed some of the varieties were even better represented. The second prize was obtained by Mr. Charles Turner, The Royal Nurseries, Slough, with blooms that were chiefly inferior to the others in substance and size, but they were very neat and fresh. Louis Van Houtte, Beauty of Waltham (good), Devienne Lamy, La France, and Dr. Andry were the best in quality. For forty-eight single trusses Messrs. Cranston & Co. were again first with a similarly handsome collection, including fine examples of Duchesse de Vallombrosa (neat), Mons. E. Y. Teas, Horace Vernet, Le Havre, Marie Baumann, and John Stuart Mill. Mr. Turner followed with the only other collection in the class, staging neat and fresh examples of well-selected varieties. The best thirty-six single trusses were from Messrs. Cranston, who thus carried off the three chief prizes in the open classes, the quality of the blooms being similar to that distinguishing the other exhibits of that firm. Mr. George Prince, Oxford, was a good second with compact brightly coloured blooms, Mr. Charles Turner taking the third place with fair specimens. In the class for twelve blooms of a Hybrid Perpetual Messrs. Cranston were first with Lord Macaulay, excellent colour; and Mr. G. Prince second with good examples of Duchesse de Vallombrosa. Mr. G. Prince staged the best twelve Teas or Noisettes, followed by Messrs. Cranston and Mr. John Mattock, Bath Nurseries, Headington. Two collections of Mr. Bennett's new pedigree Roses were staged, the first prize being secured by Mr. George Prince with fair examples of the Honourable George Bancroft, Duchess of Connaught, Jean Sisley, Duke of Connaught, Beauty of Stapleford, and Pearl. The second prize was obtained by Mr. John Tranter, Upper Assenden, Henley-on-Thames, with Duchess of Westminster, Beauty of Stapleford, Viscountess Falmouth, Duchess of Connaught, and the Hon. George Bancroft, small but fresh.

In the open classes for amateurs some good collections of blooms were shown. The finest collection of thirty-six single trusses was staged by Mr. C. M. Davies, Grammar School, Aynhoe, Banbury. His blooms were exceptionally fine and fresh, and the varieties well chosen. George P. Hawtreay, Esq., Aldin House, Slough, followed with a collection of great merit. For twenty-four single trusses J. T. Strange, Esq., Aldermaston, Berks, the Rev. E. L. Fellowes, and Mr. C. M. Davies carried off the prizes with excellent blooms in fine condition. For twelve Teas or Noisettes Mr. G. P. Hawtreay was an excellent first, followed by Mr. C. M. Davies and the Rev. E. L. Fellowes, all staging fair specimens.

The most important amateur class was that for twenty-four varieties, single trusses. The chief position was awarded to the Rev. C. Eddy for admirable blooms of good substance and colour, Marie Baumann being particularly fine. Mr. William Freeman closely followed the Rev. E. Renwarne Wellings, Stamford Vicarage, Farringdon, Berks, and Mr. Alfred Evans, Marston, Oxford. For eighteen varieties Mr. Davies easily obtained the chief award with good and

fresh blooms. Mr. J. Bradley, Christchurch College, Oxford, was second with a neat collection, the two remaining prizes being secured by Mr. J. Freeman and Mr. J. Tranter. Six entries. Mr. A. Evans had the best twelve single trusses, followed by Mr. J. Wheeler, the Rev. E. L. Fellowes, Mr. Freeman, Mr. A. Callcutt, and Mr. H. Poulter, Oxford. For six trusses of one variety there were seven entries, the prizes being obtained by the Rev. E. Renwarne Wellings, Stamford Vicarage, Farringdon, Berks, first with La France, very fine; Mr. C. Callcutt, Holywell Street, Oxford, second with Louis Van Houtte, fair; Mr. W. T. Barnes, Cowley Road, Oxford, third with Marquise de Castellane; and the Rev. E. L. Fellowes, Wimpole Rectory, Royston, Cambridgeshire, fourth with Baronne de Rothschild. For six triplets Mr. Callcutt and Mr. Henry Poulter, George Street, Oxford, were the prizetakers with fair examples. The best twelve triplets were from the Rev. C. Eddy, Bramley Rectory, Basingstoke, who staged a very neat fresh collection, including good blooms of Duke of Edinburgh and Marquise de Castellane. The Rev. E. L. Fellowes was a close second, the Rev. E. Renwarne Wellings third, and Mr. W. Freeman, Queen Street, Oxford, fourth, there being five entries. Six single trusses were well shown by Mr. F. Harris, Walton Crescent, Oxford; Mr. Way, Jesus College; Mr. F. Collins, and Mr. W. Harris, all of Oxford, who obtained the prizes in the order named. The prizes for six Teas or Noisettes were obtained by Mr. Alfred Evans, Marston, Oxon; Mr. J. Wheeler, Kingston Road, Oxford; and Mr. J. Tranter with small blooms.

Strawberries were shown by Mr. G. Prince, Mr. C. Callcutt, Mr. E. Collins, and Mr. C. Taylor, who gained the prizes in the order named with fine fruits of President and James Veitch. Collections of Roses were also exhibited by Messrs. Cranston & Co. and Mr. George Prince, not for competition.

PRIMROSES AND POLYANTHUS.

THE POLYANTHUS.—Having shown, I hope satisfactorily, that the Primrose, the Cowslip, and the Oxlip are quite distinct from one another, I shall now proceed to an account of the most important of the varieties which have emanated from them, and which has been called the Polyanthus.

Like many other plants that are subjected to cultivation, the Primrose, the Cowslip, and the Oxlip sport into various forms and colours widely different from those of the wild types when grown in gardens or raised from seeds of cultivated plants, and the Polyanthus is one of them. It is supposed by some to have originated from the Oxlip. There is, however, no good ground for this belief. I have no doubt that the form which we call Polyanthus has originated from all three. After considerable experience in raising large numbers of seedlings annually I am convinced that the Polyanthus comes as much from the Primrose as from the Cowslip or Oxlip, although from its blooming in the form of an umbellate scape it may be supposed that it comes from the two latter. These seedlings when they bloom produce all the three normal forms, and there are frequently many of the Cowslip while there are few of the Primrose and Oxlip.

In speaking of the Polyanthus it must be borne in mind that I am alluding to the border Polyanthus in any remarks I am about to make. I have not had any experience with that form of the flower which is called the florists' or laced Polyanthus, yet I have no doubt that its origin is the same as that of the border varieties. There are therefore two distinct sections of the Polyanthus, one represented by the florists' or laced Polyanthus, and the other by the border flowers, or such as are grown for garden decoration.

The laced Polyanthus is a plant of comparatively modern origin. I can find no account of it in the works of the old florists of the seventeenth century, nor even in those of the early part of the eighteenth. The early editions of Miller's Dictionary make no mention of them, nor does Bradley appear to have known them, though he was a constant visitor among the nursery gardens of London in his time. In the last edition of the Dictionary edited by himself Miller speaks of the Polyanthus having been much improved during the last fifty years; but this improvement, I suspect, refers to the border varieties, and not to the prize flower of the florists. It was not till towards the end of the last century, when a standard of merit was set up by the Lancashire florists, that the characteristics of a prize Polyanthus were fully set forth, and a strain selected in accordance with this standard, which has remained distinct to the present time. The most distinguishing character of the prize Polyanthus is the smooth laced edge of the corolla, and hence they are called laced Polyanthuses.

Of the border Polyanthus there are two distinct forms which were recognised by the old florists, and which are equally well marked now as they were long ago. These are the Primrose Polyanthus and the Cowslip Polyanthus. I herewith furnish illustrations representing both of these; fig. 6 (page 25) being that which has the Primrose for its original, and fig. 8 (page 31) that which comes from the Cowslip. On referring to these it will be seen that the Primrose Polyanthus has the calyx tubular with long sharp teeth, and

as long as the tube of the corolla. The leaves are winged to the base of their footstalks. In the Cowslip form the calyx-tube is wide and inflated, with blunt teeth, and much shorter than the tube of the corolla. The blade of the leaf terminates rather abruptly, and the footstalk is hardly winged. In those that have the Primrose form there are frequently a number of single-flowered stalks issuing from among the leaves, as well as those flowers which are borne on a scapigerous umbel; whereas in the true Cowslip or Oxlip form the flowers are always in an erect umbel

on a tall scape, which is sometimes very stout, and which arises from a rosette of leaves. The laced Polyanthus of the florists is no doubt also derived from the Cowslip or the Oxlip, and not from the Primrose.

In discussing the subject of Primroses and Polyanthus in the pages of the Journal one correspondent questioned the accuracy of the statement of another that some Polyanthus sometimes become Primroses. I can verify that fact, and that some Primroses change to the Polyanthus form of flowering. These, however, all

Fig. 8.—COWSLIP POLYANTHUS. (See page 30.)

belong to the section which I have already referred to of Primrose Polyanthus. There is a very good instance of this to be met with in a Primrose which was raised a few years ago called "*auriculæ-flora*." This is a Primrose early in the season, but after a time it throws up a scape with several flowers in a small umbel, so that it is not a true Primrose. A double variety which I have grown for many years under the name of "*lilacina plena*," but which has appeared lately as a new variety under the name of "*marginata plena*," frequently assumes the Polyanthus form later in the

season, though it has all the appearance of a double violet Primrose on its first blooming. I have also many more that disport themselves after this fashion, but I do not think an instance can be found of the florists' stage Polyanthus ever assuming the habit of a Primrose or any other Polyanthus which has for its ancestor a Cowslip or an Oxlip.—PHILANTHOS.

HARDY FLOWERS.—In answer to the letters that appear in the Journal to-day with reference to my article on hardy flowers

on page 468 of your last volume, I wish to say that the article was written some considerable time before it was published, and that now the appearance of my beds is as gay as then it was gloomy. My Delphiniums, Potentillas, English Iris, Summer Phlox, White Rockets, Sweet Williams, Antirrhinums, and Roses leave but little to be desired.—WYLD SAVAGE.

FARNINGHAM HORTICULTURAL SOCIETY.

ON Wednesday the 30th ult. this Society held its annual Exhibition of plants and Roses, the weather proving much more favourable than on the same occasion last year. One of the chief objects of this Society is to encourage the culture of Roses, and in consequence a large proportion of the classes was devoted to these flowers, the result being a very fair display. Provision was also made for the exhibition of stove and greenhouse plants, but the entries were not very numerous, and with the exception of a few groups, and the collections contributed by several nurserymen, miscellaneous plants were not very strongly represented. Fruit and vegetables were well shown by a few exhibitors, the produce staged being fairly creditable examples of culture.

The chief class for Roses was the open one for forty-eight varieties, and in that the prizetakers were Mr. B. R. Cant, Colchester, and Messrs. Bunyard & Sons, Maidstone, who were placed first and second respectively with collections of neat blooms, the premier flowers chiefly excelling the others in freshness and substance. Mr. Cant also staged the best twelve Teas and Noisettes, all blooms of good form; Maréchal Niel and Devoniensis were especially notable. Messrs. Bunyard & Sons again followed very closely, *Perle des Jardins* being one of their finest blooms. In the amateurs' class for twenty-four varieties the winner of the first prize and the silver medal of the National Rose Society was S. Hall, Esq., South Darent, who exhibited a very neat collection of blooms, Dr. Andry, Sultan of Zanzibar, and Star of Waltham being particularly fine. Dr. Ashurst followed with blooms of average merit. Neat collections of twelve and six varieties were staged by Dr. Tucker of Farningham and F. Burnside, Esq., Farningham, who respectively secured the premier prizes in each class, being followed by Mr. A. Mason, Farningham, and Dr. Ashurst. In another class for twelve, confined to subscribers living within a radius of six miles of Farningham, the Rev. J. M. Fuller, Bexley, Kent, gained the chief award with fresh blooms of good colour; W. Tristram, Esq., St. Margaret's, and J. Honychurch, Esq., Springwood, Dartford (gardener, Mr. A. Purvis), following with good examples of well-selected varieties. Several other classes were devoted to Roses, the principal exhibitors being F. Warde, Esq., West Farleigh, Maidstone; Mr. J. Wakeley, and Mr. W. H. Wakeley, Rainham, Kent; Wm. Spottiswoode, Esq., Sevenoaks (gardener, Mr. J. Bolton); and F. F. Burnaby Atkins, Esq., Halstead Place.

Stove and greenhouse plants were exhibited by Mr. Bolton and H. B. Mildmay, Esq., Shoreham (gardener, Mr. J. Bart), who received the two prizes of healthy specimens. Fruit was also well shown by Mr. Bart and Mr. Bolton, who carried off most of the prizes. Among the miscellaneous collection a handsome group of Coleuses from Mr. H. Cannell, Swanley, was greatly admired; Mr. Cattell, Westerham, also contributing a group of plants.

The Exhibition was held in an open piece of ground near the Lion Hotel, and was well attended during the afternoon, the arrangements giving great satisfaction.

DOUBLE PYRETHRUMS.

I IN common with many other readers of "our Journal" was much interested in the article on the culture of double Pyrethrums by Mr. Wright. It may be seen by the remarks of Mr. Wolley Dod a fortnight ago, that the plants are uncertain and whimsical; and I have known several failures even with careful cultivators, of which I believe slugs are not the entire cause. I have seen roots get knotted or cankered. Do these plants object to lime, or lime and soot? I have fancied so. Will Mr. Wright say when the cuttings should be made, and whether only flower shoots can be used for cuttings?—S. S.

I AM greatly obliged to Mr. Wolley Dod for his important note on page 489 of the last volume. The attacks of slugs under ground I had never observed, for the reason, I presume, that previous to surface-dressing the beds in autumn I removed a little soil from the plants and filled in the space with small cinders. This was not done to preserve them from slugs, but to enable the winter moisture—heavy rains and snow—to pass away freely and prevent any decay of the crowns. I omitted to state this practice, which also, no doubt preserved the plants from slugs. I have adopted the same practice with Delphiniums and Hollyhocks with the best results. Without some such aid all the plants named canker in some soils. It is quite true that all soils suitable for Pyrethrums will not grow Carnations, but I shall be surprised to learn that soils which will grow Carnations well will not also grow Pyrethrums.

Cuttings are struck precisely the same as Phloxes. The growths

when 3 or 4 inches long are thinned-out and made into cuttings, which are inserted in sand in gentle heat. These growths can generally be well spared, and those remaining produce finer flowers. Each cutting if it is not stopped produces one flower the same season, and also forms growth at the base for another year's blooms; it is advisable, however, to sacrifice a small flower and make a strong plant. The cuttings must not remain in heat a day after they commence rooting.—J. WRIGHT.

CANTERBURY ROSE SHOW.

OF all the exhibitions of the Rose which it is my happiness to attend in the course of the brief but busy season in which they take place there is none that has a deeper interest for me than that which is held in this old cathedral city, associated as it is with my boyish days, where, ere the cares and anxieties of the battle of life came upon me, so many happy days have been spent with dear relatives—now, alas! gone. I cannot but feel an interest in it, although it did seem strange that as I walked through the streets there were none of those whom I formerly knew to welcome me; for as showing the manner in which families get scattered in these days on the face of the earth, for the first time for upwards of three hundred years there is not one of my name left in the old city, which has been its English home for that period. Well, let that pass; we come to the present. I have watched the growth of this new Society. I was enabled briefly to chronicle its first Exhibition; and now what can I say but that all interested in the Society must feel gratified at the rapidity with which it has risen in public favour, and the success which has attended this, its second Show. A Society which can attract to it, not only the growers in its own neighbourhood, but such men as Cant of Colchester, Mitchell of Piltown, and Prince of Oxford, must occupy no second-rate position, and in truth one rarely sees a better-filled room or more creditable flowers than were shown on this occasion.

The nurserymen's class was well represented, and the boxes of Tea Roses especially were so excellent and so nearly equal as to give considerable trouble to the Judges. The first prize was ultimately awarded to Mr. Prince of Oxford, who had a grand box, containing amongst others splendid blooms of Anna Ollivier, Madame Bravy, and Souvenir d'Elise; but I think the amateurs may well be proud of the position they occupied, the quality of their flowers being very excellent. Mr. W. Mount took the first prize for eighteen with a very even and well-flowered collection, notably amongst them a grand and large bloom of Mons. E. Y. Teas, Maréchal Niel, Penelope Mayo (very good), Marie Rady, Madame Victor Verdier, and Alfred Colomb. The Rev. H. B. Biron's box of twelve was one of the most perfect stands I have ever seen, and when I call to mind the few Roses that he has to cut from and the losses he has had I cannot but say it does him infinite credit. They were Marie Rady (grand), Marie Baumann (a splendid bloom), La France, Reynolds Hole, Marquise de Castellane, Royal Standard as good as I have ever seen it, Mlle. Eugénie Verdier, Le Havre (a truly grand bloom, obtaining the bronze medal of the National Rose Society for the best Rose in the Show), Naomi, a flower which no one seemed to know. It is a large dark flower with shell-like petals, something in the way of Reynolds Hole, but more regular in form; Duke of Edinburgh, Etienne Levet, and Annie Wood. This box not only obtained the first prize for the best box of twelve, but also the silver medal of the National Rose Society for the best box of any number in the Show, while Mr. Biron obtained the silver cup given by the city Members for the exhibitor who had obtained the highest number of marks. Mr. George Mount of Harbledon obtained the first prize for six varieties, for Alfred Colomb, Jules Margottin, Lord Raglan, Duke of Edinburgh, Souvenir de la Malmaison, and Charles Lefebvre, all very good blooms. Mr. J. Wakeley of Rainham obtained the first prize in Teas and Noisettes for excellent blooms of Madame Margottin, Comtesse de Nadaillac, *Perle de Lyon*, Souvenir d'un Ami, La Boule d'Or, Jean Ducher, Céline Forestier, Céline Berthold, Maréchal Niel, *Perle des Jardins*, and Madame Falcot. Mr. William Mount was first in six Teas with very fine blooms of Hippolyte Jamain, Souvenir d'Elise, Bouquet d'Or, Comtesse de Nadaillac (very lovely), Rêve d'Or, and Souvenir d'un Ami. Mr. Wakeley was first for six trebles, showing good blooms of Madame Lacharme, Duke of Edinburgh, Nardy Frères, Duke of Wellington, Marquise de Castellane, and Duke of Connaught. For the best six of one variety Mr. Biron was first with La France in capital condition. There was a very sharp competition for the prizes offered by Mr. B. R. Cant of Colchester, the first being taken by Mr. Wakeley.

The table decorations were not quite up to the mark, having the too common fault of being too full. There is doubtless a great temptation when good flowers are to be had to crowd them in, but it can never be too strongly impressed on all those who have to arrange table decorations or flowers in any way, that lightness and elegance are more to be desired than quantity of material or gorgeousness of colouring.

The room which, as I have before said, is admirably adapted for the purpose, being lofty and lighted from the roof, was quite filled with Roses. The arrangements were excellent, and I am sure all lovers of the Rose who rejoice to see a taste for it spreading widely are much indebted to the able Secretaries, the Rev. H. B. Biron and Mr. W. Mount, for the zeal and courtesy with which they brought

to a successful issue this second Exhibition of the Canterbury and East Kent Rose Society.—D., Deal.

A NEW SOCKET VALVE.

IN our report of the great summer Show of the Royal Horticultural Society we briefly referred to a new throttle valve invented by the Meadow Foundry Company (Limited) of Mansfield, and for which the manufacturers were awarded a silver medal. This valve is different from all others that we have seen, inasmuch as the socket in which it is fixed is moveable (fig. 9), and only needs to be inserted in the pipe and screwed down (fig. 10), and it is firm, safe, and complete. This new valve takes up no more room

Fig. 9.

Fig. 10.

than an ordinary valve, and can when necessary be taken to pieces, cleared of the cause of any stoppage, and replaced in a few minutes by the stoker or gardener; and by keeping a spare valve plate and seating in stock a damaged plate through accident can be replaced as simply. The high mark of approval which the valve received at the Show referred to is sufficient recommendation of its merits, and after examining the valve carefully we consider it worthy of the recognition it received by the Judges.

TUNBRIDGE WELLS HORTICULTURAL SOCIETY.

JULY 2ND.

ALTHOUGH the twenty-fourth annual Exhibition was not the largest ever held in the town, the surroundings of which are so beautiful, yet it was of undeniable excellence. Specimen plants were very good, fine-foliaged plants fair, Ferns excellent, while Fuchsias, Achimenes, and Begonias were better than we have seen for a very long time. Groups of plants for effect had a tent to themselves, and were attractive; and another large marquee was devoted to fruit, which was of great merit. Roses formed an attractive display, table decorations and collections of wild flowers splendid, bouquets tasteful, and vegetables very good.

PLANTS.—We are only able to notice the exhibits in the principal classes and enumerate the chief prizetakers. Mr. Balchin, Silverwood Conservatory, Western Road, Brighton, staged admirably in several classes, and secured first prizes in the open class for eight specimen plants in bloom, for eight fine-foliaged plants, for six Ericas, for eight Ferns, for bouquets, besides some minor prizes. Mr. Bolton, gardener to W. Spottiswoode, Esq., Coombe Bank, Sevenoaks; Mr. Pope, gardener to J. J. Barran, Esq., Holmwood, Tunbridge Wells; Mr. Johnstone, gardener to the Marchioness of Camden, Bayham Abbey; and Mr. Peed, Norwood, were also highly successful, and staged plants of great merit in the leading classes. A few of Mr. Balchin's noteworthy plants were *Statice imbricata*, 7 feet over, and Ferns; Mr. Barran's *Crotons* and *Kalosanthes*; Mr. Bolton's *Clerodendron fallax*, with a dozen fine heads, and *Maranta vittata*, fresh and fine; and Mr. Peed's *Ixora Prince of Orange*.

In the open class for six Fuchsias Mr. Turner, gardener to F. R. Le Lachaer, Esq., The Wilderness, Pembury Road, Tunbridge Wells; Mr. Earley, gardener to G. A. Brittain, Esq., Ferndale House; and Mr. Shrivess, gardener to the Corporation of Brighton, secured the prizes in the order named with healthy, well furnished, admirably bloomed pyramids, 5 to 6 feet high, and 3 feet in diameter at the base. The "Try-me-O" of Mr. Turner would have gladdened the heart of a Cannell. In Achimenes Mr. Scammell, gardener to Charles Reilly, Esq., Nevill Park; Mr. Bashford, gardener to F. Douglas, Esq., Chilton House; and Mr. Wilkins, gardener to Mrs. Williams, Shirley Hall, Langton, were the respective winners with fresh healthy examples 2 feet across, covered with fine flowers. The last-named exhibitor was first in the Zonal Pelargonium classes with good plants. Mr. Shoebridge, gardener to W. Edwards, Esq., Fairbank, Sandrock Road; and Mr. Allen, gardener to G. Hambro Field, Esq., Ashurst Road, Bolton, securing the prizes in the Show and Fancy classes. Remarkably fine pans of *Selaginellas* were staged by Messrs. Scammell, Bashford, and Mayer (gardener to Mrs. Foster, Boyne House), and Mr. Earley.

For groups of plants the prizes went to Messrs. Bolton, Bashford, Pope, Turner, Scammell, and Earley. Though all possessed merit

they were rather too smooth and level. Mr. Pope's (third) was the most tasteful, but required more flowers. One (very properly passed) was a mere floral toy, like a collection that somewhat strangely was awarded the chief prize at the great summer Show at Kensington. Those groups were in squares, but would have had a more pleasing effect in half-circles.

FRUIT.—This was of great excellence. The collections were exceedingly smart—perhaps too smart—as arranged on square trays covered with moss and lichens margined with foliage and sprinkled with flowers. A dessert cannot be placed on the table in this form, and the ornamental adjuncts are calculated to detract attention from the real merit of the fruit, yet the prizes were rightly awarded to Mr. Hopgood, gardener to Sir Julian Goldsmid, Bart., Summerhill, the noteworthy dish being a fine bunch of the Duke of Buccleuch Grape; Mr. Henderson, gardener to F. Deacon, Esq., Mabledon Park, a close second; Mr. Fennell, gardener to E. Cazalet, Esq., Fairlawn Park; and Mr. Bashford, all of whom staged excellent produce. Splendid Pine Apples were staged by Mr. Scammell; Mr. Hopkins, gardener to R. Thornton, Esq.; Mr. Harris, gardener to O. A. Smith, Esq., Hammerwood, East Grinstead, also had good fruit. Mr. Johnstone was placed first for three varieties of Grapes, Duke of Buccleuch being excellent; Mr. Bolton and Mr. Allan having the remaining prizes with good and well-finished bunches. For Black Hamburgs the prizes went to Mr. Reeks, gardener to R. Watson Smith, Esq., Woodhurst Castle, Mr. Henderson and Mr. Hopwood, who all staged superior fruit in a very fine class. In the class for white Grapes Mr. Blundell, gardener to F. Holtman, Esq., East Hatherley, was first with good Muscats, but not perfectly ripe; Mr. Johnstone second with Buckland Sweetwater, very fine but overripe; Mr. Bolton third with good Foster's Seedling, and Mr. Barnes fourth with excellent examples of Golden Champion—a most difficult class to judge. Peaches were very fine, Mr. Fennell winning with a splendid dish of Noblesse; he was followed closely by Mr. Johnstone and Mr. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, who had the remaining prizes. Nectarines were fine. Mr. Allan was first with such a grand dish of Elruge as is seldom seen; Mr. Goldsmith, gardener to Mrs. Lambert, Sandhills, Bletchingley, and Mr. Bashford, following with excellent fruit. Strawberries were splendid. Mr. Goldsmith was first with a remarkable dish of James Veitch, the thirty fruits weighing 3 lbs. 6 ozs.; he also staged a plant of the same variety in a pot with forty to fifty fruit, several of which exceeded an ounce in weight. The second prize in the class was won by Mr. Fennell, and third by Mr. Holliday, gardener to J. Norris, Esq., Castle Hill, Bletchingley, both with superior dishes of Sir J. Paxton.

ROSES AND CUT FLOWERS.—Mr. Piper, Uckfield, was first in the classes for forty-eight single Roses and twenty-four triplets, Messrs. Mitchell & Sons being second in both classes with good stands. For twelve and twenty-four blooms J. B. Haywood, Esq. (Mr. Ridout, gardener), had the chief prizes with grand blooms, the latter stand not being equalled at the National Rose Show. Mr. F. Warde, West Farleigh, and Mr. Goldsmith had the remaining prizes in these classes with good stands. Messrs. Wood & Son, Maresfield, staged an excellent collection of Roses not for competition. In the class for eighteen varieties of cut flowers Messrs. Johnstone, Bolton, and Hopkins secured the prizes with splendid stands.

TABLE DECORATIONS AND WILD FLOWERS.—The stands furnished with exotic flowers were tasteful, but those containing wild flowers and Grasses were of extraordinary merit. We never saw them equalled, and the winners—Miss Parkhurst, Quarry Hill, Miss Staples, The Gardens, Chipstead Place, Sevenoaks, and Miss Satchell—have our congratulations. The association of Poppies, Ox-eye Daisies, Cornflowers, wild pink Roses, and Water Lilies with Grasses was most elegant. We have a high meed of praise, too, for the exhibitors of collections of wild flowers, of which we cannot speak too approvingly. The first-prize collection of Miss Isabella Cox of Redleaf was of exceptional merit; the flowers, nearly one hundred, were arranged tier above tier, with the botanical and popular names of each flower neatly printed on small cards, the effect being very complete. Miss Ware's (of Frant) collection contained perhaps still more varieties; and most meritorious were the stands from Mr. Dixon, gardener to Captain Taylor, Glenleigh, Hastings, and Mr. Allan, Ashurst Park, who had the remaining prizes.

The Show was held in the extensive and attractive grounds of Bishop's Down Grove, Spa, and was largely attended by a fashionable company. To Mr. Loof, who has been the Society's efficient Secretary since its formation, we are indebted for much courtesy during our visit to this excellent Show.

THE PRIMROSE AND POLYANTHUS.—I have been greatly interested in the discussion on the origin of the Primrose, Cowslip, and Polyanthus, as I have been collecting some of the best seedling Polyanthus with the idea of improving them by cross-breeding and selection. Two years ago I met with a blue, or rather a lilac-blue, Polyanthus, and have now four seedlings from it. This year I divided the plant, and now find one of the plants is producing seed (fertilised) on single stems like the Primrose, the other is producing seed on a stem the same as the Polyanthus.

I find no difficulty in getting seed from the thrum-eyed fertilised with the pin-eyed or *vice versa*.—X.

BROCKHAM ROSE SHOW.

IN one of the loveliest spots in that very lovely vale, watered by the Mole, stretching from Redhill to Guildford, and within about two miles of the town of Dorking, the members of this Society or Club held their meeting on one of those bright and sunshiny days which form so striking a contrast to those we experienced last year. The Society has a peculiar constitution: its members are limited to a certain number, its exhibitions are held in private grounds, to which, however, the public is admitted, and thus the outside world enjoys not merely the sight of the Roses, but a stroll through beautiful and well-kept grounds. The Rookery, the residence of Mr. Fullar, was this year offered to the Society, and a more fitting place could hardly be imagined. The house is situated at the foot of a high hill covered with fine Beech trees, and just below it there is a pretty lake surrounded on all sides with fine foliage and well-kept lawns. Here, then, at the border of the lake was pitched the tent of the Society, and here its exhibits were displayed, and on the lovely bright day nothing could be more delightful. Different, doubtless, it would have been had the weather been wet or stormy, but both exhibitors and visitors thankfully received the welcome weather.

The exhibits are confined to amateur members of the Club, and exceedingly well did they maintain their position, for some excellent stands were displayed by the Rev. Alan Cheales, Lady Lawrence; Messrs. Stone, Wollaston, Horne, and others. The best box of twenty-four was that exhibited by the Rev. Alan Cheales, who had fine blooms of Madame Thérèse Levet, Charles Lefebvre, La France, Marquise de Castellane, Marie Baumann, Magna Charta, Baronne de Rothschild, Comtesse d'Oxford, Sultan of Zanzibar, Annie Laxton, Duke of Edinburgh, Dupuy Jamain, Cheshunt Hybrid, Marie Rady, Fisher Holmes, Boule d'Or, Pierre Notting, &c. This stand, although perhaps not quite equal in quality to that Mr. Cheales exhibited at Reigate, contained some very fine blooms. Mr. Wollaston was second with a nearly equal stand containing the finest Rose in the Show—a magnificent bloom of A. K. Williams. Not only was it this, but it was the finest Rose I have seen this year; and I write this after having seen the National Rose Show at the Crystal Palace, where the same variety as shown in Mr. Baker's stand took the medal offered by Mons. Lenaerts of Antwerp. It is unquestionably a grand flower, imbricated like a Camellia, and of a brilliant scarlet, recalling *Senateur Vaise* at its best, but even brighter than that variety. The twelve exhibited by G. Stone, Esq., were very fine, and comprised Madame Lacharme, Général Jacqueminot, Baronne de Rothschild, Marie Baumann, John Hopper, Thomas Mills, very bright; Mous. Noman, Cheshunt Hybrid, Fisher Holmes, Madame Clemence Joigneaux, Pierre Notting, and Miss Hassard.

A very pretty class here is that for four triplets. Mr. Stone obtained first prize with Baronne de Rothschild, Marie Baumann, Général Jacqueminot, and Pierre Notting. There were several boxes of Teas shown. Some very pretty stands of flowers were set up, and the Treasurer, Captain Lang, offered prizes for wreaths for ladies' shoulders as they are worn now. The buttonhole bouquets were very pretty. The first prize was won by C. E. Cuthill, Esq. All the arrangements were admirably carried out by the Secretary, the Rev. Alan Cheales, and the Exhibition altogether was both interesting and good.—D., Deal.

EXHIBITING VARIEGATED PELARGONIUMS.—An exhibitor shows two silver variegated, two gold variegated, and two bicolors, in a class for "six Pelargoniums, variegated varieties." The judges disqualify the exhibit on the ground that the bicolors do not come under the heading of variegated Pelargoniums. Is the decision of the judges a correct one?—DUNCAN & SON, *Christchurch, New Zealand*.

[There are gold and silver tricolor and gold and silver bicolor Pelargoniums, and all are equally eligible to compete in a class of "variegated varieties."—EDS.]

FRUIT HOUSES.

Peaches and Nectarines.—When the fruit has been all gathered in the earliest house the trees must not be neglected, especially as regards the supply of water to the inside borders, and if the trees are enfeebled afford weak liquid manure, which will assist them greatly. The bearing wood of the season must be removed to allow of free access to light and air, and the beneficial action of water from syringe or

engine, which must be effectively supplied daily to cleanse the foliage and keep it free from red spider. If the roof lights are moveable remove them; if not, ventilate to the fullest extent. Houses in which the fruit is ripening should be freely ventilated, fire heat not being necessary except during unusually cold, wet, sunless weather. If the fruit ripens too rapidly it may be retarded by shading with some light material during the hottest part of the day, but do not resort to this unless absolutely necessary to secure fruit for a special purpose or to continue the succession. In later succession houses, where the fruit is about taking the second swelling after stoning, copious supplies of water will be necessary, and liquid manure if the trees are weakly or carrying a heavy crop; water, clear and soft, being applied forcibly by a syringe or engine to keep red spider in check. Ventilate in favourable weather, and reduce the ventilation early in the afternoon if it be desired to accelerate the ripening of the fruit, otherwise admit air freely at all times in favourable weather. Keep the shoots tied-in as they advance, thinning out superfluous growth.

FLOWER GARDEN.

Ply the hoe and rake frequently in favourable weather, for under no circumstances must weeds be allowed to increase. Trim the edges of walks or beds with the edging shears so as to render the garden neat and clean, rolling gravel walks after rain so as to keep the surface smooth and firm. Continue to peg all kinds of trailing plants as they advance in growth, and encourage them in every way to fill the beds as quickly as possible. Beds that have been mulched over as advised will now require but little attention as regards weeding and watering, as much of this labour will be saved; but those not mulched should have the surface stirred occasionally to destroy weeds and lessen evaporation. Subtropical plants can scarcely receive too much water, and if the weather be warm mulch heavily with well decomposed manure, and stake and tie the plants securely as they advance in growth. Hollyhocks, Dahlias, and other plants of strong growth should be treated similarly. Alternantheras, Pyrethrums, &c., should, if the weather be dry, receive abundant supplies of water, or they will soon cease growth and fade in colour. The plants should be confined to the spaces or lines allotted to them, so that the design may be readily traced, and the clearer the design the more effective are all carpet beds. Carnations should be neatly staked before they become too forward, advancing the propagation of these and Pinks by layers and pipings, choosing an old spent hotbed on which to place the handlights to contain the latter, inserting them in sharp sandy loam, keeping well shaded from the sun, and gently sprinkling overhead occasionally so as to keep the atmosphere moist.

Propagating Roses.—Cuttings of Roses strike freely at this season, and in light soils are preferable to those on the Briar. The cuttings should be prepared from well-ripened wood, inserting them in sandy loam under handlights over a spent hotbed, shading from bright sun, keeping close, and sprinkled overhead daily until the cuttings begin to grow, when air should be admitted. Briar and other stocks will be sufficiently forward for budding, dull weather being most favourable for the operation. Choose wood that has just borne flowers, the buds being more mature than such as are obtained from sappy barren shoots, successful budding depending quite as much on selecting sound mature buds and in extracting the wood as on inserting and tying. In taking the wood from the bud be careful not to injure the bark by too sharply bending it back or bruising it in any way, or the bud is almost certain to fail.

Roses of the Hybrid Perpetual section as they go out of bloom should be shortened back a little, and every means taken, by freeing them of insects, syringings overhead, and copious supplies of water or liquid manure to the roots, to insure a free growth and consequent free autumn flowering. Such varieties as *Maréchal Niel* trained to walls should have the old wood cut out and young wood laid in, not too thickly, to replace it for next season's flowering. Look over climbers frequently, tying or nailing as required, after having regulated the growth by thinning out. If in dry borders supply water abundantly in dry weather, and keep the foliage free from insects by syringing with the garden engine or the prompt applying of an insecticide.

PLANT HOUSES.

Stove.—Many stove plants from their quick growth soon become

too large for general purposes or disfigured from employment for decoration, that it is better to propagate young plants and discard the others. The shoots of most hardwooded plants will now be in a half-ripened condition and will root freely. Such should be inserted singly in small pots, and they will produce roots quickly in a brisk moist heat, but quite as safely in a close case in the house where the plants are growing from which the cuttings are taken. Plants that strike freely in this way are Gardenias, Tabernæmontanas, Ixoras, Medinillas, Clerodendrons, Rondeletia speciosa, Bougainvilleas, Thunbergias, Hexacentris, Dipladenias, Stephanotis, Combretum, Æschynanthus, &c.

Allamandas, Dipladenias, Bougainvilleas, &c., when well managed flower continuously through the summer and autumn; but as they are of strong growth and exhaust the soil before the end of the season a surface-dressing of thoroughly decomposed manure and liberal applications of liquid manure, which will enable the plants to continue flowering right into autumn. Any choice varieties of Gloxinias may now be propagated by leaf-cuttings, which root better at this season than earlier when the leaves are soft. They should be inserted in sandy soil around the sides of the pots, keeping them near the glass and shaded from bright sun, being careful not to keep them too moist. Pot off the cuttings of Poinsettias and Euphorbia jacquiniæ-flora as soon as rooted, for the plants feel the check more keenly if this be deferred until the growth is more advanced.

Ferns.—Any plants that were not potted in spring should now receive attention, providing good drainage, and soil that will admit of the water passing freely through the soil, charcoal or sandstone being a suitable admixture to the peat. Plants with creeping rhizomes, as Davallias, Gleichenias, &c., should never be allowed to suffer from having their creeping stems injured, as they will if they are allowed to extend over the rims of the pots. Ferns must never be allowed to suffer through insufficient supplies of water, especially Gleichenias, as if ever the young fronds flag for want of moisture they become stunted, never attaining their proper size. Tree Ferns, particularly Cyatheas, when allowed to become dry at the roots are disfigured both in form and colour. Insects, especially scale, must not be allowed to increase, or the trouble of cleansing is not only great but much injury is done to the fronds in destroying it. Thrips should be kept under by fumigation.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Coleworts.—Few amateurs have realised the value of small Cabbage or Coleworts during the early part of the winter. It is not yet too late to sow a good breadth of some of the small early varieties, such as Cocoanut and Rosette Colewort. The plants will be ready to follow autumn-sown Onions, Potatoes, Turnips, Peas, Beans, and other early-maturing crops. Those that do not produce hearts will be useful as greens, and in this state large quantities are annually bunched and sent to the markets. If this practice of growing Coleworts is adopted the stems of the autumn-sown Cabbage may be cleared off, as they greatly impoverish the soil, and can be followed with either the earliest or main crop Celery.

Celery.—Advantage should be taken of dull showery weather to plant out the main crop of Celery. If the ground is unoccupied do not wait till the plants are large, as small sturdy plants take more readily to the soil, becoming well established before we usually experience very hot and dry weather. Single lines of plants in the trenches are the easiest to manage. The trenches may be 18 inches wide and about 4 feet apart. Take out the first spit of soil without the shovellings and distribute evenly on each side of the trench, then thoroughly mix a liberal quantity of well-decomposed manure with the bottom spit. If either the bottom spit of soil is stiff and very poor, or manure be scarce, throw out the shovellings, break up the bottom spit, over this thinly distribute the manure, and next a layer of soil to work in with the plants. Do not cramp the roots should there be no ball of earth attached, but lay them out flatly and cover firmly with soil. If the plants have been pricked out as previously advised place the flat balls directly on the manure and cover with soil; unless extra large sticks are required a distance of 9 inches apart will suffice.

Remove all suckers from the plants previous to planting, and the latter operation, unless dull weather prevail, is best done towards the evening. In either case well water the plants, and sprinkle them overhead frequently till established.

Other Necessary Work.—During showery weather proceed with all possible dispatch with the final transplanting of winter greens, Brussels Sprouts, Savoy, and Broccoli. Plant in drills as much as possible, the better to admit of water being freely supplied should they at any time require it. A loose soil does not suit any of them; all light soils should therefore be well trodden previous to planting. A firm rich soil is requisite for the present sowings of Lettuce; make small fortnightly sowings, and avoid transplanting as much as possible. Thin out Runner Beans where crowded. Those to be grown without stakes should be topped at the second joint, and any side shoots that follow at one joint each. Abundance of strong spikes of bloom will follow this pinching-back, and the earliest Beans are usually taken from those so treated.

GREENHOUSES AND FRAMES.

Auriculas.—Now is a good time to repot these; very early potting induces autumn blooming, which is undesirable. Shake the soil clear of the roots, shortening back the main root, and repot firmly, employing soil consisting of three parts turfy loam to one of leaf soil, with a good addition of silver sand and a few small pieces of charcoal. Single crowns give the best trusses; and pots of suitable size for the strongest plants are those 5 inches in diameter, and others in proportion, which should be clean and carefully drained, covering the crocks with very fibrous loam well beaten, and failing this with moss. Place them in a cold frame, either facing the north, or better still, on the north side of a wall. Water them in the course of four or five days, and keep them close till they have commenced to root afresh; after which more air should be given. Attend carefully to the watering, and pick off decaying leaves. Auriculas may be propagated by division when there are two or more main growths, or the strongest offsets may be taken off and either pricked out into well drained boxes or in small pots, in each instance sufficiently deep to admit of being covered with squares of glass. Use light sandy soil, water sparingly, and to prevent the plants damping off wipe the glass and give air for a short time every morning. A high temperature and dry atmosphere are very injurious to Auriculas in any stage of growth.

Azaleas.—Repotting Azaleas when performed by either careless or inexperienced persons often ends in the gradual death of the plants. The proper time to repot is when they are making fresh growth, as then the root-action is the most brisk. Large shifts should be avoided, and as a rule a pot about 2 inches larger in diameter is sufficient, the soil to consist of three parts good peat to one of good fibrous loam with a liberal addition of silver sand and a sprinkling of charcoal. If good turfy loam is unavailable use all peat. Carefully drain the quite clean pots, placing a thin layer of the roughest soil over the crocks, next a little finer soil; and when the thoroughly moist ball is in position gradually work the soil round it, ramming it down with a pottling stick at the same time, and finishing off evenly and firmly allowing about the depth of the rim of the pot to admit of watering properly. Remove the plants to the warmest part of the house shade from bright sunshine, and syringe frequently. In about three days give sufficient water to thoroughly soak the soil, and at no time after should it be allowed to become dry. Badly rooted and unhealthy plants should have all the sour soil carefully pricked off and the plants repotted into as small pots as possible. Cut or pinch back any long strong growths, as they are both injurious and disfiguring.

Mignonette.—Plants intended to be grown into specimens for blooming during the winter should not be allowed to become rootbound, but should receive an occasional small shift till they are in 9-inch or 10-inch pots, either being suitable sizes in which to flower them. Suitable soil consists of three parts turfy loam to one of well-decomposed manure, with a good sprinkling of mortar rubbish. When potting the soil cannot well be made too firm, and at no time should the plants be allowed to become dry at the roots. Place a light stake in the centre of the triplets intended for pyramids, taking up the leading shoots only, pinching out the bloom spikes as they form, and

also lightly pinch back the side shoots. Stake the single plants intended for standards; train up the leading shoot which forms after the bloom spike is pinched out only, and rub out all side shoots. They may be grown to a great height, but a height of from 18 inches to 2 feet will suit most cases. A sunny and rather sheltered spot is now the most suitable for them.

Rather closely pinch back young growing plants of Libonias, Salvias, Solanums, Veronicas, Eupatoriums, and Coronilla glauca, and when they break afresh either repot or plant them in a warm border, the soil of which is rather light. All to be lifted and potted before the arrival of frosty weather.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Pine Apple Culture (*R. Sutcliffe*).—The "Pine Apple Manual," published at our office, price 2s. 6d.

Cucumber Culture (*S. C. H.*).—"Kitchen Garden Manual," published at our office, price 4½d., post free.

Exhibiting Roses (*A. Paine*).—Two Tea Roses of different varieties should not disqualify unless the wording of the schedule forbids it specially.

Saw Machine (*J. G.*).—The makers must advertise it, or you must advertise your want. We cannot inform you.

Cactus grandiflorus (*W. B.*).—The fruit is not eaten that we are aware of, but the fruit of *C. speciosissimus* when well ripened, is good, and that of *C. triangularis* (the Strawberry Pear) very delicious when ripened in a climate suitable for developing its qualities.

Odontoglossum vexillarium (*C. C.*).—If the flowers are fertilised and seed pods form and swell, small plants would no doubt be injured if the seed was left to ripen, as the strength of the plants would be devoted to supporting the seed and might be exhausted.

Honesty (*C. M. F.*).—If the weather is fine the seed vessels become quite silvery without any assistance; if wet weather prevails the plants may be taken up when the seed is on the eve of maturity, or the stems be cut off and placed in a dry place under glass, and outdoors when the sun shines, to mature the seed and bleach the pods.

Green Fly on Celery (*Reader*).—Syringe the plants with a solution of soft soap and tobacco water, Gishurst compound, or any other approved insecticide of the strength that has so often been recommended; or after rendering the foliage moist dust the plants with tobacco powder, and the aphides will soon disappear.

Heating Pit (*K. W.*).—If you have no side lights one 4-inch pipe taken round the pit would be sufficient for maintaining a suitable temperature for the plants you name. Two 3-inch pipes and a good boiler would enable you to work the pit at an intermediate or cool stove temperature in winter if required without hard firing.

Abnormal Fuchsias (*A. O. L.*).—It is not at all unusual for small coloured incipient petals to form on the stamens, and we have seen many flowers much more marked in this respect than those you have sent to us. These freaks of Nature cannot be accounted for, but such changes are the most common in vigorously grown plants.

Calycanthus not Fragrant (*A. B.*).—There are several species of Calycanthus which are not remarkable for their fragrance, and possibly yours may be one of them. What is its specific name? They flower in early summer. Perhaps, however, you mean Chimonanthus fragrans, which is often called Calycanthus; but this flowers during the winter, from December onwards, and the flowers, though not particularly attractive, are highly fragrant.

Beetles on Conifer (*J. B.*).—Your specimen is attacked by the Pine beetle, *Hylurgus piniperda*, and will probably receive great injury unless you can adopt some means of eradicating it. In the case of a large specimen this is most difficult, and we can only suggest a good washing through a powerful engine with a solution of nicotine soap, of a strength of 3 ozs. to the gallon of water. If anyone can suggest a better remedy we should be glad to publish it.

Ants in Orchid Pot (*Inquirer*).—If the pot is thoroughly well drained, as it should be, we should place it in a tank of tepid water for a few hours. This we think would not injure the plant, while it might either drown the ants or induce them to take their departure. If very numerous they often do injury to flowers. We have seen them eat quite into the buds of Roses, and nibble off the stamens of Peach blossom in thousands.

Red Rose for Beds (*Constant Reader*).—It is not easy to select a red Rose having the habit and strength of the Gloire de Dijon, and that produces fine blooms freely and continuously. Crauston's climbing Charles Lefebvre partakes of the habit of the Rose you name, but we do not think it so useful for a bed as

the "Crimson Bedder." The old Général Jacqueminot is a most useful variety for massing, as it produces richly coloured flowers freely and for a long period.

Griselinia littoralis (*A. J. G.*).—This is a New Zealand shrub with shining coriaceous leaves and small inconspicuous flowers. It is propagated by layers in the autumn, by half-ripened shoots in sand under a handglass, and from seed. *Daphne indica* is propagated by inserting firm shoots in sand under a handglass in a close frame towards the end of summer, but more commonly by grafting on a hardy free-growing stock, such as *D. Lanreola*, in March in a close frame. *Brugmansias* are increased by inserting cuttings of half-ripe stubby shoots in sandy soil in gentle heat under a handglass, and shaded to prevent flagging. We know of no book such as you appear to require.

Mealy Bug on Vines (*One in Trouble*).—We regret being unable to inform you of the best method of destroying or keeping in check mealy bug, which has made its appearance amongst some black and white Muscat Grapes which are beginning to colour. We have been fortunate in never having had to contend with the pest under such circumstances, but will readily publish practical information on the subject from those who are in a position to supply it.

Potatoes Unhealthy (*G. R. B.*).—The plants sent, we are sorry to inform you, are in our opinion affected with the Potato disease. Its outbreak is as much a mystery to us as it is to you, and the circumstance is the more perplexing, and we fear unfathomable, since the reputed disease-resister, the Scotch Champion, was the first to be affected, and is the most injured of all your varieties. Your soil is not of a nature, and especially as you have used no manure, for inducing the disease; but more depends on the weather than the soil; and of the amount of rain you have had, with the prevailing temperature, you say nothing. We shall be glad to hear particulars on this point, and also to know if the disease is spreading.

Seedling Delphiniums (*John Cooper*).—The spikes sent are very handsome and indicate that the plants are well grown; the varieties are also good but not superior, and many of them not quite equal to the best named varieties in commerce. As you grow "a choice collection of the best named varieties," you will be quite justified in naming such of the seedlings as are quite distinct from all others in your collection, and growing them for the adornment of your garden and distributing amongst your friends; but we do not consider the flowers you have sent, beautiful as we admit them to be, possess any substantial commercial value.

Camellia Leaves Spotted (*F. E. D.*).—The cause of the evil is defective root-action, the roots not supplying sufficient nutriment to support the foliage, hence it spots at the edges, as in the leaves you have sent, and decays. As your plant was healthy before it was placed in the tub the soil used may not be suitable, the ball of the plant may have been dry when placed in the tub, or the plant may have been watered too freely afterwards, rendering the soil sour and injuring the roots. Any of these contingencies would produce the effect of which you complain. The remedy is inducing a more active state of the roots, and shading the plant from bright sun.

Ivy for Covering a House (*Vicar*).—The quickest-growing is, we think, the Irish (*Hedera canariensis*), and that we should plant. We should procure good strong plants in pots, and we have had them with shoots 6 feet long, and otherwise well furnished. They may be planted at any time. The price varies with the size of the plants. For the size named we gave 30s. per dozen, for good well-rooted plants in pots 15s. per dozen, and for small but well-rooted 9s. to 12s. Plant at once. The plants will be well established for a good growth another season.

Vines Unsatisfactory (*Subscriber*).—Although you have written fully on the subject that perplexes you, as all inquirers should when seeking information, you have yet omitted to state one or two points that appear to us to have an important bearing on the matter. First, as plants in pots are affected similarly to the Vines, the foliage being hard and crumpled, you could easily ascertain whether the roots are healthy, at least up to the time that growth ceases; if they are you would have strong evidence that the cause of the injury is not in the soil. Secondly, you do not inform us whether you syringe the Vines and plants or not. The Vines are certainly in a very unsatisfactory state, and judging from your letter and a close examination of the growths sent we conclude that there has been an excess of moisture in the atmosphere of the house. The leaves appear to have been quite gorged with moisture, and it is certain they have had more than they could digest, consequently the tissue was injured and then destroyed, drying up in its present form. We are confirmed in this view of the case by the fact that the large leaves are not injured to nearly the same extent as the small; the former can to a considerable extent elaborate the moisture, the latter cannot. Are the tanks in the house uncovered? If they are very large and exposed we think they are the source of the evil, and if you syringe that will aggravate the injury. Water from chalk is not usually injurious to vegetation, and in this case we do not attribute the injury to the quality of the water, but rather to an excess of it, the growths appearing to be quite congested. If the tanks are open cover them secretly; employ the syringe cautiously if at all; ventilate freely night and day, according to the weather, and see that every leaf is exposed to the light. We should remove all the worst growths, as their retention cannot be of any benefit to the Vines, and possibly if you carry out our suggestions the subsequent growths will be more healthy. We suspect that if you were to permit a portion of one of the Vines to make growth outside the house that it would not be in the condition of the examples that you have sent to us; and if you were to prune the affected Fuchsias and plant them outdoors we think the succeeding growth would be healthy.

Insects—Fragile Boxes (*J. L. C.*).—The lid of the fragile chip box was broken in the post, and the insects appear to have escaped, for there was not one in the box on its arrival. Stout boxes or tin canisters should be employed for sending specimens. We have this week received parcels of flowers and fruit quite crushed and the contents spoiled.

Names of Fruit (*E. J. L.*).—The Strawberry is the Bickon Pine. (*R. Gilbert*).—The Strawberry is in our opinion decidedly President, but we have seen many exhibited under this name that were Sir Joseph Paxton. (*C. Bennett*).—The fruit was crushed in transit into a shapeless mass.

Names of Plants (*A. B. P.*).—7, *Carex vulgaris*; 8, *C. binervis*; 9, *Arrhenatherum avenaceum*; 10, *Bromus mollis*; 11, *Avena flavescens*; 12, *Anthoxanthum odoratum*. (*J. Woodliffe*).—1, *Philadelphus grandiflorus*; 2, *P. coronarius*; 3, *Deutzia scabra*; 4, *Campanula rotundifolia*; 5, *C. glomerata*; 6, *Centranthus ruber*. (*H. G.*).—A species of *Carex*, but the specimen was insufficient for identification. (*W. M.*).—The specimens you sent are the same as those you refer to. (*W. H. Myers*).—1, *Galega officinalis*; 2, *Tradescantia virginica*; 5, *Philadelphus coronarius*. We will endeavour to name the others in a future issue. (*F. Smith*).—*Eriophorum polystachyon*. (*J. R.*).—1, We cannot determine without flowers; 2, *Galeopsis Tetralix*; 3, *Polygonum convolvulus*; 4, *gallis arvensis*. (*Mrs. Pade*).—*Mimulus cardinalis*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE ROYAL COUNTIES (HANTS AND BERKS)
AGRICULTURAL SHOW.

THIS is the third time within eight years that this Society has visited Portsmouth, and on this occasion it was upon a greatly extended scale as compared with its first meeting. Although it rained steadily the whole of the first day, yet on the three succeeding days the weather was fine, inducing the public to visit the Exhibition in very large numbers, and in consequence the meeting has proved not only successful as an exhibition, but also financially. Having reported upon the Show on each previous occasion, we have now only to remark that it has this time far exceeded in importance any former meeting as a spectacle and opportunity for the home farmer, and business men generally, to compare and estimate the merits of the various kinds of cattle exhibited, and the use and objects of the large and varied collection of agricultural implements and labour-saving machinery. The manner in which the Show yard was laid out, and the general management of the Show, reflects the greatest credit upon the Committee and Stewards, and particularly upon the worthy Secretary, Mr. Henry Downs of Basingstoke, whose unremitting exertions and courtesy was highly commended.

We propose to make our remarks on the Exhibition as the classes occurred in the printed catalogue, taking the sheep first. Class 1, Hampshire or West County Down sheep, for the best shearling ram, four entries.—First prize (£10) to Mr. Alfred Morrison, Fonthill, Wilts; second prize, Mr. F. R. Moore, Pewsey, Wilts. The sheep, four in number, shown in this class belonged to flocks which have for a number of years taken a leading position; in fact, ever since the flocks of Mr. Jas. Rawlence and the late Mr. Humphry have ceased to be exhibited in the Hampshire Down classes. The latter are very much missed, for although the prize animals, as stated above, have been certainly amongst the best for some years past, still they are not to be compared with the stocks of Messrs. Rawlence and Humphry. It is a great loss to breeders of the present day that these breeds had not been preserved in all their purity by some eminent breeders, for Mr. Humphry once told us that it was over twenty years before he had established the fixity of type and character his sheep possessed. We find, however, that nearly all the best sheep of the present time are derived from the blood of these two celebrated flocks; and as we cannot expect in our time to see such sheep again, yet they will ever be remembered as a type, and object to be attained if possible in the future by our most eminent and enterprising breeders of Hampshire and West County Downs.

Class 3, for the best ram of any age, three entries.—First and second prize to Mr. F. R. Moore, both of which sheep were really good animals, in proof of which Mr. James Read of Honington, Salisbury, was a competitor with a good animal which was highly commended. Class 3, for the best pen of five shearling ewes, four entries.—First prize to Mr. James Read of Honington; second prize, Mr. R. F. Moore of Pewsey, Wilts. The first-prize ewes were fine lengthy animals, well made up by feeding, and they richly deserved their position. The only defect we noticed in these ewes was their long light necks, or scrag as it is called, with a rather thin shoulder top; still in this respect they are improved as compared with Mr. Read's former exhibits. The second-prize ewes were well got up and very symmetrical, the

shoulder top and neck being especially full and good, with fine quality, and short fine wool; they were, however, too short in the body in comparison with the first-prize animals, we therefore suggest that each owner has something to learn of the other before their stock will meet with our entire approval. Class 4, six entries, for shearling ewes, given by A. Morrison, Esq., of Fonthill. We, however, find little worth attention in this class, except that having been kept in the flock until within one month of exhibition they must all have been well fed during the season, especially those belonging to Mr. Newton of Wallingford, Berks, who received both first and second prizes. The other competitors had the reserved number or obtained high commendations.

Class 5, for the best Hampshire down ram lamb; three prizes given by the Right Hon. the Earl of Portsmouth; nineteen entries. The lambs in competition in this class were extremely fine, and in which many of the best and most eminent breeders of the day competed from Hants, Wilts, and Berks. The first prize was awarded to Mr. Wm. Parsons of West Stratton, Micheldever, Hants, for a lamb only about seventeen weeks old, who by gaining this prize has secured high honour, and most certainly deserves it, for we do not recollect seeing so fine a ram lamb ever before exhibited, for it must be remembered that in Mr. Humphry's time lambs were not exhibited, either singly or in pens of five, as at present. The second prize was taken by Mr. F. R. Moore; and the third prize by Mr. A. Budd of Overton, Hants, with two beautiful lambs of large size, capital quality, and great weight for age, being only about eighteen weeks old. Class 6, for the best pen of five ram lambs bred by exhibitor; nine entries.—The first prize was awarded to Mr. Wm. Parsons, the winner of the single ram prize; and this is a great victory, when we consider that the exhibitors in this class contained the names of the best breeders and greatest prizewinners in former meetings of this Society. Two of the lambs in this pen were little inferior to the single lamb in Class 5, the whole five being as fine as any lambs we have ever seen. Their quality was very remarkable as well as their size; they had plenty of firm flesh, fine wool, and were matching in colour. The second prize was taken by Mr. R. F. Moore; third prize to Mr. Jas. Read; reserved number belonging to Mr. John Barton, Basingstoke.

Class 7, for the best pen of five ewe lambs, bred by the exhibitor; eleven entries.—This was an unusually large competition. First prize Mr. Wm. Parsons, who again triumphs over all opponents, and this in a competition with experienced and most eminent flock masters at former meetings, and especially we may name Mr. Morrison, who has been at the top of the class for a number of years, and who on this occasion only succeeds in obtaining the second prize. Mr. Parsons, having in these three important classes taken the first prize in each, may be said to possess the best sheep of the Hants or West County Down breed, and this being the case his stock will be sought for at high figures at his annual ram sale, and whatever price they may make will be no more than a just reward for his intelligent selection of stock, his judicious mode of breeding and feeding, and his liberal investment of capital in stock farming. Class 8, South Down sheep, for the best shearling ram; seventeen entries.—These prizes were well contested by eminent breeders. First prize taken by Mr. H. Gorringer, Brighton; second prize to Mr. H. Penfold, Chichester. All the animals competing in this class were handsome well-bred sheep; but still we noticed that they were smaller than those formerly shown at the Royal meetings by Jonas Webb, and latterly by Lord Walsingham, and we consider this a matter of immense importance, for size should never give way to a smaller and more delicate breed of stock, seeing that in times gone by the Sussex breed from the flocks of the Duke of Richmond, Mr. Rigden, and the two breeders above mentioned, although they were of larger size, yet the highest quality of flesh and wool was maintained.

Class 9, for rams of any age.—The first prize was taken by Mr. Gorringe, the second by Mr. C. Chapman, Frocester Court, Stonehouse, and these were great honours to win, when we note that the Judges commended the whole class. This breed of sheep from time immemorial has been reared on the chalk hills of Sussex, and have contributed largely to the improvement of other breeds in Dorset, Wilts, Berks, and Hants, when the local breeds of horned sheep were given up many years ago. And in many instances in years to come they will occasionally be used for crossing and improving other stock just in the same way as Mr. Humphry improved his West County Downs by the use of Jonas Webb's rams of the Southdown breed about forty years ago, at the time of the first Royal Society of England meeting held at Oxford. Class 10, for the best pen of five shearling ewes, five entries.—This was an extremely handsome lot of ewes of wonderful quality. The first and second prizes going to the same gentleman who stood first and second in Class 9. We often hear various opinions expressed about the light weights of this breed, and as not being adapted for feeding the million, but it must be remembered that they will not only live upon scanty keep, but that greater numbers can be kept in comparison with all our larger breeds; at the same time it must not be forgotten that this stock is admirably adapted for furnishing small joints of the highest quality of mutton, and are in consequence much required for feeding the parks and pastures, and furnishing meat for the establishments of noblemen and gentlemen in various districts of England. Oxfordshire Down sheep, Class 11.—For the best shearling ram, only two entries, by the same exhibitor, Mr. G. Adams of Farringdon, Berks, who takes both first and second prizes. On referring to our notes on this Society's meeting at Southampton in 1878, we find that the same breeder took the first prize both for shearling ram and five shearling ewes on that occasion, but we did not think his stock quite so good as they were two years ago. The Oxford Downs are, however, a noble breed of sheep, being originally a cross between the Cotswold and Hampshire Down breeds. One of the first and most successful breeders was the late Mr. S. Druce of Ensham, Oxon, who commenced the cross in 1833, and later on Mr. C. Howard of Bedfordshire. These sheep are admirably adapted for crossing with the Hampshire Downs, for in ordinary farming the cross will produce 20 to 25 per cent. more lambs and give stock of a larger size and heavy weights for age, and prove better than the Cotswold cross, because they maintain a dark colour which is valued by the grazier, as they make a higher price as mutton, and yet cut a heavy valuable fleece of wool. Long-woolled sheep, Class 13, five entries. For the best shearling ram, two prizes—First prize taken by Mr. R. Swanwick, Cirencester, who also wins a Champion prize. Second prize to Messrs. Gillett, Farringdon, Oxon. These were magnificent sheep as regards size and weight for age, and would certainly stand well in any exhibition in the kingdom. Class 14, five entries. For the best ram of any age.—Messrs. Swanwick & Gillett stand in the same position as in Class 13 with grand sheep, well meriting the prizes obtained. Class 15, for the best pen of five shearling ewes.—Messrs. Gillett obtained both prizes in this class, which are remarkably fine specimens of the Cotswold breed, and will go far to ensure success to the owners at future exhibitions. The Judges in all the sheep classes were Mr. John Ford of Rushton, Blandford, Dorset, and Mr. J. R. Neate, Micheldever, Hants, both of them gentlemen of great experience, and we find that their awards have given great satisfaction to the exhibitors in all the classes.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The horses will have constant work and of various kinds. Ploughing, working with harrows, &c., after green crops will now be going on in preparation for drilling with turnip seed. This is now a good time for sowing turnip seed for a crop for winter use, as they are sure to stand the frost if not sown too early; at least this applies to the Grey Stone and Red Mammoth varieties, the two varieties which we recommend for general use and purposes, being not only quick of growth but very nutritious, and maintain their feeding quality for a long time. The sooner the seeds of turnips are drilled after the land is ploughed the better; we often drill the seed the same day the land is ploughed, especially when the land is likely to become too dry. Hay-carting and stacking will still be going on; our usual plan is when the weather is favourable to work the horses on the land up to midday, and cart the hay to rick in the afternoon, because we have always found hay in better condition after midday than in the morning if the weather is settled fine. The growth of hay for sale is attracting more attention than usual at present, and the land should be seeded accordingly. For instance, the planting of broad clover alone cannot with certainty be assured on any land; we therefore advise that 8 lbs. of broad, 4 lbs. of alsike, and 1 bushel of giant saintfain seeds per acre should be sown upon ordinary mixed soils or strong loams, but without any rye grass of

any sort in the mixture, and particularly when the land is intended to be sown with wheat afterwards out of clover lea. Now this mixture will produce hay of the very finest quality, an important matter when grown for sale, and with saintfain in the mixture it can be made into hay in nearly as little time as with rye grass, and the hay will be worth from 10s. to 15s. per ton more. Let us consider the probable produce per acre, and as this mixture of grasses will produce two good cuttings, we may therefore calculate that 3 tons per acre at least will be the result; the value of £4 per ton may be expected upon the average, although sometimes a portion may be partially damaged, making £12 per acre. This compares favourably with any cereal production at prices which we are likely to obtain whilst unlimited importations prevail. If, however, the sale of hay is not intended we advise the home farmer not to risk the making of hay, but to cut the clover, &c., as a mixed crop for use as required. Three cuttings may then be often obtained upon good holding land and be employed as green fodder for the cattle in boxes, the dairy cows in stalls, and horses in their stables, the dairy cows receiving a bait night and morning at milking time, thereby supplementing the food whilst grazing on the pasture or park lands. In this way the clover crop takes but little labour and no risk, and resulting also in the making of large quantities of valuable manure. There is another plan of furnishing dry fodder which we wish to lay before the home farmer, the growth of which, too, will furnish a good alternation with clover (which on many soils is an actual necessity), we mean the conversion of green rye or winter oats into hay. Where the land is free from couch grass these crops may be sown and removed in time for the growth of crops of mangolds, Swedes, early turnips, cabbages, and carrots planted or sown in good time. In ordinary seasons the rye or oats being cut and tied into small sheaves, and half the land being ploughed between the stooks of straw set up, these may then be moved on to the land just sown and the remainder of the land drilled, and as soon as the sheaves are dry enough to be stacked for hay they may be removed. Upon this system there is little if any risk of damaging the "Prairie hay," as we call it; for it will come out of the stack a wet brown colour with much aroma, and of great feeding value, as shown by the analysis of straw cut green by Dr. Voelcker, and far better for feeding fattening cattle than any hay, and also well adapted for chaffing for horses, sheep, dairy cows, &c.

Hand Labour.—This will now be required in many different kinds of work; and in order that hand labour may be available for the work of the farm, labour-saving machinery of every kind should be employed as much as possible, but especially the straw elevator at the time of stacking the hay. The second and last hoeing of mangold should now be done, the hoeing of Swedes, also of all root crops as they become fit, and when the plants are large enough for singling the work should never be delayed. Shepherds now will find abundant employment, for this is the time for weaning of the lambs, and it is well to remove the ewes from the lambs instead of the reverse course. The lambs will be more contented after losing their dams if allowed to remain a few days in the field or pasture where they have been accustomed to be fed, and especially if they have been allowed artificial feeding stuffs, such as cake of any sort, cracked beans, &c., Dairy cows in hot weather often receive but little attention, and are allowed to take the shade of trees; but we prefer if near the home-stead to take them to the stalls out of the way of the flies, and give them a bit of any green fodder, remaining until milking time, they will then give down their milk more freely, and more of it, than when under trees or hedges, where their manure is also lost. The home farmer should now be prepared with a well-bred yearling bull in readiness to be turned out with the yearling off heifers the first week in August; the calves will then be due in May, when the grass will be ready for the heifers after calving, as they cannot be kept too well, a flush of milk being desirable, and in the first year the calves should be allowed to suck until fat, and also others afterwards for veal. This improves the animals ever after as dairy cows.

ROYAL AGRICULTURAL COLLEGE.

THE Principal of the Royal Agricultural College, Cirencester, feeling that it is in the highest degree desirable that members and past students of the College, and other gentlemen having special attainments in science or having experience as agriculturists and stock-keepers, should co-operate with the professors and students of the College in agricultural research, invites qualified persons to assist personally or by letter in the following investigations. For the attainment of the objects in view it is proposed to establish the following Committees, each having its own special line of research—

1st, *Live-stock Committee.*—To inquire into the means for regulating the breeding powers of animals. (a) Conditions favourable for reproduction; (b) conditions which prevent reproduction; (c) conditions controlling the sex of offspring; (d) conditions influencing the colour of offspring; (e) any other branch of the inquiry which may be considered desirable.

2nd, *Meat Committee.*—(a) Conditions favouring the economic production of meat; (b) conditions which influence the quality of the meat produced; (c) any other branch of the inquiry which may be considered desirable.

3rd, *Farm Seeds Committee.*—(a) Conditions which influence

the suitability and the productive powers of farm seeds on different soils and in different districts; (b) conditions regulating the change of seed; (c) any other branch of the inquiry which may be considered desirable.

4th, *Plant-growth Committee*.—Evidences given by plant-growth as to the quality, composition, and capabilities of different soils and in different districts.

The work proposed to be carried out by the above-named Committees will not in any way interfere with the prosecution of research into other details of agricultural science in which the staff of the Royal Agricultural College is or may be engaged, as it is intended for an additional series of investigations.

"THE PERFECT MILK PAIL."

WE were much annoyed, not to say disgusted, this spring by a dust—so fine that it passed through the strainer—falling from the cows into the milk pail, and the utmost care of the dairymaid could not prevent it. The animals were not in any exceptionally dirty state, nor were they at all unhealthy, but from being housed through the long winter and spring their coats were charged with this fine dust, which fell into the open-mouthed pail at every movement. That this is no uncommon evil would appear from an American invention apparently intended expressly to counteract it. This is called "the perfect milk pail," and it certainly would exactly have met our difficulty had not the advancing season, bringing a turn-out of the cows, come to our relief. But

Fig. 11.

winter troubles will be coming round again, and possibly some enterprising reader of the *Agricultural Gazette* may already be able to pronounce on the pail, or be disposed to go in for a trial of it.

The manufacturers claim for it "that the milk is so enclosed that it cannot be reached by any effluvia, to say nothing of its freedom from filth." It is a strong fourteen-quart pail with a dishing cover forming the milker's seat. A milk receiver or funnel projecting forwards and upwards from the top of the pail has a wire gauze strainer inside; and the stiff rubber tube, by which it is attached to the pail, being flexible, it can be readily turned aside if the cow starts or kicks, or while brushing the bag, or making other convenient arrangements conducing to cleanliness, freedom from odours, &c., all of which are most desirable conditions of dairy management; and, to be effectual, should commence at the time of milking, as no later care can undo evils contracted then. —A. L. O. S. (in *Agricultural Gazette*).

[We are enabled to give an illustration of "The Perfect Milk Pail," through the kindness of Messrs. Carson, Bachelor's Walk, Dublin, who furnished us with the block.—EDS.]

THE FOWLS OF THE MEDITERRANEAN.

THE nomenclature of our breeds of poultry and Pigeons has not always been fortunate, and when once a race has become popularly known by some incorrect name it is next to impossible to get it changed. Cochins will always so be called in spite of the now

undisputed fact that their home is China, where they have for ages been known in what fanciers would call an "unimproved" form. Hamburgs and Polish will still keep their names, in spite of the fact that no possible connection can be found between them and their reputed countries. With some races it is otherwise. Spanish, and the various sub-varieties of the breed which we know as Minorcas, Andalusians, &c., belong certainly to a breed which has been long spread over the Peninsula. As we find the French breeds here and there where attention has been given to poultry kept in purity and with regard to certain points, but for the most part greatly confused, so the Spanish breeds, retaining some general and defined characteristics of form in all minor points, are found of the most charming variety.

The object of this present letter is not so much to speak of the fowls of the Mediterranean in general as of the Leghorn or Italian breeds in particular. If my memory does not deceive me, the Brown and White varieties of Leghorns which have become so soon popular in England, came to us first from America, bringing their name with them. For once in a way there seems to have been really some reason for their bearing it. Doubtless birds of a certain degree of purity had gone straight from the port of Leghorn to some fancier in America, who appreciated the merits of the race and attempted to improve it. When Leghorns were far less known than now I was one struck by the size and excellence of the eggs at an obscure village in the Alps at the extreme edge of the Italian frontier. I asked to see the fowls that laid them, and was not a little surprised to find them very fair specimens of the two breeds of Leghorns, all of course mixed together, and one or two hens among them of the same characteristics, but varying in colour. Since then at various times I have been able to observe the poultry in almost every part of Italy, and have found them more or less kindred to this breed from the French frontier to the Adriatic, and from the Alps to Cape Spartimento. At Leghorn, however, and in the neighbouring part of Tuscany they are decidedly finer than elsewhere and far more uniform in characteristics. I have specially observed some pretty Cuckoo specimens, and fancy that the admirers of the breed would not find it difficult to procure birds from which to raise a permanent Cuckoo variety. For the most part through all the Italian peninsula the peculiar single comb, the Leghorn carriage, and yellow legs are everywhere seen in the poultry. As to size the fowls are simply miserable. Everywhere they show signs of degeneracy and starvation. I do not remember where or by whom Spanish and Spanish sub-varieties were first classed with Leghorns as "the fowls of the Mediterranean;" certainly the classification was a very apt one, for there is a most distinct relationship between these Spanish and Italian races in spite of their differences, especially of colour. In both the single comb is almost invariable, in both the general form and carriage is alike; both are good layers of—for their size—large eggs, and both are poor mothers. Here in

Sicily I still find some birds of the Leghorn type, but there have also evidently been many importations from the East and Spain. Feather-legged and Spanish-like birds both abound in the ports, and the result is that the common street fowls are at least twice the size of those in Italy. These constant importations seem to have invigorated the gallinaceous race as much as the various waves of immigration have the human population.

Those of your readers who have shown so much spirit and perseverance in the improvement of Leghorns may be glad to know that their favourites evidently have a pedigree in the land of their origin.—O. ERNEST CRESSWELL, *Syracuse*.

BIRD BREEDING—MULES AND HYBRIDS.

IN reply to questions from Mr. H. M. Buffham relative to breeding with the Canary and Yellowhammer or Chaffinch, I have never heard of the Yellowhammer (M'Gillivray) or Yellow Bunting (Bechstein) breeding with the Canary, and after the two blank nests of eggs I think it would be hopeless in further pursuing the matter. The Chaffinch (Fringilla) might be the more likely of the two to cross with the Canary, and even from this particular Finch the obtaining of mules would be still more rare than young from the Bullfinch and Canary. Bechstein says—"Instances have occurred of Chaffinches pairing with female Canaries and producing hybrids, and it is also said with the Yellow Bunting." During many years' experience and knowledge of the various crosses in breeding mules or hybrids I cannot bring to mind an instance of a mule having been bred from the Chaffinch and Canary. Yellowhammers and Chaffinches make

very good aviary birds in company with the Goldfinch, Bullfinch, Mountain Finch, Linnet, Greenfinch, Siskin, and Redpole. The offspring of the Siskin and the Canary is very prettily feathered and sometimes nicely variegated, and they make sweet songsters brought up within the hearing of a good Canary tutor.—G. J. BARNESBY.

VARIETIES.

GREAT AUK EGGS.—Two genuine eggs not previously recorded were lately discovered in an old private collection in Edinburgh, and some of the leading naturalists being of opinion they may be the last unrecorded specimens that will be found, were sold on the 2nd inst. by Mr. J. C. Stevens, 38, King Street, Covent Garden, London. One specimen for £100, and the other for 102 guineas.

BUTTERCUPS IN PASTURES.—A correspondent, "NORTH WOOLTON," writes in reference to our advice given on page 20—"There is no need to burn the turf. Geese will take out all the bulb roots of the buttercup; when there is a great many to root out time must be allowed." To this we reply there are two species of *Ranunculus* in pastures which are known by the name of buttercups—*R. bulbosus* and *R. repens*. It is the former that geese devour with avidity; the latter must be eradicated by weeding. The tall *R. acris* is also a buttercup, and is abundant in some pastures.

PEDIGREE CORN.—An experienced correspondent writes to us as follows:—"Farmers, although growing full pedigree corn, have made serious mistakes in consequence of expecting to obtain large ears of corn—either of wheat, barley, or oats—when the land has not been rich enough to produce a full crop; but it will be found that pedigree corn will require the land to be properly tilled and manured, and will then yield a more valuable produce than ordinary grain. It is also necessary to have the land deeply tilled for pedigree grain, but especially for wheat, because it will root very deeply, say several feet, if the roots can penetrate the soil; and we draw a comparison in the rooting of grain to that of timber trees, the wheat rooting deep like the oak, whereas oats and barley, but particularly the latter, root near the surface, more like the ash and the elm. The change of seed from different soils has always been recognised as advantageous, especially when taken from the poorer soil to the better. There will be, however, some difficulty in the change of seed of pedigree grain unless pains are taken to obtain for a surety seed selected by the grower, or otherwise the home farmer may by his own intelligence and care provide seed of his own growth, particularly where the necessary variations of soil occur upon the estate or occupation in hand. In conclusion, we feel that whatever views farmers in general may entertain as to the merits of Major Hallett's system of growing pedigree corn, the principles upon which he has acted are correct—that in Nature like produces like; and that he has bestowed greater attention upon the subject than any other man, and that his exertions are worthy of our high commendation."

"THE MARK LANE EXPRESS."—This important agricultural paper has appeared this week in a new form, and not only new, but decidedly much improved. The pages are much smaller than before and proportionally more numerous, and the paper is more handy for reading and convenient for binding. We say nothing about the improvement relative to the quality and variety of the matter, for in these respects it was good enough before: but the most welcome change of all is the change of price, which is reduced to 3d.

OLEOMARGARINE.—Last Saturday's issue of the *Irish Farmers' Gazette* gives full details, with illustrations, of the manufacture of this article in America from beef fat, and remarks that as it is the producers of second-class and inferior qualities of natural butter who suffer most from the competition caused by the introduction of oleomargarine, it is evident that the only way in which that competition can be met is by improving the quality of pure butter. In this, as in the case of cattle, the home-made and home-produced article will maintain its ground against foreign competition, provided it is of superior quality. Producers of inferior articles, whether meat, butter, or cheese, have now no chance in the market. At the same time we are of opinion that there should be some legislative action taken with regard to the sale of oleomargarine, so as to protect consumers who may purchase it under an impression that it is genuine natural butter.

THE HARVEST IN ITALY.—The Italian Minister for Agriculture and Commerce, in his monthly report for June, says, "The state of the country is very good, and promises a rich harvest in all products. Grain could not be better; the harvest has already begun in the southern provinces, and is equal to expectation. Maize is also in fine condition. The vines, except in some places where they were damaged by the frost, promise a copious harvest, and so do the olives. The harvest of cocoons is most abundant, except in a few places such as Belluno, Como, and Modena, but prices are unsatisfactory. Other products, such as oranges and lemons, fodder, &c., are in excellent condition, with the exception of hemp, beans, and a little fruit in some localities."

PEKIN DUCKS IN AMERICA.—A correspondent of the *Prairie Farmer* writes as follows in reference to this breed:—"I speak from several years' experience, and I say that so far as my knowledge extends the Pekins are decidedly the best breed of Ducks that we have in this country—best for laying, best for feathers, best for the table, and best for market, and I shall raise them as long as I keep Ducks, or until I find a breed that suits me better. I don't raise Ducks for the fun of the thing, or to look at, or to brag about, but for profit, and I can get more profit from the Pekins than from any other breed that I know anything about; and just so soon as I find a more profitable breed of Ducks I shall acknowledge the fact, invest in the Ducks, and advise others to go and do likewise. I don't want to keep all the good things to myself. I raise poultry for market almost exclusively, and have sold dozens of pairs of these Ducks that weighed from 20 to 22 lbs. per pair fattened for market; 22 lbs. is considerably above the average weight of the best breeding stock; 15 lbs. per pair probably comes nearer the average. The first pair of Pekins that I ever owned weighed 16 lbs. when the Duck commenced laying in February, and I now have a pair that weighed 18 lbs. the 1st of March. There is no secret about this gain above the average weight; anyone can attain the same results by proper selection of breeding stock, and by care and abundant feed. I never allow an inferior or undersized Duck in my breeding yards; I always breed from the largest, most vigorous, and fully developed birds that are at least two years old; and from the time the ducklings are out of the shell until they are sent to market I give particular personal attention to their care and food."

EARLY PROGRESS OF CHEESE FACTORIES IN ENGLAND.—The quantity of cheese sold at the Derby factory in its third season was over 49 tons, and the average price realised 74s. 7d. per cwt.; the total cost of manufacture 7s. 1½d. per cwt. of the cheese; and the dividend paid on the milk within a fraction of 6¾d. per gallon. Notwithstanding various drawbacks, the year 1872, the third season of the two factories, was one which added credit to the factory system; for, after paying all expenses, a higher price per gallon of milk was paid than when the guarantee fund was in force, and this in spite of the price of cheese having declined several shillings per cwt. This result was highly creditable to the skill, the industry, and the perseverance of the respective committees, as it was an encouragement for the future. In the fourth season the milk-suppliers purchased the plant from the guarantors, taking full possession as well as entire management, and doing away wholly with the connection which till then had been maintained with the guarantee fund. Meanwhile the price of cheese had been advancing, and the results of the fourth season at Longford were more favourable than any of the preceding ones; the management and the manufacturers were alike thoroughly successful, and the business was a pronounced success.—(From "*Dairy Farming*" by Professor Sheldon, for June.)

DEATH OF MR. JOHN HUNTER.

WE last week announced the death of Mr. John Hunter, the distinguished apiarian, and we now give the following notice of him extracted from the *British Bee Journal*:—

"Mr. Hunter was born in London December 10, 1831. He was the second son of Mr. James Hunter of Bloomsbury, who was the founder, and for thirty-eight years the secretary, of the Royal Standard, one of the largest and most successful benefit societies in the kingdom. Mr. John Hunter was one of the originators of the British Bee-keepers' Association, and his interest in its welfare

he retained to the last. He was the author of the 'Manual of Bee-keeping,' which has now attained its third edition. He was the writer of the article 'Bee' in the last edition of the 'Encyclopædia Britannica'; also, in 1875, of a pamphlet entitled 'The Cottage Frame Hive,' specially written for the use of cottagers. He was for several years on the staff of the *Journal of Horticulture*, and also on that of the *Gardeners' Chronicle*, and was a constant correspondent to both British and American apicultural magazines. Many contributions from his pen will be found in the earlier volumes of the *Journal*. The paper which he read at the *Conversazione* on April 14, on 'The Future of British Bee-keeping,' will be fresh in the recollection of our readers. Mr. Hunter was selected by the Committee of the British Bee-keepers' Association, together with Mr. Cheshire, to compile the 'Handbook for Cottagers.'

"At the South Kensington Show in 1878 Mr. Hunter was awarded a silver medal for a very fine collection of microscopical objects illustrating the natural history of the honey bee.

"He was a member of the Quekett Microscopical Club of London, and also of that in Ealing; and on October 25, 1878, he read a most interesting paper on 'The Queen Bee, with especial reference to the Fertilisation of her Eggs.' This paper was published in the *Journal of the Quekett Club*. He was also for many years a member of the Entomological Society.

"Mr. Hunter's exertions and spirits were always in excess of his strength. He had been in very delicate health for many years, and succumbed after an attack of pleurisy, culminating in congestion of the lungs, of less than a fortnight's duration, at his residence at Ealing, on Sunday, the 27th June. His death will be a very great loss to the cause of bee culture and science in general."

EXPERIMENTS WITH FOUNDATION.

THE proverb "Time tries all" contains more than a little wisdom, and in order that all I have done with comb foundation might have that testing that time alone can give, I have remained silent for a week or two, but now proceed to conclude and summarise an account of the results obtained.

Mr. Jones, well known amongst apiarists as our Canadian cousin, who has with great pluck and energy secured, during travels undertaken for the express purpose, a large number of Cyprian and Holy Land bees, visited me a few days since in company with Mr. Hooker of Sevenoaks. Mr. Jones expressed very strongly his delight at the perfection of the combs produced, and at the simplicity of the means used, making wired foundation, even if it worked perfectly, unnecessary and uncalled for; but he quarrelled with the name "rakes," and there and then we agreed to the suggestion of my visitors that these wires should henceforward be called Cheshire's Foundation Fixers.

The fixers, up to the date of my last notes (page 425 of your last volume), had always so held the foundation that perfect combs made in stocks had been produced, and the experiments with swarms remained to be tried. I filled eight frames with foundation from top to bottom and end to end, did not wax-in any of the sheets, and gave to some five and to other six fixers. The swarm, a large one, hung principally on four combs. No sagging whatever occurred, but one comb bent slightly over for about $1\frac{1}{2}$ inch at the end, so that its edge for this length was not fixed quite in the middle of the top bar. Another swarm has been tried, receiving six sheets of foundation held by the fixers, and two of wired foundation. The first six sheets are now perfect combs; one sheet of wired foundation is waved or buckled a good deal at its lower part, the other is perfect. My conclusions are these:—With stocks the fixers are alone quite sufficient; with swarms it is wiser to wax to the top bar as well as use the fixers. That foundation should in no case extend quite to the bottom bar. I brought my sheets into contact with it, in order that the smallest stretching might make itself apparent, but the bees object; they are slow in finishing the lowest cells, and often nibble for themselves passages through the foundation above the bottom bar. It is clear also that the absolute filling of the frame with comb would oblige the queen, to her great risk during an examination, to continually pass from comb to comb on the outside of the frame. Although, then, the fixers admit of filling the frame, it is unwise to take advantage of it. A bare quarter inch beneath and at the ends should be left. The fixers must also be put into place by the assistance of the wood block as explained in the issue of May 27th, for if the pin be clearly and at once pierced into the sheet it holds with wonderful firmness, but if it be twisted about afterwards it enlarges the hole and loses its grip. When the sheet is given the first effort of the bees is to fix the pins, building around them little struts of wax; but if a tiny hole be made near to the pin the bees on the opposite side of the sheet seem to communi-

cate through it and dig away the wax around the pin until a hole nearly half an inch in diameter is made, it would appear with the idea of removing what they regard as an obstruction. All this will show the importance of fixing at once the foundation in its proper place. The pertinacity with which the bees build drone comb, cut out often by the vexed bee-keeper to be immediately replaced by more, many know to their chagrin; while the loss this involves, many, though a less number, understand. Here, however, we have the perfect cure for the evil, and a power of rapidly building up stocks with faultless comb which the old jog-trot bee-keepers find it hard to believe and impossible to realise. I am fully convinced that the proper, intelligent use of foundation in full size will double the produce and quadruple the pleasure to be got out of any apiary.

But it may be that these fixers will be useful, not only in preventing sagging and in securing perfect flatness in the comb, but in making it possible for new comb to travel. Last year at South Kensington was exhibited a sheet of foundation from Alsace, with a thin board between its faces. This foundation on wood has been tried in America and pronounced a partial if not a total failure. Mr. A. J. Root of Ohio thus speaks of it in his useful "A B C of Bee Culture"—"In our apiary I have beautiful combs built on thin wood; but as the bottom of the cells is flat they are compelled to use wax to fill out the interstices, and the value of this surplus wax, it seems to me, throws the wood base entirely out of the question." Mr. Abbott, however, has been following out the idea of trying flat-bottomed cells on thin pine boards, and has succeeded in getting some of these built out perfectly, so that he is sanguine of success, which I see nothing to prevent, since bees can be made with a little management to build brood or store cells even on the top of sealed honey cells. I have more than one specimen now of comb, thus having three cells in cross section, two of honey, and one of brood. Should he succeed these combs would admit of any roughness during transit; but pending this result it will be interesting to state that, having to take a stock of bees in a frame hive to Peterborough, I put into the stock on a Monday morning a full-sized sheet of foundation, using my fixers. On Tuesday morning the hive had three distinct journeys by cab and two by rail, while the bees were shut up for twelve hours. The foundation converted into comb arrived in perfect order, and has made the return journey without injury. The continuance of the wires in their position will cause the loss of less than twenty cells in all.

I have been requested to state some particulars about size of wire, &c., and so add that the wire I used is best quality, No. 18 tinned wire, upon which pins are soldered by their heads at intervals of $1\frac{1}{4}$ inch. That the pins are afterwards cut down to half an inch in length, and the wire turned to a right angle top and bottom so as to just slip over top and bottom bar. These fixers with the boards can be had, I believe, of Messrs. Neighbour.

Let me here say that foundation for hives should be thick, and that thin sheet, such as is suitable for supers, would fail if treated as described.

Not only have I had the pleasure of showing these matters to Mr. Hooker, but to Mr. Cowan also, who had good opportunity of seeing the destruction of brood produced by wired foundation. I mention this that in the mouths of two or three witnesses every word may be established. The latter gentleman gives us a new suggestion by saying in a letter to myself, "I have given your 'foundation fixers' a good trial and find them most effectual. I had a lot of pieces of foundation in strips about 3 inches wide. I cut their sides parallel, squaring the ends, and fastened them into a frame with your fixers. They are all joined together and worked out, so now I shall not throw away any scraps."—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

PIPING QUEENS.

I AM much obliged by Mr. Pettigrew's reply to my letter in the *Journal* of the 17th inst., and am now in a position to give further information regarding the two young queens. The one Mr. Pettigrew would term the "barking queen" has been duly fertilised, and three of the frames now contain a large quantity of sealed brood, &c.; but unfortunately the "piping queen," and consequently the older and the one to which most interest would attach, has been lost. I made no mistake as to the queen that left the hive, as she alighted on the ground in front of the hive, and I had a good opportunity of observing her. Mr. Pettigrew in his book states, "The eggs of virgin or unmated queens are male in character," but I take it this does not imply that a virgin queen can become a breeder of drones. Will Mr. Pettigrew inform me if I am correct?—M. H. MATTHEWS.

[In answer to the question at the close of the letter above, I have to say that virgin or unmated queens are all drone-breeders.

I am obliged by Mr. Matthews' letter, though it still leaves me in uncertainty as to the age of the young queen at the time of fertilisation.—A. P.]

FACTS ABOUT SWARMING.

SWARMING is natural to bees, and they prepare for the important event a long time before it takes place. Royal and drone cells are built, and when the time draws near such cells are filled with brood. Some small hives have been filled with combs without any drone cells; but in such cases, which are very rare indeed, the bees hatch a few drones in worker cells before or at the time of swarming.

Bees swarm in the first case by want of room. The populations of hives healthy and prosperous rapidly increase from March till May or June, when they begin to send off colonies. The clustering and accumulation of bees at the doors and outside the hives before swarming is of common occurrence in apiaries of small hives. In apiaries of large hives clustering is very unusual—hardly ever seen. Hence the first swarms of small hives are larger in proportion to size of hives than those of large hives. Perhaps the difficulty of ventilating hives of great capacity may be the cause of this difference. It is well understood that large hives yield larger swarms than small ones, though the first swarms of small hives are proportionately larger. This is not the case with second swarms or casts, for those from small hives are comparatively worthless, whereas the second swarms of large hives often rise in weight to 60 and 80 lbs.

It is noticeable that first swarms generally alight near home, and thus their queens can go with them without much fatigue. Second swarms with young virgin queens often settle at greater distances from their hives. Second swarms are less particular as to fine sunshiny weather at the time. Why swarms settle at all on trees and bushes near their hives is a question not easily answered. They do so from instinct, and in my opinion without ulterior intentions. Some writers think that they have ulterior intentions, and in alighting on a tree they are simply congregating and resting before they start for a new and distant home. I cannot take this view, for very often unhived swarms will hang for a couple of days, and when they go they again alight on a tree, and go from place to place without finding a suitable abode to live and labour in. Sometimes they find an empty hive, cavity in a tree or house, before swarming, and go direct to it.

When swarms alight it is desirable to have them at once and place them where they have to stand, then if the weather is unfavourable for outdoor work, to give the bees something to do indoors. I repeat what was stated lately in this Journal—viz., that no money spent in the apiary will secure a greater return than what is spent in feeding swarms after being hived. Swarms on being hived are placed at a disadvantage and have great difficulties to meet at first. Wax has to be secreted for comb-building, and foundations for the combs have to be laid. When this work begins more materials are produced than can be used, and hence the boards of hives become covered with scales of wax during the three first days of comb-building by swarms. As the combs enlarge and broader foundations are laid more workers can help. The feeding of swarms promotes comb-building and brood-rearing to a great extent. After the combs are of some size the bees seldom lose or drop the scales of wax. First swarms have pregnant queens, and hence it is of great importance to encourage comb-building at first in their hives to prevent the loss of eggs. The queens of second swarms do not begin to lay for eight or ten days after swarming. But even in their case it is advisable to feed during inclement weather. Hunger swarms are those that are starved out. Having no food and no brood to attend to they abandon their hives in despair, and often die of cold and exhaustion.

Some seasons bees swarm more readily than they do in others. The cause of this is unknown. The present season is remarkable for swarming. Bees set queens and swarm before they are fully mature, sometimes before their hives are filled with combs. In four cases this season I have been saved the trouble of swarming artificially by finding the swarms hanging on trees near their hives. Second swarms, too, are yielded as readily as first swarms.

In hot honey seasons swarms are smaller than they are in worse seasons. This is easily understood, for as bees do not sit on honey their space is contracted by all the honey they gather and store up, and this too contracts the brood combs; hence hives filled with bees and brood instead of honey yield the largest swarms.

The practice of giving swarms second-hand combs (hiving them amongst combs formerly built and used) I have abandoned. If the second-hand combs are young and clean they appear to be and are of advantage to the swarms at first, and may in certain seasons be of advantage all the year through, but generally speaking

swarms that are housed in empty hives and receive a fair start at comb-building succeed better than those which receive combs.

After these commonplaces let me repeat what I have previously said, that age and experience increase my confidence in the swarming system of management.—A. PETTIGREW.

OUR LETTER BOX.

Young Ducks (Alderhurst).—There is little difference between barleymeal and oatmeal, so we employ the first named because it is cheaper. It is not necessary to boil it. It may be made into a paste with warm or cold water.

Feeding Cygnets (K. Y.).—The proper way to feed cygnets is to give them bran, oats, and meal in a large flat vessel, the bottom of which should be covered with gravel or a sod of growing grass, the food placed on it, and the whole covered with water. Cygnets, and even grown-up Swans, love to make "little dirt pies."

Canaries Troubled with Vermin (Embrey, Derby).—Your Canary is troubled with the red mites, which is the cause of so much uneasiness at night time. Pursue the plan we recommended in No. 1003, page 486, and you will rid your Canary of its tormentors. A white linen cloth thrown over the cage at night time is a better test to prove that there are vermin than placing the cage over a sheet of white paper. But why do either and prolong the annoyance to the bird? At once lay siege to the cage and uproot the enemy.

Bees Killing Drones (Juvenis).—Your treatment of your bees is quite correct apparently. The bees killing their drone grubs is a good sign. They have given up further swarming.

Bees—Dead Grubs (N. McA.).—The grubs having been simply wrapped in paper and enclosed in a letter met the fate that might have been expected. They were completely crushed, and it was impossible to examine them. If you will send others in a small box as soon as possible they shall have our attention.

REMARKS.

27th.—Very bright fine morning, in middle of day some heavy clouds about, fine bright evening.

28th.—Breezy, but very fine warm day.

29th.—Fine and bright, rather overcast at intervals.

30th.—Fine bright day, rather overcast in afternoon, beautiful evening.

July 1st.—Morning damp and rainy, thunderstorms and very heavy rain from noon to 2 P.M. In the five minutes between 1.56 and 2.1 P.M. 0.21 inch of rain fell.

2nd.—Quite like a warm April day, sharp showers with intervals of sunshine, overcast evening.

3rd.—Rain in morning and very heavy thunderstorm 6.16 to 6.40 P.M., with excessively heavy rain.

Temperature near the average, rainfall owing to the thunderstorms considerably above it.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 7.

THERE are unmistakable signs of the London season being over, prices falling considerably during the week, especially among best goods. Vegetables are in plentiful supply.

A WEEK OUT.—No. 1.

REMPLOYERS lose nothing by giving their gardener a week out; and if, as in my case, they desire him to extend the time, and are also willing to defray the cost, the result is of mutual advantage, for while I am benefited by the change, I am bound by every means in my power to render my services in the greatest degree satisfactory to those who have such claims on my efforts. My primary object in visiting the metropolis was to see a [London show—the Summer Show of the Royal Horticultural Society. I found it a good one, and as it was fully described in the Journal I will only say that the *Cattleya gigas*, a single, not a “made-up” specimen, exhibited by Sir Trevor Lawrence with a dozen spikes, some of them with six flowers, was worth a journey of nearly three hundred miles to see.

As the notes I took during my “week out” may possibly be of interest to your readers, I commence by narrating what I saw at

KEW GARDENS.

Upon application at the Curator's office I was affably granted admittance early in the forenoon of June 9th. The registration of name, residence, and object of visit gave free access to the finest collection of plants in the world. The privilege of a morning visit cannot be too highly valued by those from a distance, especially gardeners. In the grounds *Abies Smithiana* struck me as particularly fine, having a graceful drooping habit; it is one of the most handsome of the Firs. *Cupressus nutkensis* (*Thuja borealis*), here, as everywhere that I have seen it, one of the finest and hardiest of Conifers, of stately pyramidal habit. *Æsculus carnea* (*rubicunda*) was in grand flower, and deserves to be more extensively planted. *Cladrastris tinctoria*, with bright green foliage and fine round head, would be useful in ornamental planting. The Guelder Rose (*Viburnum Opulus*), with its balls of white flowers was very effective. *Yucca recurva* was apparently much injured by frost, also *Laurus nobilis* (Sweet Bay), but starting freely. *Sequoia sempervirens*, injured by frost, but the contrast between the present and last year's growth was very noticeable. *Abies Douglasi* was also remarkable for the contrast between the old and new growth. *Jasminum revolutum* was fine as a wall plant, profusely flowered, yellow, and very fragrant. *Prunus triloba*, very free-flowering and vigorous, in a similar position. *Euonymus radicans* makes a fine wall plant, and there may be seen what can be done with Ivies as pillar plants, *Hedera canariensis aurea maculata* being very fine.

AQUATICS.—*Villarsia nymphaeoides* with fine floating leaves, to be succeeded by flowers by-and-by, was very distinct. *Caladium canadense* with arrow-head-shaped leaves, and petioles spotted with black, very fine; and not less so was *C. virginicum*, with pale yellow leaves in both instances rising above the water. *Typha stenophylla* and *T. angustifolia*, fine Bamboo-like plants, had a telling effect. *Lysimachia thyrsiflora* had yellow spikes of bloom, very fine, and much frequented by humble bees. *Littorella lacustris*, very pretty, grass-like, fine for margin of shallow water. *Juncus communis effusus*, with corkscrew-like leaves; very distinct. *Potentilla Comarum*, purple Burnet-like heads of flowers; effective. *Equisetum limosum*, of stately habit, leaves finely ringed; grand. *Acorus japonicus variegatus*, of stately growth, leaves banded with white; having a beautiful effect. *Iris sibirica alba*, white flowers; very fine. The Cotton Grass (*Eriophorum polystachyon*), fine. *Aponogeton distachyon* was in flower. There were, of course, Nuphars and Nymphaeas, but only having a display of leaves. Among bog plants grown in pots or pans the following were noticeable:—*Primula luteola* with long serrated leaves, Cowslip-like flowers, yellow, very pretty; *Epilobium longipes*, very beautiful; *Darlingtonia californica* appearing quite happy, as also the lovely Sundew (*Drosera rotundifolia*); *Sarracenia purpurea*, fine in flower; *S. flava*, quite yellow flowers; *Ranunculus Flammula*, yellow starry flowers, pretty; *Mentha aquatica* with purplish leaves, very distinct; and *Lysimachia rivularis*, of creeping habit.

HERBACEOUS GROUND.—*Polygonum molle*, with fine heads of bloom, forming a plant a yard high, flowers white; fine for any purpose. *Polygonum sachalinense*, grand foliage plant; leaves broad and distinct, growing 8 to 9 feet in height; fine for lawn. *Glyceria maritima*, fine tufty Grass, effective from its flowers. *Hablitia tamnoides*, a fine pillar plant of Hop-like appearance. *Aristolochia Clematitis* had pale green foliage with yellow flowers; the Spiderwort (*Tradescantia virginica*) having effective blue flowers. *Polygonum alpinum*, white, showing how fine it is for decorative purposes. Rain commencing to fall sharply I had only time to notice among the hardy Orchids *Orchis maculata*, *Habenaria bifolia*, white and sweet-scented flowers, and the fine purple-flowered *Nigritella angustifolia*.

CAPE HOUSE.—*Gladiolus Colvillei alba* in fine flower, and fine for decorative purposes; *Arthropodium cirrhatum*, grassy tufts with white *Ixia*-like flowers; and the broad-leaved *Crinum latifolium* with large white flowers, and sweetly scented. Of Cape Pelargoniums *P. tricolor*, with white and purple flowers, dabbled black, was very striking; *P. sanguinea*, with beautiful red flowers; *P. glauca*, bright, shining, distinct foliage and white flowers; *P. apiifolium*, finely cut Parsley-like leaves, and white and red flowers—very pretty, and would make a useful small decorative plant; *P. fragrans* having very pretty white flowers and delicately scented. *Oxalis carnosa*, very pretty from the profusion of yellow flowers.

In the stoves were *Eranthemum Cooperi* with pretty foliage, *Ophiocaulon cissampeloides*, a fine creeper, having green flowers and variegated foliage; *Peperomia resedæflora*, having fine Mignonette-like spikes of flowers, white and very fragrant; *Scutellaria violacea robusta*, sky-blue heads of flowers, contrasting finely with *S. Mocciniana* (scarlet); *Eranthemum tuberculatum*, with tube-like white flowers, very fine; *Pavonia multiflora*, having terminal corymbs of flowers, bracteoles

bright red, corolla dark purple, stamens protruding and bearing bright blue anthers, and very floriferous—very fine; *Clerodendron fallax*, a grand old plant with large bright red heads of bloom, less seen than its merits deserve; *Licuala horrida*, a Palm with windmill sail-like leaves, very distinct, and would make a fine table plant when in a small state. *Erythrina marmorata* may be mentioned as suitable for table decoration in a small state and decorative purposes generally, being effectively blotched and spotted with white. *Phyllotænium Lindenii*, an Arad with white variegation; fine for decoration. *Dioscorea melanoleuca*, a handsome-foliaged climber, as silvery as possible, contrasting well with *Cissus discolor*. *Stove Aquatics*.—*Victoria regia* with leaves only, apparently very healthy; *Limnœcharis Humboldti*, with floating leaves and star-like yellow flowers; *Nymphœa cœrulea*, with fine azure blue flowers; the curious and very pretty floating *Azolla pinnata*; *Herpestis reflexa*, with foliage as finely divided as *Asparagus*; the singular *Pistia stratioides*, and *Eichornia azurea*, a trailing aquatic.—G. ABBEY.

THINNING GRAPES.

A FEW remarks on this tedious but very important operation, which is now necessary with unforced Grapes, may be of service to the inexperienced. Unless thinned the berries are usually much too crowded to attain a good size, and the sooner it is done after the berries are nearly as large as peas the better. The long-pointed Grape scissors should be employed, and also a small clean stick, with which to turn and hold the bunches in a convenient position for thinning. As a rule the berries are arranged in triplets, the central berry being the largest. This only, in most instances, should be retained if large berries are desired; the remainder, including all that have an inward tendency, should be removed, the aim being to keep the bunches as open as possible without actual looseness. Insufficient thinning is one of the primary causes of bad keeping. Bunches not required to hang any length of time, and which may be destined to be packed for travelling, however, should not be thinned too freely, as firm bunches travel much the best. Such close-blooming and free-setting varieties as Black Alicante, Lady Downe's, and Foster's Seedling especially require careful thinnings, as the footstalks are very stiff, and the berries remain exactly as originally disposed; but the Black Hamburg and Buckland Sweetwater, having longer and not such stiff footstalks, will yield considerably, and if thinned accordingly may be depended upon, as the berries swell to a certain extent, to fill up any irregularities there may be. The Muscat of Alexandria should not be thinned till it is seen whether they have really set, as those berries that are stoneless will not swell much beyond the size of peas, and should be taken out. Loose shoulders of any kind may either be shortened-in or neatly slung up with matting into a horizontal position. Employ clean scissors, and carefully guard against rubbing the retained berries, or a blemish will be the consequence.—W. IGGULDEN.

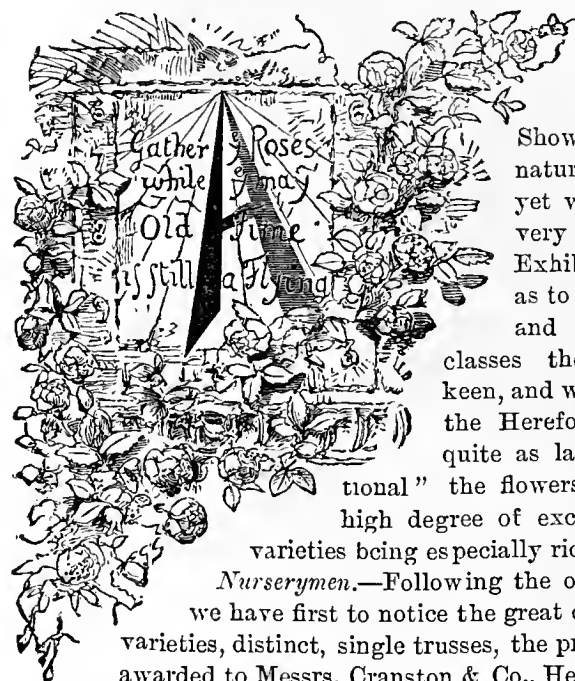

ROSES BOUQUET D'OR AND MADAME BERARD.

THESE two Roses, the former of which is classed as a Noisette and the latter as a Tea, have more than one point of similarity, for in addition to a likeness in colour both are vigorous growers. Where most of the newly budded standard Teas and Noisettes (Gloire de Dijon being of course a notable exception) and many of the H.P.'s succumbed to the frosts of last winter, and even the old wood of some of the summer Roses perished, nearly the whole of the budded and cut-back plants of Bouquet d'Or and Madame Berard withstood a temperature below zero quite unprotected and even better than Gloire de Dijon. When more known I anticipate that the two former will be as largely grown as the latter is. Of the other Teas and Noisettes every bud of Cloth of Gold has disappeared, and a solitary standard of Maréchal Niel only survived, although both were enveloped in pea haulm. All the old dwarfs of Maréchal Niel, too, are very much injured and the growth very weak. On the other hand, of those quite unprotected many buds of Souvenir d'un Ami have put forth, although late in doing so, and most of the old dwarfs are not materially injured. All the buds and the slightly protected dwarfs of Marie Van Houtte are gone, but a few of La Boule d'Or, Madame Bravy, Alba Rosea, and Madame H. Jamain have survived. If raisers will take Bouquet d'Or, Madame Berard, and even Souvenir d'un Ami and Madame Bravy, in hand we may expect to get a race of Teas and Noisettes quite as hardy as the average of the H.P.'s. Do any of your readers know the parentage of Bouquet d'Or and Madame

Berard? I suspect both have the blood of Gloire de Dijon in them.—T. LAXTON, Bedford.

ALEXANDRA PALACE ROSE SHOW.

JULY 10TH.

ALTHOUGH the weather during the week preceding this Show was of a stormy nature in many districts, yet we have to record a very fine and satisfactory Exhibition. The fixture as to date was fortunate, and in nearly all the classes the competition was keen, and with the exception of the Hereford Roses not being quite as large as at the "National" the flowers were mostly of a high degree of excellency, the darker varieties being especially rich in colour.

Nurserymen.—Following the order of the schedule we have first to notice the great class for seventy-two varieties, distinct, single trusses, the premier position being awarded to Messrs. Cranston & Co., Hereford, whose collection of flowers were mostly fresh and well finished. Messrs. Paul and Son, Cheshunt, were second with a fine selection of varieties, but the majority of their blooms though beautifully fresh and of good form were somewhat small. Messrs. Keynes & Co., Salisbury, occupied the third position, and Mr. G. W. Piper, Uckfield, the fourth. There were five competitors in this great class.

For forty-eight triplets there was a very close competition between five exhibitors. Messrs. Paul & Son were placed first with a good collection, Messrs. Cranston & Co. running them very closely for second honours; so close indeed were these two collections, that had the decision of the Judges been reversed no one could have complained. Mr. Turner, Slough, was third, and Messrs. Keynes & Co. fourth. In the class for twenty-four Roses, Hybrid Perpetuals only, three trusses of each, Mr. Turner was first with a fresh and bright collection, including *Senateur Vaisse* very good. Messrs. Cranston and Co. were second with particularly fine examples of *Marie Baumann*, *Louis Van Houtte*, and *Horace Vernet*. Mr. G. W. Piper and Messrs. Paul and Son were third and fourth respectively with fair blooms.

The competition was especially keen in the class for twenty-five Roses, single trusses, several admirable collections being exhibited. Messrs. Cranston & Co. occupied the premier position. Messrs. Turner, Slough, and Prince, Oxford, were so evenly matched that the Judges awarded them equal second prizes. Mr. E. P. Francis, Herts, was placed third, and Mr. John House, Peterborough, fourth, all exhibiting well. For twelve Tea and Noisette Roses Mr. Prince was well to the front with *Elise Vardon*, *Devoniensis*, *Madame Margottin*, *Madame Berard*, *Alba Rosea*, *Caroline Kuster*, *Perle des Jardins*, *Souvenir d'un Ami*, *Innocente Pirola*, *Marie Van Houtte*, *Anna Ollivier*, and *Unique*. Messrs. Paul & Son were awarded the second honours, Messrs. Cranston & Co. third, and Messrs. Keynes & Co. the fourth.

Amateurs.—For forty-eight varieties, single trusses, there were only three competitors. Mr. T. Jowitt, The Old Weir Hereford, won the premier award with a highly meritorious collection, not large blooms, but very evenly matched, and comprising *Marie Baumann*, *François Michelin*, *Madame C. Wood*, *Comtesse de Sereyne*, *Charles Lefebvre*, *Hippolyte Jamain*, *Ferdinand de Lesseps*, *Marie Cointet*, *Abel Carrière*, *Dupuy Jamain*, *Jean Liabaud*, *Prince Arthur*, *Marie Finger*, *John Stuart Mill*, *Capitaine Christy*, *Maurice Bernardin*, *Duchesse de Caylus*, *Lonise Wood*, *Emilie Hausburg*, *Dr. Du Chalus*, *La France*, *Marquise de Castellane*, *Baron Bonstetten*, *Baronne de Rothschild*, *Thomas Mills*, *Pitord*, *Duchesse de Vallombrosa*, *Marie Rady*, *Souvenir d'Auguste Rivière*, *Madame Lacharme*, *Duke of Wellington*, *Monsieur Noman*, *Alfred Colomb*, *Comtesse d'Oxford*, *Reynolds Hole*, *Beauty of Waltham*, *Elie Morel*, *Louis Van Houtte*, *Madame Hippolyte Jamain*, *Dr. Andry*, *Mlle. Eugénie Verdier*, *Monsieur Boncenne*, *Victor Verdier*, *Madame Sophie Fropot*, *Maurice Bernardin*, and *Etienne Levet*. Mr. T. Hollingworth, Maidstone, was a very good second, and Mr. J. Davies, Salisbury, third. The class for thirty-six varieties was better represented both in the number of the competitors and quality of the exhibits, Mr. T. Jowitt again occupying the premier position with a collection of fresh, even, and bright-coloured blooms. Mr. C. Davies, Banbury, was an excellent second; Mr. J. Davies, Salisbury, third;

and Mr. T. Hollingworth fourth. For twenty-four Roses, three trusses of each, Mr. C. Davies was a good first with fine examples of Charles Lefebvre and others.

Ten collections were staged in the class for twenty-four single trusses. Mr. G. Soames, Bourne, was an excellent first, having Etienne Levet, good; Marguerite de St. Amand, Charles Lefebvre, Marguerite Brassac—in fact the whole of the collection were charming examples, fresh and bright. Mr. Hawtrej, Slough, was awarded second honours for a very good collection. Mr. Wakeley, Rainham, and Mr. Sharp, Horsham, were placed equal third, while Mr. Harrington, Essex, occupied the fourth position. The class for twelve single trusses was remarkably well filled. There were twelve competitors. Mr. Pemberton, Havering-atte-Bower, exhibited a very fine collection, and was deservedly awarded the first prize. Mr. Mawley, Croydon, was a very excellent second with an even collection; Mr. Soames third; and the Rev. Alan Cheales, Surrey, fourth, with smaller but neat blooms. In the class for twelve Tea-scented or Noisette (amateurs) there were six competitors. Mr. Hawtrej was a very good first with Amazon, Rubens, Caroline Kuster, Marie Van Houtte, Madame Willermoz, Catherine Mermet, Alba Rosea, Souvenir de Paul Neyron, Madame Lambert, Souvenir d'Elise, and two others. Mr. C. Davies, who was placed second, had, amongst others, good blooms of Bouquet d'Or, Souvenir d'un Ami, Caroline Kuster, and Marie Van Houtte. Mr. W. Harrington and Mr. J. Hollingworth received the other two awards.

The classes for new Roses are always interesting to the connoisseur of Roses. It is there he can readily form opinions between the newer introductions and those varieties he is already familiar with. Messrs. Paul & Son and Mr. Turner held the chief positions, both being placed equal first. Messrs. Pauls' collection consisted of Marquis of Salisbury, deep rose with crimson shading; Madame Amelie Baltet, light satiny rose with silvery shade; Paul Jamain, bright red; Dr. Hogg, deep violet; Comtesse de Choiseuil, bright cherry red; Claude Bernard, deep rose; Duke of Teck, bright crimson-scarlet; Charles Darwin, rich crimson; A. K. Williams, a beautiful imbricated flower, bright red; Madame Alphonse Lavallée, a good Rose of the Marie Baumann type; Souvenir d'Auguste Rivière, crimson-maroon; and Constantin Tretiakoff, cherry red. Mr. Turner's collection comprised Duchess of Bedford, light crimson; Beauty of Stapleford, pale rose; Gaston Levêque, crimson; Countess of Rosebery, carmine; Charles Darwin, Mrs. Harry Turner, deep velvety crimson; Madame Lambert (Tea), rich creamy yellow; Egeria, silvery peach; Wilhelm Keile, bright red; M. Alex. Bernaix, A. K. Williams, and Mdlle. Marie Verdier. Messrs. Keynes & Co. were placed second, and Mr. G. W. Piper third; each of their stands contained many of the varieties named in the above collections. In the class for six trusses of any Rose of 1878, 1879, or 1880 Messrs. Paul & Son gained the first place with A. K. Williams, and Mr. Turner the second place with Charles Darwin. For eighteen English-raised Roses in commerce Mr. Turner exhibited a good collection of the following varieties:—Star of Waltham, Lord Clyde, Lord Macaulay, Royal Standard, Beauty of Waltham, Duchess of Bedford, Magna Charta, Duke of Edinburgh, John Stuart Mill, Miss Poole, Dean of Windsor, Prince Arthur, Princess Beatrice, Charles Darwin, Oxonian, John Hopper, and Sir Garnet Wolseley, and was awarded the first prize. Messrs. Paul & Son were second, and staged, in addition to some varieties in the foregoing collection, The Shah, Duke of Teck, John Bright, Harrison Weir, Duke of Connaught, Reynolds Hole, and May Quennell. Mr. Piper received the third prize. In the class for twelve varieties Messrs. Paul, Piper, and Turner were placed in the order of their names. These classes for English-raised Roses were very interesting, clearly exhibiting that Roses raised on this side of the Channel are in no way inferior to the French-raised Roses; in fact many of them are superior, the majority of them being indispensable even in the smallest collections. Messrs. Cranston and Keynes were awarded the prizes for trusses of Baronne de Rothschild; Mr. J. Wakeley and Messrs. Cranston for La France; Mr. Prince and Messrs. Cranston & Co. for Marie Baumann, in the order of their names in each of their respective classes.

Messrs. W. Paul & Son occupy the whole of two sides of two long tables running through the centre transept of the Palace with cut blooms of Roses representing almost every known variety, and said to contain no less than 1500 Roses, which supply he intends to maintain until Friday night next. In this gigantic collection we noticed A. K. Williams, and the best of the exhibition varieties of the Teas, Catherine Mermet, Isabella Sprant, &c., quantities of the pure white Madame Plantier, many varieties of Moss, in fact almost every distinguishable variety of both summer and autumn flowering Roses. Two first-class certificates were also awarded to this firm for H.P. *Pride of Waltham*, a variety resembling Mdlle. Eugénie Verdier or Marie Finger; for H.P. *Lady Sheffield*, a variety with the form and substance of Star of Waltham and the colour of François Michelin. Mr. Cannell exhibited collections of both double and single Zonal Pelargoniums and Verbenas which found a host of admirers, while Mr. Boller displayed a large collection of Cacti.

The entire Exhibition was well and pleasingly arranged by Mr. Forsyth Johnson and Mr. Cooke. Everything that could be done to facilitate the work of both staging and judging was admirably studied. We append the following notes of this Show by an experienced rosarian.

New brooms sweep clean. The change of administration has made the Palace a much more pleasant place for exhibitors. No more

relegating to an upstairs dining-room; the queen of flowers had the best of everything, and held her court in the large transept. Twenty thousand Roses were promised to an expectant public, and what with exhibition boxes in central lines, and Mr. W. Paul's beautiful background of Roses, almost endless on mossy banks, something like that number may have been attained to. At any rate this July 10th, I suppose, has seen the largest number of Roses ever brought together in England. Some, it is needless to say, were of high quality, and their less highly cultivated brethren were hardly less lovely. It certainly was an exceedingly pretty sight that central hall with its "twenty thousand Roses."

But the Rose Show? That, doubtless, is duly reported on. I shall merely mention some of my own impressions. The Teas were hardly up to the mark, they have not been this year anywhere. The best box I have seen this year was that of Mr. Prince of Oxford, which obtained the first prize. It contained amongst others a Souvenir d'Elise which would have gone far to dethrone the premier Tea of the Crystal Palace.

The new Roses, and the newest, were especially interesting. A triplet of Madame G. Luizet fully sustained the high character of that most lovely Rose. Its soft silvery rose, the colour and the polish of the most delicate light pink coral, make it, I consider, almost first of the Roses of 1879. Charles Darwin, Dr. Hogg, Countess of Rosebery, and Duchess of Bedford were all there to make good their rapidly rising reputation. Mr. Bennett's seedlings have now been exhibited often enough, specially by Mr. Prince, to make them tolerably well known. I have found both colour and substance in the two I have bloomed successfully, W. Saunders and Beauty of Stapleford, and the others seem to be rapidly making themselves a reputation. An interesting feature in the schedule was the class of English-raised Roses, in which Mr. Piper of Uckfield (a name rapidly coming to the front) made a good second to Mr. George Paul. But the newest of the new? These were notably Alexander Mackenzie of Mr. Turner's, a promising colour; and Mr. George Paul's two—Brightness of Cheshunt, which was a burning red spot even amongst all the light reds, but which is not absolutely promised to commerce, its originator being not quite satisfied yet as to substance; and another seedling which came under notice some two years ago when Lady Darnley was visiting Cheshunt. The dedication was offered and accepted, and in 1881 a very lovely Rose of an unusual and pleasing colour may be expected to be introduced to us, and come out as "the Countess of Darnley."

The rain was pouring down and the people pouring in as I left the Palace. I trust that the eager Rose world of north London took full advantage of the banquet of sight and scent prepared for them.—A. C.

HORSHAM ROSE SHOW.

THIS Show, having been postponed from June 29th, took place on July 7th amidst torrents of rain. It was not largely attended by visitors, but the exhibits were many, and the Roses for the most part of excellent quality. Horsham, with a liberality worthy of imitation, has always had open classes with good money prizes. This alone would attract good boxes. The Society is also strong in itself. The fact that it was found necessary to give two extras in two classes, as well as the number of boxes staged, will show how close the competition was in some instances. The silver medal of the N.R.S. for the best box of twelve in the Show was taken by J. B. Haywood, Esq., of Reigate. The prize medal for the best Rose in the room was gained by a magnificent Annie Wood (Rev. J. C. Cox Hales). A Marie Baumann (Haywood) and Louis Van Houtte (Sharp) were also very admirable. The Roses were much set off by rows of foliage plants tastefully arranged between the boxes, the whole under the able management of W. H. Saddler, Esq., Hon. Sec. First prizes were taken in the Association classes for eighteen and twelve varieties by T. Gravely, Esq., and J. B. Haywood, Esq.; for twelve Teas by Mr. A. Slaughter; and for six of the same kind by C. T. Cuthill, Esq., with a beautiful box of Marie Baumann. In the classes open to all England, twenty-four varieties, six boxes were staged, the awards being as follows—first, W. G. Sharp, Esq.; second, Mr. Prince, Oxford; third, Messrs. Mitchell, Piltown. In the class for twelve varieties ten boxes were staged, the Rev. A. Cheales securing the premier position; Mr. Piper, Uckfield, second; and J. B. Haywood, Esq., third; extra prizes being adjudged to Messrs. Prince and Slaughter. Twelve trusses, two varieties light and dark, open to all amateurs, offered by R. Ramsden, Esq.—First, Rev. A. Cheales with La France and Pierre Notting; second, T. Gravely, Esq., with Fisher Holmes and Baronne de Rothschild. Twelve of the same kind, first Messrs. Piper with a box of wonderfully even blooms of Paul Verdier.—B.

ÆNOTHERA BISTORTA VEITCHII.—This is a beautiful little yellow dwarf annual that handsomely peeps out in the shrubbery or herbaceous border from between green foliage, the soft yellow colour contrasting with almost any other. The flower is much smaller than *Æ. macrocarpa*, but many would think this a commendation. I find it most floriferous when the soil is somewhat dry, sandy, and "poorish," meaning not too much so. When the question now is constantly asked, What herbaceous plants can I readily grow? I would like to say a word for the Evening Prim-

rose family, not the least desirable of which I consider this little favourite. The cheapness of many of those hardy annuals I am afraid makes them less appreciated than they deserve.—W. J. M., *Clonmel*.

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S SUMMER SHOW.—JULY 7TH.

NOTWITHSTANDING the fact of the Council allocating the largest share of the prizes to their spring and autumn meetings, the Exhibition held in the Waverley Market, Edinburgh, on the above date compared favourably with the shows of those more highly favoured seasons. The vast market was quite as well filled as usual, the nurserymen of Edinburgh and neighbourhood helping greatly in the furnishing thereof. The Lawson Seed and Nursery Company had, as has been their practice at previous shows, quite a garden of several large beds formed at the west end of the building. Most of the beds were filled with dwarf Coniferae and shrubs of a similar nature in pots, the large centre bed, however, being laid out in a gayer fashion and arranged altogether with much taste. Large Humeas, Palms, &c., were lightly dotted over the main portion of the bed, a groundwork being furnished with plants of a decorative size, consisting of Zonal Pelargoniums, Heliotropes, &c., a broad margin of the same class of plants finishing off the outer edges. The Messrs. Ireland and Thomson, Craigleith Nurseries, exhibited a table of decorative stove plants, such as the newer Crotons, Dracaenas, Bertolonias, Marantas, &c., interspersed with Roses in pots, Begonias, and other flowering plants, also a number of fine cut Roses, a good collection of Delphiniums in variety, English Irises, and other hardy cut flowers. Mr. Robertson Munro of Piershill had a table as usual devoted entirely to new or rare hardy flowers. Noticeable were such as *Androsace chamaejasme*, *Asperula cynanchica*, the small *Campanula hederacea*, and *Pentstemon heterophylla*. Messrs. T. Methven & Sons, Leith Walk, furnished a large table mainly with a bright lot of the best decorative Pelargoniums and Begonias. Underneath, the front of the staging was filled with East Lothian Stocks and various Ferns intermixed, the whole being edged with a line of *Selaginella Kraussiana*. Close to these Messrs. Downie & Laird, West Coates, presented an arrangement which had for its back line a large display of fine Palms and Tree Ferns, the front being filled-in with a miscellaneous collection of ordinary decorative plants. Splendid collections of cut *Pyrethrum* blooms, Pansies, and Violas, with spikes of *Delphinium* in large variety, and some two or three dozen varieties of early-flowering *Phloxes*, added greatly to the general effect of this table. Somewhat similar and even more effective was the table of Messrs. Dickson and Co., Waterloo Place. The centre of this table had some tall well-grown Tree Ferns, in front of and underneath which choice stove and greenhouse plants were effectively arranged. All round the outer margin of the table were placed stands of such plants as *Mimulus* seedlings of a large and fine strain, seedling double *Potentillas* in great variety of colour, a large boxful of cutting Pinks, including such good sorts as Napoleon III., White Queen, Robusta, the common Pink, white Mulc Pinks, &c., large collections of bedding Violas both seedlings and named sorts in all shades of possible colours, Show and Fancy Pansies, with cut blooms of English Iris, &c. But the unique table in the Exhibition was doubtless that furnished from the Royal Botanic Gardens, Inverleith Row. This consisted in the main of *Nepenthes*, *Droseras*, *Sarracenias*, and other insectivorous plants. Especially remarkable were *Nepenthes Hookeriana*, *N. Sedeni*, *N. zeylanica rubra*, *N. hybrida maculata*; *Sarracenia flava*, *purpurea*, *Chelsoni*, *Drummondii*, and *variolaris*; *Darlingtonia californica* with large seed pods; *Cephalotis follicularis*, and *Dionaea muscipula*; *Drosera spatulata* and *dichotoma*, both in flower; and the allied *Drosophyllum lusitanicum*. Amongst Orchids were various *Stanhopeas*, and a large panful of *Disa grandiflora* with sixteen spikes. There was also a good plant of the rare *Agave Victoria Regina*. Of *Trichomanes reniforme* and other Filmy Ferns. New alpine plants were represented by *Gentiana ornata*, *Dianthus eximius*, a cross between *D. alpinus* and *D. deltoides*—a fine rock plant.

Turning now to the more prominent classes in the gardeners' section some large and well-flowered specimens were noted in the first-prize collections of stove and greenhouse plants exhibited by Mr. John Paterson, Millbank, his specimens of *Erica ventricosa alba*, *Aphelexis spectabilis*, and *Dracophyllum gracile* being especially large and fine. Mr. Paterson and Mr. J. Reed, Canaan Bank, also staged good collections of foliage plants. The class for the best table of plants 20 feet by 5 feet was chiefly remarkable by the first-prize contribution of Mr. Spence, Oswald Road, containing a mass of *Cattleya Mossiae* nearly 4 feet across, and having over fifty blooms open. The Orchids did not form a large display; Mr. McGregor, gardener to C. Walker, Esq., Braxfield, Lanark, taking the first prizes for one and two Orchids respectively with a large piece of *Odontoglossum Alexandrae* with three long spikes, and a six-spiked piece of the above, and a good example of *O. vexillarium*. For six exotic Ferns Mr. Paul, Gilmore Place, occupied the leading position with three grand and healthy *Gleichenias*, good plants of *Adiantum Flemingii* and

Williamsii, and a large plant of *Microlepia hirta cristata*. Many tables were bright with *Petunias*, *Gloxinias*, *Carnations*, &c.

Roses.—The centre of attraction was those staged by Mr. Hugh Dickson, Belfast, in the nurserymen's class for thirty-six and eighteen buds respectively, and for which he was awarded first prizes. The most noteworthy blooms in these stands were Constantin Tretiakoff, Pierre Canot, Paul Jamain, Marie Finger, Elie Morel, Marie Baumann, Duchesse de Vallombrosa, Prince of Wales, Antoine Ducher, François Michelin, Beauty of Waltham, La France, Duke of Wellington, Ovid, Carrière, and La Coquette (Hybrid Tea). In both classes Mr. Smith, Stranraer, occupied the second position with stands of very good blooms, but lacking the freshness and vigour of the Belfast champions. In the classes devoted to gardeners no noteworthy collections were staged, the Tea Roses being more especially deficient.

The Fruit classes were especially well filled as a rule, the number of bunches of Grapes staged being very much above the average of the summer shows. For a collection of six dishes of fruit, distinct, Mr. Johnston, gardener to Earl Strathmore, Glamis Castle, and Mr. McKelvie, gardener to the Duke of Roxburgh, Broxmouth Park, alone staged collections, the prizes going in the order named. Mr. Johnston's stands contained good Grapes, Melon, Brown Turkey Figs, large Sulhampstead Peaches, Elruge Nectarines, and Vicomtesse de Thury Strawberries. Mr. Boyd, gardener to W. Forbes, Esq., Callander Park, Falkirk, and Mr. McKinnon, gardener to Viscount Melville, Melville Castle, were first and second respectively for Black Hamburgs, both very fine; Mr. Boyd was also first with grand Muscat Hamburgs, for any other black Grapes Mr. McKinnon being second. The only good white Grapes were from Mr. Mac-onachie, The Gardens, Alexandria, the sort being Buckland Sweet-water, and extra fine. Mr. Boyd was deservedly awarded a special prize for four fine bunches of Grapes consisting of Black Hamburg, Pope's Hamburg, Frankenthal, and Muscat Hamburg. The best Peaches were from Mr. Johnston; the best Nectarines from Mr. McKelvie, very fine; the best Melon from Mr. R. P. Brotherston, gardener to the Earl of Haddington, Tynninghame; the best four dishes of Strawberries from Mr. J. Young, gardener to Earl of Breadalbane, Taymouth Castle; the best single dish from Mr. Corsac, Linlithgow; Mr. Anderson, gardener to Earl of Stair, Oxenford, being first for Figs.

Vegetables were largely represented, as many as nine collections being staged. The judging of these was not very satisfactory, Mr. G. Potter, gardener to W. Laidlay, Esq., Seacliff, being first with collection.

Certificates were granted to Mr. H. Dickson, Belfast, for *Begonia Dicksonii*; to Mr. Gray, Eglington Castle, for *Viola alba compacta*; to Mr. John Mackenzie for white *Petunia Countess of Rosebery*; and to Mr. John Wright, Prestonpans, for a seedling Gooseberry. Mr. Anderson, nurseryman, Meadowbank, had a special prize awarded for a small collection of Orchids, and Mr. Paul, Paisley, a similar award for a fine collection of cut Pinks.

NEW AND CHOICE PLANTS.—No. 2.

CONTINUING my remarks from page 354 of the last volume I select the following as especially worthy of notice:—

HIBISCUS SCHIZOPETALUS (Veitch).—This plant is regarded by the authorities as a variety of the well-known *H. rosa sinensis*, but it is so remarkably distinct in general appearance that few ordinary observers would consider it as so nearly related to that species. The flowers are pendulous on slender peduncles, the petals being deeply cut or lacinated somewhat in the style of the Clarkias. The united filaments of the stamens closely surround the style, and the latter projects about 2 inches beyond the corolla, terminating in five divisions. The colour of the petals is a brilliant orange red; and although the flowers, like those of other Hibiscuses, are of short duration, yet the plant is both attractive and interesting. It is a native of east tropical Africa, where it was found by the Rev. J. A. Lamb, from whom Messrs. Veitch obtained their plants. It was exhibited at one of the Royal Horticultural Society's meetings early in the present year, and was honoured with a first-class certificate. It requires similar culture to its congener. [For the engraving of this plant on the opposite page we are indebted to Messrs. Veitch.]

ANTHURIUM ANDREANUM (Linden).—On April the 13th last a specimen of this remarkable Anthurium from M. Linden's nursery, Ghent, was exhibited at the Royal Horticultural Society's meeting and attracted considerable attention, as it did when first exhibited at Ghent on the 4th of that month. Of a large genus it is undoubtedly one of the most distinct species, and while of great interest to the botanist it also deserves the attention of those who appreciate ornamental qualities more than mere peculiarities of structure. It is a native of Colombia, where M. André (after whom it is named) first discovered plants growing in an epiphytal manner on some Ficus in the State of Cauca. That was in 1876, and about forty plants were despatched to Europe, and in the following year further supplies of the plant were obtained and forwarded to France, these being secured by M. Linden in 1878. The chief peculiarity of the plants is in the spathes, which are

strangely puckered or eorrugated; neither of those terms, however, adequately describing the appearance, and the botanical appellation, "bullated" referring to the inflated surface of a Savoy leaf is perhaps the most suited, except that the indentures are downwards instead of upwards. The colour is a brilliant scarlet shade with a slight tinge of orange, and of a singular shining appearance, as though the surface had been highly polished. The

spathes are large, some being 5 inches in length by 4 in width, and the spadices contrast very strikingly with the brilliant body colour, for they are white at the lower part and greenish yellow towards the apex. The plant is tufted in habit, with dark green narrow leaves, but is undoubtedly inferior to its ally *A. Schertzerianum* in floriferousness. This novelty has been advertised at twenty guineas a plant, but the two hundred specimens that Mr.

Fig. 12.—*HIBISCUS SCHIZOPETALUS*. (See page 46.)

F. C. Lehmann brought to England a short time since were sold at Messrs. Stevens' Auction Rooms, Covent Garden, and realised from two to seven guineas each, thus considerably reducing the original value. The culture that is likely to prove successful is indicated by the facts that the species inhabits an extremely warm and moist district even for the tropics, and is found growing both epiphytally and in damp positions among Mosses.

OLEOBACHIA PALUSTRIS (Williams).—This is an elegant plant, and will probably become popular for decorative purposes. It resembles some of the most graceful Aralias in habit and foliage, but nevertheless it possesses quite a distinct character of its own. The leaves consist of six or seven narrow leaflets arranged in a digitate manner, their colour being a rich dark green, with a midrib of a paler hue. It is of free growth, and may be successfully

grown with ordinary greenhouse plants—a considerable advantage, for being thus grown in a cool temperature it will endure much more exposure than the tender inhabitants of the stove.—R. L.

WEST KENT HORTICULTURAL SOCIETY.

JULY 10TH.

ONE of the largest and most attractive Exhibitions this prosperous and active Society has produced was held on Saturday last in Camden Park, Chislehurst, which was kindly placed at the disposal of the Society by N. W. J. Strode, Esq. A more interesting and beautiful situation for a flower show could scarcely be desired, and, as if determined to render the display worthy of its position and surroundings, exhibitors came forward in large numbers, contributing plants, flowers, fruit, and vegetables of excellent quality generally, and sufficient to fill four large marquees. The nurserymen's collections, as usual, constituted an important feature of the Show, for most of the chief metropolitan firms were represented by large and handsome groups of plants. Amateurs also exhibited plants numerous and well, a most satisfactory vigour and freshness marking their contributions. Fruit and vegetables were staged in good form, the latter being particularly noteworthy for their excellent condition. The majority of the eighty-seven classes enumerated in the schedule were represented by several collections in the divisions respectively devoted to any exhibitor, to amateurs of West Kent only, and to cottagers. This system of classifying the exhibits is both simple and complete, and far preferable to one adopted at an exhibition we recently attended, where about forty classes were arranged under no less than nine divisions, the qualifications of the exhibitors chiefly resting upon the distance of their residences from the town where the Show was held.

Stove and Greenhouse Plants.—These were fairly well shown by several exhibitors, but the competition was not very keen, nor were the specimens of great size, but neat and fresh. In the open class for twelve Messrs. B. Peed & Son, Norbury Nurseries, Lower Streat-ham, staged the best collection, comprising exceptionally handsome examples of *Lilium auratum* and *Allamanda grandiflora*. J. Scott, jun., Esq., Elmstead (gardener, Mr. J. Mumford), was second with much smaller plants, but in good condition. These were the only two entries with twelve specimens. The premier amateurs' six were from J. Burnaby-Atkins, Esq., Halstead Place, Sevenoaks (gardener, Mr. A. Gibson), and the collection was remarkable for including three *Allamandas*—namely, *A. Brearleyana*, *A. grandiflora*, and *A. Hendersoni*, all in vigorous health and well flowered. Mr. Arbuthnot, Budgen Place, Bexley (gardener, Mr. J. Mitchell), and Capt. Aylward, Crofton Court, Orpington (gardener, Mr. J. Archer), followed with fair plants, the former having a neat *Vinca alba*.

Pelargoniums were not very well represented, the plants being rather deficient in the number of flowers. G. Wythes, Esq., Bickley (gardener, Mr. J. Neighbour), was placed first in the open class for six Show varieties with healthy but small specimens; F. P. Alliston, Esq., Beckenham (gardener, Mr. E. Braybon), following with moderately good plants. Zonals were exhibited by J. Lover, Esq., Shirley Court, Shirley; Mr. Neighbour, and Mr. H. Coppin, The Rose Nursery, Shirley, Croydon, who obtained the prizes in the order named. Mr. Archer had the only collection of six Fancy varieties, and obtained the first prize for new specimens. Messrs. Coppin, Lover, and Neighbour were the exhibitors of six double varieties, the first named staging a fine example of Wonderful.

Tuberous Begonias constituted a brilliant display, several exhibitors staging good collections. Messrs. Neighbour, Braybon, and Mitchell were the prizetakers in the order named, all the plants being well grown and flowering profusely. Gloxinias were also shown in fine condition, the blooms large, the colours bright, and the foliage luxuriant. Mr. Neighbour; J. B. Alston, Esq., Fairfield, Bickley (gardener, Mr. G. Bridger); and G. Phillips, Esq., Elmhurst Lodge, Chislehurst (gardener, Mr. A. Saville) were the successful exhibitors. Achimenes were very neat and well flowered, the best specimens being from Mr. Neighbour, Mr. Bridger, and F. Heritage, Esq., Ladywood, Orpington (gardener, Mr. J. Kent). Fuchsias were shown by Mr. Mitchell, T. A. Mitchell, Esq., The Woodlands, Chislehurst (gardener, Mr. H. Cole), and Mr. Archer, who were awarded the prizes in that order for well-flowered plants of moderate size, an extra prize being awarded to Mr. Braybon.

Fine-foliaged Plants.—In the principal open class for nine distinct varieties and species Mr. Gibson won the chief prize for a handsome *Alocasia metallica*, a neat *A. Lowii*, and several fine *Crotons*, *Dracenas*, and *Palms*. The second and third positions were accorded to W. C. Pickersgill, Esq., Blendon Hall, Bexley (gardener, Mr. Moore), and Mr. Kent, both of whom contributed healthy specimens. There were three competitors in the amateurs' class for six plants—namely, Mr. Saville, Mr. Mitchell, and C. Boosey, Esq., The Pines, Bickley (gardener, Mr. W. Gammon), who gained the prizes with very well grown specimens. *Dracenas* were exhibited by A. Pearce, Esq., Tweedbank, Sevenoaks (gardener, Mr. Talmage), Mr. Gibson, and W. C. Pickersgill, Esq., Blendon Hall, Bexley (gardener, Mr. F. Moore), all the specimens being vigorous and symmetrical. Ornamental-foliaged Begonias were shown by W. Sentance, Esq., Merevale, Bickley (gardener, H. Sawyer), who obtained the chief prize with luxuriant plants bearing well-coloured foliage, Mr. Talmage and Mr. Saville following with nearly equally as good specimens. *Caladiums* were unusually fine both in size and colouring of the foliage,

Messrs. Gammon, Bridger, and Braybon being the successful exhibitors. Ferns were not very numerous, but fresh and healthy. Mr. Neighbour had the best six hardy varieties, being followed by J. Williams, Esq., Blackbrook, Bickley (gardener, Mr. Gearing), and Mr. Cole. Six exotic Ferns were contributed by Messrs. Neighbour, Mitchell, and Gearing staging collections of neat plants, the respective merits of which were recognised by awarding the prizes in the above order. Mr. Gibson had the best single specimen Fern—viz., *Gymnogramma Laucheana* of fair size and very luxuriant. Mr. Betts, Homewood, Bickley, and W. Palmer, Esq., Elmstead Court, Chislehurst (gardener, J. Field), followed, the former with *Adiantum cuneatum*, and the latter with *A. farleyense*. The chief exhibitors of *Selaginellas* were M. Yeatman, Esq., Widmore (gardener, Mr. J. Cooper), who was first with six neat specimens, and Messrs. Neighbour, Talmage, and Cooper.

Cut Flowers.—The principal of these were the Roses, to which several classes were devoted, and a fair display was produced by the numerous exhibits. The most important was the open class for forty-eight triplets, in which Messrs. George Bunyard & Co., Maidstone, were the only exhibitors, gaining the premier award with beautiful blooms of good substance and exceptionally fresh in colour. The same firm was first with twenty-four varieties, being followed by Messrs. J. Laing & Co., Forest Hill, and Mr. Coppin with neat collections. Mr. B. R. Cant's special prizes for twelve single blooms were obtained by T. Burnaby-Atkins, Esq., Rev. J. M. Fuller, The Vicarage, Bexley, and A. Mitchell, Esq., all of whom had fair blooms. Messrs. Bunyard, Laing, and Coppin also carried off the prizes for twelve blooms of one variety, the first and second with Marie Baumann (handsome), and the third with Star of Waltham. The chief prize-takers in the amateurs' classes were T. Burnaby-Atkins, Esq.; Captain Christy, Buckhurst Lodge, Westerham; W. C. Pickersgill, Esq.; the Rev. Fuller; Alexander Potter, Esq., Stoneycroft, Widmore; and Messrs. Talmage, Neighbour, and Cole. For a collection of twelve hardy perennials J. Whitehead, Esq., Southwood, Bickley (gardener, Mr. F. Maynard), was awarded the premier prize. Table decorations were admirably represented, several very tasteful arrangements being contributed.

Fruit.—This was well shown, the chief defect being the unripened condition of most of the Grapes. For a collection of six distinct fruits Mr. Neighbour was first with good examples of black and white Grapes, Peaches, Nectarines, and Melons; J. E. Lovibond, Esq., Start's Hill, Farnborough (gardener, Mr. Tucker), being second with fairly well ripened fruits. Messrs. Neighbour, Tucker, and Mitchell were the chief exhibitors of Grapes; while Strawberries were well shown by Messrs. Maynard, Gammon, and Cooper.

Vegetables were extremely fresh and clean, handsome collections being staged by Messrs. Neighbour, Rollison, and Moore, among many others. The cottagers' productions were also remarkably fine and numerous.

Miscellaneous Exhibits.—Extra prizes were deservedly awarded to the following exhibitors for groups and collections of plants. To Messrs. Veitch & Son, Chelsea, for a handsome group of Orchids and fine-foliage plants; the General Horticultural Company for an attractive and extensive group of *Crotons*, *Dracenas*, and similar plants; to Messrs. John Laing & Co. for a collection of Tuberous Begonias and fine-foliage plants; to Mr. B. S. Williams for an interesting collection of new and beautiful Orchids and stove plants; to Mr. H. Cannell, Swanley, Kent, for one of the most attractive groups in the Exhibition, consisting of *Colenses* and *Delphiniums* edged with Tuberous Begonias, Gloxinias, and Lobelias; to Mr. H. Coppin for a group of Tuberous Begonias; and to several other exhibitors.

The weather in the early part of the afternoon was very unfavourable, several heavy storms of rain occurring, but it eventually became clear and fine, a large number of persons attending the Exhibition.

CAMELLIAS AND AZALEAS.

OBSERVING that there are many inquiries from amateurs respecting these plants, a few brief practical notes may possibly be useful.

CAMELLIAS.—Those planted out and having set their buds must be kept both cooler and drier so as to prevent or lessen the tendency to second growth, as would be likely to result from keeping the house somewhat close and moist for the especial benefit of plants in pots or tubs. The latter in such case must be removed to a house where they can have the necessary treatment to finish their growth and the setting of the buds. This should always be kept in view, as if the buds become too forward for the time when their flowers are required no retarding will keep them back, and, on the other hand, if required early in the autumn they can only be had by corresponding early growth, and under conditions that will bring the flowers on gradually, forcing in the later stages invariably causing the buds to drop. Camellia blooms are now as much valued in autumn and early winter as they are at Christmas and after; indeed in many places they are expected from October to June inclusive, and they can be had with intelligent treatment.

AZALEAS.—Plants that were started early and which are desired to attain a large size as quickly as possible, will now be setting

their buds. These should be pinched out as soon as formed, not deferring it too long or the plants will make very little second growth, which should be encouraged by supplying heat and moisture liberally. The latest-flowered plants should be encouraged to make growth by keeping the house close and moist, and shading with some light material in bright weather only, the plants being kept near the glass and with as much light as they will bear, so as to secure good-textured leaves, which are more persistent than thin foliage. Red spider and thrips must be kept under, or they will soon destroy the appearance of the plants and interfere with the flowering.—G. P.

FLUTE BUDDING.

At this the season for budding Roses and fruit trees the mode represented in fig. 13 may appropriately be submitted. It is often practised in France, and possibly there may be some amateurs who would like to try it in this country. The little cut pretty well explains itself. The bud or scion A is placed on the stock B in place of the portion removed at C, the bud being secured in its position with matting or worsted in the usual manner, and is preferably covered with a mastic, but this is not essential. If the bud is larger than the stock a longitudinal slice will reduce it to the right size. In carrying out the process the work should be done clearly and expeditiously.

Fig. 13.

MAIDSTONE ROSE SHOW.

ALTHOUGH sundry hints had been thrown out that the Maidstone Rose Society was at the point of death, yet with so good a Secretary as Mr. Bensted, and so warm and generous a supporter of the Rose as Mr. Hollingworth, it was not to be expected that the Society which has had to record so many brilliant successes would be allowed to collapse, and this expectation was fulfilled. A considerable amount of energy was put forth, and as a result a most excellent Exhibition was held on Tuesday last the 6th inst. The Exhibition was held in the Concert-room, and attracted not only many good growers but also a considerable number of visitors. The challenge cup for amateurs was won for the third time by Mr. Burnaby-Atkins of Halstead Place, Sevenoaks, with eighteen blooms, he also obtaining the silver medal of the National Rose Society for the best box in the Show. The varieties shown were Etienne Levet, good; Capitaine Christy, Madame Charles Wood, very good; Baronne de Rothschild, Madame Caillat, Marie Baumann, very fine; Charles Lefebvre, good; Annie Wood, La France, a very fine bloom; Auguste Rigotard, Senateur Vaisse, very bright; Henri Ledechaux, Mons. Boncenne, excellent; Marquise de Castellane, Dr. Andry, Mons. E. Y. Teas, very good; and Duke of Edinburgh.

In the class for twelve some excellent stands were staged. Mr. W. Wakeley was first with very fine blooms of Capitaine Christy, Fisher Holmes, Cheshunt Hybrid, Marie Baumann, La France, Duke of Connaught, Thomas Mills, Lord Macaulay, President Grévy, Mdlle. Eugénie Verdier, and Camille Bernardin. The Rev. H. B. Biron ran very close with excellent blooms of Naomi, a very dark flower to which I have already alluded in my account of the Canterbury Show. Capitaine Christy, Xavier Olibo, a magnificent bloom which obtained the bronze medal of the National Rose Society as the best Rose in the Show; E. Y. Teas, Baroness Rothschild, Louis Van Houtte, La France, Marie Baumann, Reynolds Hole, Maréchal Vaillant, Fisher Holmes, and Madame Lacharme. In the class for six Lewis A. Killick, Esq., of Mount Pleasant, Langley, was first with Wilson Saunders, Monsieur Noman, Senateur Vaisse, Duke of Edinburgh, Baroness Rothschild, and John Stuart Mill—a stand of very neat blooms. In the class for twelve Teas or Noisettes Mr. Knight of Sittingbourne was first with Homère, President, Hippolyte Jamain, Marie Van Houtte, Catherine Mermet, &c. Mr. F. Warde was a good second. In the class for six Teas Mr. J. Wakeley of Rainham was first with good blooms of Madame Margottin, Madame Berard, Souvenir d'Elise, Jean Ducher, and M. Cecile Berthod. In the class for twelve blooms, six Teas and six Hybrid Perpetuals, Mr. Warde was first with some excellent blooms of Triomphe de Rennes, Duke of Edinburgh, Star of Waltham, Adrienne Christophle, Maréchal Niel, Robin Hood, Belle Lyonnaise, Madame Berard, Alfred Colomb, &c. In the class for six of any one variety Mr. Wakeley was first with excellent blooms of Alfred Colomb; Mr. J. Wakeley second with La France, very good; Mr. Burnaby-Atkins and the Rev. J. M. Fuller equal third with Etienne Levet and Maréchal Niel.

The borough Members gave a piece of plate as a challenge cup, to be competed for by ladies for a table decoration. This brought out a spirited competition, and the prize was won by Mrs. Biron with a tastefully arrayed stand, in which of course Roses predominated. The fault which marked the same lady's stand at Canterbury had been avoided—too much crowding, and hence her success. The other stands were well arrayed, one especially by Mrs. Killick would have stood a fair chance of taking first instead of third, but the base was

poor, the Roses employed being only buds. There were some excellent button-hole bouquets, the first prize being taken by Mrs. Bensted, the mother of the very excellent and energetic Secretary of the Society, to whom its members are so much indebted for the success of the Exhibition.—D., Deal.

P.S.—With regard to the Rose mentioned above as Naomi I send a letter I have received from the Rev. H. B. Biron who exhibited it:—"Mr. Bunyard of Ashford has satisfactorily cleared up the mystery of my Rose of uncertain name. In the year 1876 he purchased a Rose called Eugène Furst from Soupert et Notting, which exactly answers to the description of Naomi. On his Rose book Naomi, an old pink Rose, stood No. 111. This Rose he ceased to cultivate, and put the new one (Eugène Furst) to Naomi's number. His foreman seeing the No. 111 gave me the name of Naomi with the Rose, and hence my error. The Rose Eugène Furst is described in the French catalogues as follows:—'Fl. tr. gr. pl. bien faite bombée, rouge cramoisie velouté; nuance de pourpre foncé; tres belle.' It threw very small blooms with me at first, but I was so pleased with the colour that I took great pains with it, and it improves yearly, and will I believe come to stand high on the Rose list. I am glad to know the real name. Perhaps the English nurserymen have the Rose; if not they ought to be made aware of its possible excellence."

HARDY FLOWER BORDERS.

THIS has been an unusually good year for gay flower borders with hardy plants; and as some of your correspondents seem at a loss what plants to use for permanently planting on showy borders, the recital of a few items culled from a pretty large practice here may possibly be of use, and is offered accordingly.

For early flowering, after the Crocuses, we rely upon Daisies, Aubrietias, Alyssums, and Cheiranthus, mostly in the front line of the borders, to be followed by Violas. *Doronicum caucasicum* is also a most useful early yellow, and should be largely used in every garden. The larger *Doronicums* come later, and are not so suitable, but are useful for cutting and for back borders. *Trollius europæus*, *T. asiaticus*, and other forms are very beautiful and last a long time in flower. With them can be associated the *Centaureas*, blue, white, and pink, but they are coarse growers, and should be freely cut back as they go out of flower. The next group of flowers still go with the Violas and self Pansies; we use Pinks of the old pink and white selfs very largely, and the old-fashioned mule Pinks. These alternating at every 3 or 4 yards with yellow Violas make a most gay margin, and when backed by clumps of purple and blue Violas and Pansies are very beautiful indeed. In the same bed we have *Pyrethrums*, single and double, red, white, and yellow; *Delphiniums*, both light and dark blue; *Aquilegias*, *Pæonies*, Sweet Williams, Rockets, and many other similar tall-growing flowers, and as these pass we rely upon Roses, *Phloxes*, *Pentstemons*, *Antirrhinums*, *Geums*, and the lovely *Anemone Honorine Jobert*. These flowers will produce a very complete succession throughout the early and late summer, and when bulbs are judiciously intermixed will form a lovely effect at all times. We employ bulbs largely, commencing with the Daffodils, Narcissi, and Tulips, followed by the English and other Irises, and later again by the Lilliums (English and Japanese), and the Gladioli, &c., to any extent. We also rely a good deal upon annuals for autumn bloom, as herbaceous plants are over by the middle of summer, and it is just at this time that annuals are at their best in this district.—BROCKHURST, Didsbury.

NEWCASTLE SUMMER SHOW.

JULY 7TH AND 8TH.

THE Botanical and Horticultural Society of Durham, Northumberland, and Newcastle-on-Tyne held their summer Show in the Leazes Park, Newcastle, on the above date—a place in many ways adapted for an exhibition of such extraordinary magnitude as the Newcastle Flower Show has now grown to. The hitherto almost unprecedented exertions of this Society has been more visible and striking in the present Exhibition than any other of its predecessors. The Committee have offered this year a much better schedule, including classes for groups of miscellaneous plants, which were the most striking features of the late Exhibition. In every class and department of the Show there was a marked improvement from that of last year or the year before, and it was considered by many as one of the best shows held in England this year.

Referring at once to the schedule, we commence with the classes which were open to all. In the chief class a silver cup value £12, and the Royal Horticultural Society's medal, were won by Mr. Cypher, nurseryman, Cheltenham, with some very fine examples of *Ixora Williamsii* 5 and 6 feet, and *regina*, both plants admirably flowered. *Allamandas nobilis* and *grandiflora* were excellent both in colour, size, and freshness of flower. Mr. Cypher had also an excellent *Erica tri-color*, a good *Dracophyllum gracile*, and a very large-spined *Anthurium Schertzerianum*. Mr. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester, was second with plants somewhat

inferior to the first, Mr. Tudgey having been already at most of the prominent exhibitions held this year; his best plants being *Anthurium Schertzerianum*, *Clorodendron Balfourianum*, *Allamanda Hendersoni*; *Erica ferruginea* and *Paxtoni*, the former being a magnificent plant. There were three lots; Mr. Noble, gardener to Theo. Fry, Esq., M.P., Woodburn, Darlington, being third. In the corresponding amateurs' class for six flowering plants Mr. E. W. Letts, gardener to the Earl of Zetland, Upleatham, was first with a very fine collection. He had *Ixora coccinea*, grand, massive in truss, and finely coloured; *Erica ferruginea* and *Bougainvillea glabra* being both extraordinary. Mr. Tudgey was again second; his *Anthurium Schertzerianum*, *Clorodendron Balfourianum*, and *Erica venosa* were the best. In this class there were five competitors.

For eight foliage plants Mr. Cypher took premier honours with fine examples of *Cordyline indivisa*, *Cycas intermedia*, and *Croton Disraeli* very fine. Mr. Niel Black, gardener to Mr. Pease, Southend, Darlington, was second with fine examples of *Croton Johannis* unusually well coloured, and *C. undulatum*. In the class for six foliage plants Mr. Letts was first with very fine examples of *Croton majesticus*, *C. Johannis*, and *Gleichenia rupestris* in splendid condition. This we believe is Mr. Letts's *début* as an exhibitor, and his attempt is very creditable to him. Mr. Tudgey was second with some good plants of *Croton Johannis*, *C. Andreanus*, and *Geonoma gracilis*. There were altogether five collections, none of which would have disgraced any exhibition.

For a group of plants the Society offered £10, space allowed being 20 by 10 feet. There were five entries, and as a new feature at Newcastle formed one of the most distinguished characteristics of the Show. Mr. W. Yule, gardener to W. Pease, Esq., South Pierremont, Darlington, was first with a very fine collection of plants, embracing Palms, Crotons, and flowering plants arranged with taste and judgment. Mr. W. R. Armstrong, nurseryman, Newcastle, was second with very good plants; his centre plant consisted of a huge *Stephanotis* on a large balloon trellis. Mr. Noble was third, his group containing some very fine plants, especially noticeable being a finely coloured specimen of *Croton Johannis*. This was backed up with several other fine plants, but towards the edge the arrangement was a little too heavy.

Pelargoniums for the time of year were in splendid condition, those shown by Mr. May being in prime condition, and by the northern growers were much admired; he had a very fine plant of *Gipsy*. Mr. Lazenby, nurseryman, York, following with another very good lot. In the amateurs' class Mr. Sanderson, gardener to W. H. Parker, Esq., The Elms, was first with fresh examples of *Beadsman*, *British Tar*, and *Wm. Bull*; Mr. Adams, Swallow, following. There were in this class four lots. In the open class for six Fancy varieties Messrs. May and Lazenby took premier honours with very fine plants. For six Zonal Pelargoniums Mr. Wm. Spoor, Swallow, was first; they were very creditable to him, and consisted of such useful varieties as *Mrs. Wm. Paul* and *Master Christine*.

Roses were the only weak feature of the Show. This fact is no doubt due to the circumstance that the Show is quite three weeks too early for the northern exhibitors. The prize of £6 for forty-eight Roses, not less than twenty-four varieties, only secured three entries; Messrs. Cranston & Co. of Hereford being an easy first with what were for the season considered fine blooms of *Exposition de Brie*, *Princess Beatrice*, *Marie Baumann*, *Mdlle. Eugénie Verdier*, *Général Jacqueminot* (splendid), *Baronne de Rothschild*, *Dupuy Jamain*, *Maréchal Niel*, *Madame Thérèse Levet*, *Madame Lacharme*, and *Charles Lefebvre*. For thirty-six Roses, not less than eighteen varieties, no first was awarded, Messrs. Cranston & Co. being placed second. For twelve yellows, R. Mack & Son, nurserymen, Catterick, Yorkshire, were awarded the first prize with some very good blooms. For twelve Roses, Tea-scented, they were also first. In the corresponding class for thirty-six Roses Messrs. Cranston & Co., Hereford, offered a ten-guinea challenge cup to be won twice in three years. T. Jowitt, Esq., The Old Weir, Hereford, was first with handsome blooms. For twenty-four Mr. Jowitt was also first. He had some very fine blooms which were fresh and good, and were much superior to the exhibits of his northern opponents.

Table Decorations.—These formed one of the great features of this Show. The Society offered £10 as the first prize for dinner-table decorations. There were four competitors, including the great International prizetaker, Mr. Cypher of Cheltenham, who had to succumb this time to a successful local exhibitor, Mr. M. Thompson, gardener to Lindsay Wood, Esq., South Hill. The arrangement of his centre-piece elicited from the Judges marked approval, his style being so light and elegant, with just sufficient coloured flowers to give the whole an artistic effect. The flowers he employed in the centre were, in the top of the stand, *Everlastings*, *Oncidiums*, *Water Lilies*, *Gloxinias*, *Ixoras*, and *Dipladenias*. These heavier flowers were placed towards the base. The base of the stand was margined with *Davallia Mooreana*, and the whole was effectively draped with *Lygodium scandens*. Mr. Cypher also had an excellent table, his centre being a fine plant of *Cocos Weddelliana* springing from a bed of *Selaginellas*, with two very well-arranged epergnes. Mr. Methven, gardener to E. Lange, Esq., Heathfield House, Gateshead, and Mrs. Gellender, florist, Grey Street, Newcastle, filled the remaining places with creditable tables. Table plants were also very good. Six lots were shown, Mr. Tudgey being first. Epergnes were very well arranged, Mr. Cypher being first, and Mr. Whiting, gardener to — Walker, Esq., The Shot Tower,

Newcastle. Hand, wedding, and buttonhole bouquets were also numerous. For six foliage plants there were seven competitors, Mr. Letts again securing premier honours. For six exotic Ferns he was also first too with noble specimens of *Davallia Mooreana* 7 feet across; *Cyathea dealbata*, *Dicksonia antarctica*, and *Gleichenia rupestris* (magnificent). Mr. Tudgey was a good second with *Davallia Mooreana* and *Gleichenia rupestris*. Mr. Noble won with six British Ferns, showing fresh plants of *Osmundas*, *Trichomanes*, and *Athyriums*.

Cut flowers of hardy and herbaceous plants were very fine, and many very beautiful varieties were represented. For twenty-four bunches of flowers there were ten entries, Mr. W. Yule being first with a pretty collection of *Delphiniums*, *Thalictrums*, *Spiræas*, *Lychnises*, *Lupins*, *Potentillas*, and *Alstromerias*. Mr. E. Larke, gardener to the Rev. Mr. Wheeler, Whitby Vicarage, was second with a collection which contained some very fine Irises.

FRUIT.—This department has considerably developed since last year both in number of exhibits and quality of produce. For six dishes of fruit the Society offered £5 and the Royal Horticultural Society's bronze medal. There were five competitors; Mr. H. G. Clayton, gardener to J. Fielden, Esq., Grimston Park, Tadcaster, being first with a fine Queen Pine, Muscat of Alexandria and Black Hamburg Grapes, good Royal George Peaches, Eastnor Castle Melon, and President Strawberries, all of which were good. Mr. H. Mann, gardener to Mrs. R. D. Hornsby, St. Vincent's, Grantham, was second, his best dishes being Black Hamburg Grapes and Elruge Nectarines. Mr. J. Edmonds, gardener to the Duke of St. Albans, Bestwood Lodge, Nottingham, was third. For four dishes of fruit, Pines excluded, Mr. E. W. Letts took premier honours with Black Hamburg and Buckland Sweetwater Grapes, Peaches, and a fine Melon, neatly netted, called *Marcellus*. Mr. J. Clark, gardener to the Marquis of Ripon, Studley Royal, was second, staging good Black Hamburg and Golden Champion Grapes. For four bunches of Grapes Mr. Letts was first, there being eight competitors. For two bunches of white Grapes J. Mavin & Son, market gardeners, Whitby, were first; Mr. Hutchinson, gardener to — Hunter, Esq., J.P., Whickham Grange, amongst thirteen competitors, winning first with *Madresfield Court*, which were very fine. A number of Melons were shown, Mr. Yule winning with *William Tillery Melon*. There were ten dishes of Peaches, Mr. Edmonds winning with some noble examples of *Chancellor*. There were also ten dishes of Nectarines, Mr. H. J. Clayton, Mr. Edmonds, and Mr. J. R. Jowsey taking honours respectively. Figs, Cherries, and Strawberries were well shown by Messrs. Clark, Elsworth, and Clark, who took first in each class.

In concluding our remarks on the Show it will be interesting to state that there were admitted on both days 24,830 persons, of whom 19,363 paid at the gates, and 5017 were admitted by ticket. The total receipts at the gates were £678 19s. 8d., as against £519 16s. last year. There were 110 exhibitors, who forwarded 708 Rose blooms, 478 cut flowers, 150 table decorations, bouquets, 196 dishes of fruit, 20 epergnes, 155 specimen plants, 253 Ferns and *Ericas*, and 700 plants in groups, making a total of 3041, as against 1889 in the summer Show of 1879. The Exhibition was held in six large tents with their sides open, forming one large massive pavilion. Several leading nurserymen sent magnificent collections of every novelty of recent introduction, Messrs. Veitch of Chelsea and Williams of the Paradise Nurseries, London, contributing two collections which entirely filled one end of the pavilion. Messrs. J. Robson & Sons, Hexham, sent a fine collection of *Coniferae* and Alpine plants, as also did Mr. Wm. Fell of Hexham. Mr. W. H. Hilton sent some excellent hand-painted flower pots of unbreakable material. Mackenzie & Moncur, horticultural builders, of Edinburgh, exhibited one of their patent conservatories; and Messrs. Dinning & Cooke, hot-water engineers, Newcastle, exhibited their patent hot-water apparatus for heating hothouses, &c.

The Committee and officers in general deserve to be congratulated on the success of their Show, as they spared neither time nor labour to make it what it was—a fine Exhibition.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE thirty-seventh anniversary of this excellent institution was held at the "Albion," Aldersgate Street, on Wednesday evening the 7th inst. H.R.H. the Duke of Connaught presided, and among the company were H.S.H. the Duke of Teek; the Right Hon. Sir F. W. Truscott, Lord Mayor of London; Sir Trevor Lawrence, Bart.; Dr. Hogg; and Messrs. R. Marnock, H. Webb, G. F. Wilson, H. J. Veitch, A. Veitch, C. Lee, J. Lee, R. A. Osborn, J. Fraser, B. S. Williams, W. Bull, and many others. In proposing the toast, "Continued Success and Prosperity to the Gardeners' Royal Benevolent Institution," His Royal Highness referred to the objects of the Society, and commented on the progress which has been made since 1842, after the somewhat unfavourable period which followed the establishment of the Society in 1838 had been passed. He was happy to state that since that time 269 persons had been relieved, and the funds now amount to £12,000. After some further observations on the difficulties and disadvantages gardeners have to contend with, and commending the admirable management of the Society, His Royal Highness concluded by coupling the name of Mr. Robert Wrench with the toast above

indicated. Mr. Wrench the Treasurer responded appropriately, and the Lord Mayor then proposed the health of the Duke of Connaught. In acknowledging the toast His Royal Highness stated he had always taken great interest in horticulture, and it afforded him great pleasure to witness the products of the gardeners' skill as collected at exhibitions.

"The Secretary, Mr. Cutler," being proposed by the Chairman, that gentleman responded, and compared the dinners held at the commencement of the Society, when about £50 were collected, with the one held on that occasion, when the subscription was the largest ever received. His Royal Highness the Duke of Connaught had given them 300 guineas; Mr. H. J. Veitch 259 donors, or £269 2s. 6d.; twelve life members, £126; and 149 annual subscriptions, £158 18s., making a total of £554 0s. 6d.; and through Mr. Tate of Messrs. Brown & Tate, Manchester, they had received the sum of £110. The sum total of the subscriptions amounted to over £1400. The Chairman proposed "The Royal Horticultural Society" and "The Royal Botanic Society," to which the Duke of Teck and Sir Trevor Lawrence replied in appropriate terms. Other toasts were also given and responded to, and the meeting then terminated.

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, G. T. Clarke, Esq., V.P., in the chair, the following candidates were duly elected Fellows:—viz., Mrs. Firman, Francis Henry Hogg, Sidney Howard, Dr. P. Anson, Mrs. Keane, Robinson Kendal, Douglas Kingsford, Rev. H. Dalgety McCheane, J. B. Sharpe, Villiers Stuart, M.P., James Waddell, Charles Westendarp. The Rev. George Henslow afterwards delivered a most interesting lecture on the plants which were exhibited, and for a report of which we regret we have not space.

— THE usual monthly dinner of THE HORTICULTURAL CLUB took place on Tuesday last, when the following gentlemen were elected members—Sir Richard Wallace, Bart., M.P.; Messrs. C. H. Hawtrej, J. P. Hawtrej, E. P. Francis, and E. P. Wollaston.

— MR. T. RICHES of Lower Tooting has sent us umbels of the pretty and useful hardy bulbous plant, *BRODIAEA CONGESTA*. The flowers are of a clear purplish blue tint, and are borne in compact umbels, somewhat in the style of an *Allium*. It is quite hardy, and succeeds in any ordinary light garden soil, and continues in flower for a considerable time.

— IN the old Lily house at Kew a beautiful aquatic plant—namely, *JUSSIEA NATANS*, is now flowering freely. The blooms are large, of a bright yellow colour, and suggestive of some *Oenotheras* in shape and colour.

— "J. U." WRITES in very high terms of praise of the MELON WILLIAM TILLERY, which he considers to be a variety of great excellence in the form, colour, and flavour of the fruit.

— A CORRESPONDENT writes that "*PETROCOPTIS LAGASCÆANA* is one of the best alpine plants I know. It is remarkably floriferous, and continues in flower for a long time, how long I cannot yet say, as this is the first season I have grown it, and it is now as bright as it was six weeks ago. The flowers are rose colour."

— WE have received a very rich collection of spikes of *DELPHINIUMS* grown by Mr. Joseph L. Stevens of Grasmere, Byfleet, Surrey, which illustrate in a remarkable manner the beauty and decorative value of this genus of herbaceous plants. In some instances the flowers are intensely double, others are semi-double, but the great majority are single flowers. The latter are doubtless the most beautiful; the large spreading sepals being of almost every hue of blue, purple, and lilac, approaching

red, and shaded with two and occasionally three shades of colour. In some cases the petals are quite white, forming a clear bright eye in the centre of the flower, in others they too are striped and shaded. We can only say they are very beautiful.

— WE draw the attention of our readers to the fact that the EVENING FETE OF THE ROYAL HORTICULTURAL SOCIETY will be held on Wednesday next the 21st inst., when the Gardens at South Kensington will be illuminated from 8 until 12 P.M. The bands of the Royal Horse Guards (Blues), and the 2nd Life Guards will be in attendance, and should the weather prove favourable the gathering will no doubt prove an extremely brilliant one.

— WE learn from *Nature* that the COLLECTION OF MOSSES of the late Professor Schimper of Strasburg has been purchased by the Baroness Burdett Coutts, who has presented this valuable and well-known collection to the Royal Gardens, Kew.

— AS an example of the way in which WINDOW GARDENING is being encouraged in the great metropolis, we may state that the fourteenth summer Exhibition of a Society instituted for that purpose at Westminster was held last week, and proved very successful, except as regards the weather. The President of the Society is the Dean of Westminster; the patronage of the Duke and Duchess of Northumberland, the Earl and Countess of Pembroke, the Earl and Countess of Brownlow, and the Hon. Alfred Talbot being also generously accorded. Under such powerful support the Society may well be expected to obtain some good results. The prizes were delivered to the winners by the Earl of Shaftesbury.

— A CORRESPONDENT states that the annual Exhibition of the IPSWICH AND EAST OF ENGLAND HORTICULTURAL SOCIETY which was held last week in Christchurch Park, Ipswich, proved very successful as regards the number and quality of the exhibits, notwithstanding the unfavourable weather that prevailed. Plants were well shown, Messrs. J. Gilbert & Son of Ipswich being the principal prizetakers. Cut flowers, particularly Roses, were very good. The special prize for forty-eight distinct varieties offered by Admiral Sir G. N. Broke-Middleton, Bart., was gained by Mr. B. R. Cant, Colchester. Other winners in those classes were Mr. B. F. Cant, Colchester; Rev. H. A. Berners, Harkstead Rectory, Ipswich; Mr. G. L. Rushmore, gardener to Sir Charles Rowley, Tendring Hall, Stoke; and Mr. G. Palmer, gardener to T. H. Powell, Esq., Drinkstone Park, Bury St. Edmunds. Fruit was numerous and well shown, the principal exhibitors being Mr. T. Blair, gardener to Admiral Sir G. N. Broke-Middleton, Bart., Shrubland Park; Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich; and Mr. J. Mill, gardener to Lord Rendlesham, Rendlesham Hall.

— THERE is now a grand display of *NYMPHÆAS* IN THE OXFORD BOTANIC GARDEN, where the tropical aquatics generally are also in excellent condition. Among the species of *Nymphæas* especially noticeable are *N. Cyanea*, *N. odorata*, *N. devoniensis*, *N. Daubeniana*, and *N. Lotus rosea*; but many others are also well represented, for the Oxford collection is a remarkably fine one.

— IN the same house the charming *EICHORNIA AZUREA* is flowering most profusely, and thriving as well as could be desired. This plant, it will be remembered, flowered last year at the Regent's Park Botanic Gardens, whence it was distributed to both Kew and Oxford, and strangely enough the latter was the only place where they succeeded in preserving it through the winter.

— WE have received the following relative to the STRAWBERRY SEASON—"The produce of Strawberries, from what a few years ago was common waste land in the neighbourhood

of Sarisbury Green, has this year been as great and the cultivation as successful as in previous years. At Shirley Mr. G. Payne has some splendid Strawberry beds covering several acres of what, only a short time back, was little better than rough waste. By enterprise and industry he has been able to pick from these beds some hundreds of gallons of Strawberries daily during several weeks past. These have found a ready market in Southampton and London. It is said that something like twenty tons per day have been sent to London from Botley in the height of the season."

— THE attention of CHERRY GROWERS is invited by the Secretaries of the South Chiltern Cottagers' Horticultural Society—an association of a few villagers on the Chilterns—to the following notice. His Highness the Maharajah of Benares, being interested in the cultivation of the Cherry, has offered through one of his English friends resident in that part of the Chilterns some prizes for the encouragement of Cherry culture. These prizes are mainly limited to the locality; but one prize of £1 is offered for the two best dishes of Cherries of any description, thirty of each sort, without any restriction as to place of residence. The Committee would be very glad to receive for exhibition some good samples of this fruit, both because it would tend to improve the culture of Cherries in the district, and because it would be a gratification to them to report to the Maharajah that his offer had been responded to by persons outside the district. Growers who would not generally send to a local show are invited to do so, in appreciation of the kindly feeling towards Englishmen which this Indian Prince has ever shown in little as well as in great matters. The Show is at Woodcote House near Reading, on Wednesday July 21st. The Secretaries, Rev. C. J. Abbey, Checkendon Rectory, near Reading, and Rev. H. G. Nird, Woodcote House near Reading, will gladly take charge of any parcel directed to either of them upon information by post. Entrance fee 1s. 6d., which may enable a second prize to be given.

— WE have received from Mr. Fox, Banbury, flowers of the NEW DWARF DOUBLE-FLOWERING TROPÆOLUM HERMINE GRASSHOFF; the original plants having been received from Mons. Grashoff of Quedlingburg. The flowers are very double, with broader petals than the old double scarlet Tropæolum, and we think they are even brighter in colour. The plants of Hermine Grashoff are described as very dwarf, only reaching 12 to 15 inches in height, and bloom freely the whole of the winter months. This variety therefore promises to be of considerable value for decorative purposes, and affording brilliant flowers for cutting for vase decoration.

— A WARRINGTON correspondent writing to us on the WEATHER and ROSES states that he has not yet cut a good bloom, all being more or less blistered by bright sunshine suddenly following frequent showers. We have seen many blooms at the shows that have been similarly injured, but those that have been protected are unusually brilliant in colour.

— We are informed that the POTATO DISEASE is very bad in the low-lying parts of Essex, where heavy rains have prevailed and saturated the soil. The crops in the cottagers' gardens are the most affected, especially the Early Shaws. In small confined gardens the soil is generally richer than in open fields, and the growth is more succulent and crowded, hence the liability to injury of Potatoes grown under such conditions. We may add that we have already seen Scotch Champion, Magnum Bonum, and Grampian, so called "disease-proof" varieties, affected with the murrain.

— WE have received from Mr. Stephen Castle, manager, The Vineyards, West Lynn, Norfolk, some fine specimens of TOMATOES. A bunch of Suttons' Conqueror, a smooth medium-sized fruit of

excellent quality, with twenty fruits. This variety is very productive, Mr. Castle having cut bunches 6 lbs. in weight. He has also sent specimens of his seedling, one of which weighs 14½ ozs. It is rather corrugated, and its chief merit consists in its firm flesh and excellent quality. Those—and the number is increasing—who enjoy Tomatoes in a raw state will find this one of the best. The smaller fruits are smooth and of suitable size for placing on the table.

SCALDED GRAPES—RED SPIDER.

ONE of the most frequent causes of "scalding" when late Grapes and Muscats are undergoing the critical process of stoning, is the result of allowing the temperature to fall too low at night, and then neglecting to admit air early in the morning to disperse the moisture condensed on the fruit. The best preventive of scalding is a night temperature of 65° to 70°, and abundance of air by day, under which treatment the occurrence is rare even with such kinds as Lady Downe's, one of the most liable to it; indeed no economy is so false as not continuing the fires as an auxiliary to solar heat, so as to ripen the Grapes whilst there is plenty of light, and external circumstances admit of free ventilation. Red spider is unusually abundant this season. The best remedy is to paint the hot-water pipes with sulphur, and the best preventive plenty of nutriment both at the roots and in the atmosphere, affording copious waterings with liquid manure at the roots, and a moist atmosphere by frequently damping available surfaces, especially at closing time, with guano water, or sprinkling with guano in the house, and syringing over it. The ammonia given off by this is beneficial to the foliage and inimical to insect life.—AN OLD GROWER.

THE REV. W. F. RADCLYFFE.

I AM sure that there are no readers of the Journal (especially those who love the Rose) but will feel that both it and they have sustained an immense loss by the death of my dear old friend Mr. Radclyffe, and as far as I myself am concerned I cannot say how great a blank it has made. For upwards of twenty years we have enjoyed one another's friendship, we have had the same sympathies and tastes; and although we were separated far from one another, yet it made perhaps our meeting, which I always tried to arrange when practicable, the more enjoyable.

I have so often described his residence, so often written of himself, that I feel I have little now to add to those words I have already written; but yet I cannot allow him to pass away without adding one more tribute to his worth.

As a rosarian few equalled him in ardour and enthusiasm; none excelled him in his love for the Rose. He loved it, not as an exhibitor loves it, but for itself alone. He did in former years exhibit both provincially and in London, and was successful; but for the last fourteen or fifteen years his Roses were grown for his own special enjoyment, and that of his friends and neighbours, whom he was glad to admit to see his garden at all times. Fruit, too, he delighted to grow, and his Peach trees at Rushton were a marvel of beauty and culture. And yet he cared little for fruit itself. To send a dish of Strawberries to a sick neighbour, or baskets of his luscious Peaches to his friends, was a greater enjoyment to him than eating them himself. He liked to have the best of everything he grew, always saying that it took as little trouble to grow good things as indifferent ones; and hence—whether it was Potatoes, Peaches, or Roses—he would have nothing that he considered bad or indifferent. Of course his taste varied, as all tastes do; people were not always able to agree with them, but as a rule his judgment was sound.

I can add but little to my estimate, so often given of his character. He was, in a word, that highest type of man—a Christian gentleman; a gentleman by birth and in feeling, incapable of a mean or ungenerous action, open-hearted, and free-handed in every case of distress, and obeying strictly the mandate not to let his left hand know what his right did. Living a secluded life, and disliking society, he was no doubt in some respects peculiar, but in all respects to be honoured and loved. The friendship began with him at Rushton is now broken for ever here, to be renewed I hope in that better land whose flowers are undying and whose joys are unbroken. He has left but few like him, and all who knew him may well cherish his memory. He was seventy-five years of age.—D., Deal.

STRAWBERRY PAULINE.

THE truss of fruit represented in the annexed figure is shown as produced by a plant sent to us by Mr. George Paul of Cheshunt.

The other portions of the plant were removed so as to better show the strength of the footstalk of the variety, which, as will be seen, is remarkable; but the merit of this Strawberry consists in combining earliness and high quality with size and firmness. Mr. Paul informs us that it ripens at the same time as Black Prince and Vicomtesse Hericart de Thury, and is as prolific as the

last-named variety, and when the first dish of Pauline was gathered Laxton's Pioneer growing in the same row was only just colouring. Pauline was raised by Dr. Morère, and has been grown at Cheshunt for five or six years, and it is a little surprising that a variety so distinct has not become more widely known. The flower is also distinct by its bold shape, the fruit almost forming

Fig. 14.—STRAWBERRY PAULINE.

before the flower expands. Possibly in all soils this variety may not succeed so well as at Cheshunt, but judging from the fine example submitted to us we think it well worthy of trial in various districts. The following is the description of the fruit:—Fruit large, oblong, and corrugated; deep red, and with a large

number of small seeds strewed over the surface, and with a long glossy neck like the Old Pine. Flesh very solid, stained with red for some distance under the surface; briskly flavoured, sweet, and with a very high flavour of the Old Pine. The flavour is very rich, and a fruit left over from Saturday till Monday,

instead of decaying became shrivelled, firm, and delicious. A very excellent Strawberry. The footstalk unusually thick as well as the scape, and the plant very vigorous and a great bearer.

ROYAL HORTICULTURAL SOCIETY.

JULY 13TH.

THE Society's Meeting on Tuesday last was unusually large and interesting for this time of year, the Council-room being completely filled with plants, flowers, and fruit from a number of exhibitors. Tuberous Begonias were strongly represented; the other most noteworthy exhibits being the superb collection of Japanese Iris blooms from Messrs. J. Veitch & Sons, Chelsea, their Orchids and new plants, and the collection of Lettuces in the vestibule from Messrs. J. Carter and Co., High Holborn.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Fruit and vegetables were not quite so abundant as the plants and flowers, but several exhibitors staged collections deserving of notice. Mr. Lyon, gardener to Sir E. H. Scott, Sundridge Park, Bromley, Kent, exhibited dishes of fine Elruge Nectarines and Grosse Mignonne Peaches; the latter were very large, and a vote of thanks was accorded for them. Mr. Whitaker, gardener to Lord Crewe, sent dishes of Lord Napier Nectarines, for which a cultural commendation was awarded. The fruits were of good size and well ripened. From the Society's garden fruits of a hybrid Strawberry were sent, the hybrid being the result of a cross between *Fragaria lucida* and *F. carolina*. The fruits were rather small, but of a rich and peculiar flavour. It was characterised by the Committee as an interesting cross of good habit, abundant bearer, and novel flavour, but not of sufficient size or importance to merit a first-class certificate. Mr. Ward, Longford Castle Gardens, Salisbury, sent a seedling Melon, which was considered as a good ordinary Melon, but not superior to others in cultivation. Messrs. Bunyard & Co., Maidstone, sent small branches of Currants most profusely laden with fruits. The varieties were Ruby Castle, Early Red, and Baldwin's Black. A vote of thanks was accorded. Mr. Pearson, 5, Water Lane, Brixton, sent fruits of a seedling Strawberry, very large but not in good condition. Mr. Hinds, Canford Manor, Wimborne, sent a collection of vegetables, comprising very clean well-grown samples of Peas, Beans, Carrots, and Potatoes. The Committee signified their appreciation of the quality by awarding a cultural commendation. A bronze medal was awarded to Messrs. J. Carter and Co. for their great collection of Lettuces, which comprised over two hundred varieties, representing all the principal forms in cultivation.

FLORAL COMMITTEE.—Dr. Denny in the chair. This Committee had a large number of new and beautiful plants submitted to their attention, and that the exhibits possessed considerable merit may be judged from the number of first-class certificates awarded. Messrs. J. Veitch & Sons, Chelsea, had a fine group of Tuberous Begonias, Orchids, and new plants. Some of the most noticeable Begonias were the dwarf forms. Mrs. Arthur Potts with rich crimson flowers; B. Davis with neat bright scarlet flowers. Of the larger varieties Brilliant with enormous scarlet flowers; Le Géant, also with large blooms; Emperor, Monarch, the pretty white form Reine Blanche: several named seedlings, *Rosea grandiflora*, and Countess of Kingston described below. An exceptionally beautiful collection of Japanese Irises was also exhibited which were very greatly admired. The varieties were not of English origin, having all been introduced from Japan by Messrs. Veitch; the diversity and beauty of the colouring were most attractive. Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorset, sent a group of Orchids, among which was a grand specimen of *Grammatophyllum Ellisii*, with a raceme considerably over 2 feet in length and bearing nearly fifty of its peculiar brownish flowers with small yellowish spots; *Nanodes Medusæ* had several of its strange dull reddish-coloured flowers with large fringed labellums; the delicate and elegant *Ionopsis paniculata* was flowering freely; *Utricularia Endresii* also being represented by an attractive specimen. Cultural commendations were awarded for these plants. Mr. H. Coppin, Rose Nurseries, Shirley, Croydon, obtained a vote of thanks for a group of Tuberous Begonias, containing several well grown and finely flowered specimens, also four boxes of cut Roses fresh and good. Mr. H. Cannell, Swanley, Kent, had a large stand of Verbenas, a number of varieties being represented, many of considerable beauty. A medal was awarded. Captain Patton, Langford Place, Abbey Road, N. (gardener, Mr. Borthwick), sent a *Coleus* named Allan Chandler, with leaves of great size, crimson marked with maroon, and edged with yellow and green, very bright in colour, a good variety, but with some others also exhibited on this occasion it was not considered sufficiently distinct from the numerous forms in cultivation to merit a certificate. Messrs. Heath & Son, Exotic Nursery, Cheltenham, were accorded a vote of thanks for a plant of *Epidendrum elatum* bearing a fine panicle of flowers, the fragrance of which strongly resembles that of ripe Pears. Mr. C. J. Salter, gardener to G. Southgate, Esq., Selborne, Streatham, was accorded a vote of thanks for a basket of plants of *Phalænopsis grandiflora*, bearing a large number of fine flowers; one inflorescence had sixteen flowers, and others from eight to ten. Mr. Salter also sent a basket of *Oncidium*s of several species flowering freely. From the Society's garden were sent several of Lemoine's *Pelargonium*s, also a group of seedling Begonias of especial merit, the habit being good, the flowers

large and richly coloured. As arranged with pots of Mignonette the effect was very pleasing. Plants of *Gomphrena globosa nana* were also shown; as its name signifies, it differs from the ordinary form in the dwarf and compact habit. A vote of thanks was accorded to G. F. Wilson, F.R.S., Weybridge, for flowers of *Liliums*, including *L. pardalinum*, *L. californicum*, and a seedling. Messrs. Cutbush and Son, Highgate, had a collection of Ivies in the vestibule comprising about fifty varieties, several of considerable beauty.

First-class certificates were awarded for the following plants:—To Mr. H. Coppin for a seedling *Tuberous Begonia Mrs. H. Coppin*, a very distinct variety, with very large yellow flowers of good form; the leaves were somewhat of the Pearcei type in colouring, but very large, some being about 10 or 12 inches in length. The habit was compact and good, and the variety appears one of great excellence. To Messrs. Veitch & Son for *Tuberous Begonia Rosea grandiflora*, a beautiful variety, with flowers of enormous size, about 4 to 5 inches in diameter, of neat form, and pale pink in colour, very distinct and attractive; *Cypripedium Morganianum*, a hybrid between *C. Stonei* and *C. Veitchi*, with narrow petals about 4 inches in length, spotted with dark purple, the sepals were of a light colour faintly striped with purple; *Tuberous Begonia Countess of Kingston*, of dwarf habit, with large well-formed flowers of a rich crimson tint. In the colour and symmetry of the flowers this fine variety could scarcely be surpassed. The following varieties of *Iris Kampferi* were also deservedly certificated:—*Carnation*, very large flowers, peculiarly streaked with purple on a lighter ground; *Striata superba*, very neat symmetrical flowers with a pale lilac ground, marked with fine purple veins, and having purplish blue stigmas; *Imperial Wonder*, large circular flowers, spotted and streaked with white and two shades of purple; *Kosoburo San*, falls and standards broad and rounded, streaked and veined with purple on a light colour, very distinct and beautiful; *Delicata*, flowers of moderate size, semi-double, white in centre, lilac blue towards the margin, very chaste. To Mr. C. Turner, Slough, for *Rose Mrs. Harry Turner*, a Hybrid Perpetual with neat compact blooms of good substance and a surprising richness of colour. The shade was a deep rich crimson with a velvety sheen; very effective. *Picotee Clara Penson*, a light-edged variety of symmetrical form, full, pure white with a clear narrow margin of purple. To Mr. W. Bull for *Lilium canadense splendens*, a variety of this well-known species with a single neat flower of moderate size, the perianth divisions acute, reddish in colour, thickly spotted with black; very pretty and distinct. To Messrs. Cutbush and Osborn for *Hedera maderiensis*, an Ivy with small leaves variegated with white. To Mr. R. Lewis, St. Austins, South Norwood, for *Coleus Sowteri*, a distinct and attractive variety with neatly formed leaves, rich crimson in the centre, and margined with an even band of yellow. To Mr. J. King for *Begonia Mary Steele*, a tuberous variety of the Pearcei type, very floriferous, of good compact habit and bearing circular flowers of a fine yellow tint. *Tuberous Begonia A. Hemsley* from the Society's gardens at Chiswick was also honoured with a certificate. It was exhibited as a "decorative variety," a term which was apparently intended to indicate the dwarf compact habit and floriferousness of the variety. The flowers were very freely produced, and of a fine pink hue. Messrs. W. Paul & Son, Waltham Cross, also obtained a first-class certificate for *Rose Pride of Waltham*, which is described in the report of the Alexandra Palace Rose Show.

SCIENTIFIC COMMITTEE.—Sir Joseph Hooker in the chair. Mr. W. G. Smith exhibited water-colour drawings of certain furnaces for smelting iron in Scotland, the volumes of smoke of which were destroying Conifers in the neighbourhood; a drawing of *Lilium giganteum* from Mr. Noble's nursery, Bagshot; and a fasciated peduncle of the Ox-eye Daisy, with three flower heads combined. Dr. Gilbert exhibited specimens of Bacteria and other organisms which are supposed to produce nitrification. Certain solutions containing nitrous acid were found to pass into nitric acid whenever the organisms were present, not otherwise. Dr. Masters reports that they consist of numerous micrococci, algæ growth and Bacteria. Dr. Masters exhibited a specimen of the rare *Simethis bicolor* from Bournemouth. Rev. A. Rawson for a fasciated branch of Ash from Bromley Common. Mr. MacLachlan exhibited a specimen of sugarcane from Queensland attacked by the larva (also exhibited) of some unknown moth, probably of the Pyrelidæ. It resembles the injury done to the canes in the West Indies, Mauritius, &c. The larva appears to bore into the stem just above the leaf insertion, the egg having been laid in the axil, hence the desirability of stripping off the lower leaves. He also exhibited a Tulip capsule with a supernumerary carpel adherent, but open with exposed seed. Mr. James (Norwood) exhibited a series of blossoms of *Oncidium Gardnerii*, showing no specific difference between that and *O. curtum*. The Rev. G. Henslow (Secretary) exhibited several Cabbage leaves with abnormal foliar appendages and pitchers from a field near Hitchin; also *Iberis amara*, and remarkably tall specimens of *Rhinanthus Crista galli* from a corn field at the same place.

PYRETHRUMS.—These are certain to become as popular, or perhaps more so, than Chrysanthemums. In two long broad borders 400 feet or more in length they are planted from 6 to 9 feet apart, large plants with dozens of blooms each, and the effect is very fine. And then what handfuls or basketfuls of cut flowers can be gathered from them! No doubt that in ten years'

time they will be general favourites. Their only failing is the lack of scent.—R. P. BROTHERSTON.

PEACH BLISTER.

MR. TAYLOR'S notes in the last issue of your last volume added one more proof to the thousand and one already in existence of how all-important the protection of glass is to ripen the annual growth of Peach trees. If it be correct that well-ripened wood ensures the safety of the foliage from north-east and south-east winds—and I by no means grant that it does—how are we to get the wood ripened upon open walls in a wet summer? If anyone will tell us that, or of a sure remedy for the blister, we shall be most grateful.

Last year I called attention to the fact of some varieties of Peaches being much more liable to suffer from blister than others, giving examples of trees in my own hands growing side by side under precisely similar conditions, some of which were quite crippled and stunted by blister, while others enjoyed a comparative immunity from it, the apparent cause being tissue sufficiently stout in the young foliage to withstand the attacks of cold blasts—growing quickly, and coming to full development without a blemish. Varieties possessing this valuable property are what we require for open walls, for, however delicious and fine may be the fruit of varieties having tender foliage, they are not to be depended upon for an annual supply of it without the protection of glass. Plant them by open walls, and for two or three years all may go well; they may have become flourishing trees laden with heavy crops of fruit, but a change will inevitably come over the scene. Cold ungenial springs will occur, blister will affect the foliage, much of the blossom will prove abortive, and the trees will present a crippled, stunted, half bare appearance till the full strong growth of kindly midsummer hides the ravages of fickle spring. This summer growth fills the wall space, but it will not be well ripened unless the autumn prove exceptionally warm and fine. Two precious months have been lost by the crippling of the spring growth. If this meant only a passing disfigurement of the trees it would be immaterial, but it too often involves the loss of the fruit crop in the following year.—EDWARD LUCKHURST.

ABUTILON INSIGNE.

A CORRESPONDENT informs us that he has received what he believes to be this plant under another name, and he assumes that others are in the same position as he is. The accompanying figure will enable anyone to identify the plant, which is distinct in the formation of its flowers from all other Abutilons, and is very handsome, with dark green persistent foliage. *A. insigne* (Handsome-flowered Abutilon) has branches clothed with dense down. The leaves are large, on long petioles, alternate, cordate, somewhat three-lobed, and coarsely serrated, palmate-seven-nerved, with reticulated veins. The flowers are about 2 inches in diameter, and grow in axillary racemes of three to seven flowers. The calyx is campanulate, with triangular acute lobes; the corolla consists of five obovate cuneate petals, crisped, and plicate with erose

margins; they are of a lively rose colour, with deep-coloured veins. The ground colour of the large petals is white, but that is almost entirely obliterated by the rich carmine veining or reticulation both without and within, but brightest on the upper side.

THE WEST OF ENGLAND ROSE SHOW.

HEREFORD, JULY 7TH.

THIS, the fourteenth annual Exhibition of the Society, was not quite equal to some former shows, notably that of last year; but, as was remarked of Mr. Baker's Roses at the Palace, so at Hereford, it is impossible to speak too highly of the wonderful colour, lifelike freshness, and smoothness of his blooms. This is a fact generally apparent in this great exhibitor's collection; his chief weakness lay in the great size of the majority of his blooms not being carried out through his collection—a specimen or two in a weak corner would crop up. Mr. Jowitt's blooms, on the contrary, were large, well sustained throughout, and quite as well set up as Mr. Baker's, but certainly lacking in colour and smoothness, and showing manifest signs of an unequal struggle with the elements, especially when called upon to bear the burden and heat of the day. Many of Mr. Jowitt's delicate blooms evidently had had the shelter of glass, or otherwise they could not have been staged in this high state of perfection.

Mr. Baker carried off the special prize, given by Mr. B. Cant (£5), for thirty-six varieties, with a superb collection. The second prize was taken by Mr. Jowitt with admirable blooms. In eighteen varieties, three trusses, Mr. Baker had to change places with Mr. Jowitt in order of merit, the latter carrying off first prize; but the Judges must have had some trouble to decide, so superb in colour, size, and shape were both collections. As in the previous class, Mr. Baker's Roses were superior in colour and freshness, and specimens of *J. S. Mill* and *Duchesse de Vallombrosa* were each faultless; while in Mr. Jowitt's winning collection the triple groups of *Marie Baumann* (a marvel of *embonpoint* symmetry)

and good old *John Hopper* (so fresh and bright) could not be surpassed.

In twenty-four varieties Mr. Jowitt, Mr. Baker, and Mr. Arkwright were awarded the prizes in the order named. Grand blooms were staged in these collections especially in Mr. Jowitt's. In twelve varieties in a numerous class Mr. Jowitt was again first with a splendid large and level lot, Mr. R. Crossling second, and Mr. Baker third. Mr. Jowitt showed *H.P. Henri Ledechaux*, splendid; and Mr. R. Crossling *H.P. Pierre Notting*, grand in colour and substance. Messrs. Cranston's special prize for twelve blooms of any Rose was won by Mr. Jowitt with remarkable blooms of *H.P. François Michelin*; while a similar prize, offered for *Noisette Maréchal Niel*, failed to bring a single competitor. Three blooms of any English Rose not yet in commerce was won by Mr. Talbot, gardener to Mr. Arkwright, who staged two varieties, neither of which appeared sufficiently distinct to require any especial notice. In the class restricted to amateurs living in Herefordshire, twenty-four vars., single blooms, the first prize (the special gift of Mr. Arkwright), was gained by Miss Bulmer with fine well-coloured blooms; *J. Pulley*, Esq., M.P., second; Mr. A. G. Grant third, and Mr. J. G. Woodhouse fourth. In this division the competition was numerous and close in every class.

In the open class for twelve new Roses sent out in 1877, 1878, 1879, or 1880 Messrs. Curtis & Sanford gained the first prize. The exhibits in these classes were not up to the usual mark as regards quality and condition. The greatest acquisitions appeared to be *H.P. The Dean* of Windsor and *Barthelemy Joubert* in Messrs. Curtis & Co.'s collection,

Fig. 15.—ABUTILON INSIGNE.

and Madame Gabriel Luizet (far the most promising variety) in Mr. Cranston's third-prize collection; the second prize falling to Messrs. Davison. The same remarks hold good in respect to the Tea and Noisette classes, in which Messrs. Davison & Co. took first prize; but where Messrs. Cant, Mitchell, and Prince are unable to exhibit, or not at all in their usual form, a temporary eclipse of this loveliest type of Rose must be expected.

Coming down last, but certainly not least in point of importance, to the nurserymen's division, Messrs. Cranston & Co., as a foregone conclusion from their former triumphs this season, carried off first honours with grand examples of the leading exhibition varieties. Messrs. Curtis & Sanford took second prize with a smaller but fresh and good collection. For thirty-six varieties, trebles, Messrs. Cranston were again first, and Messrs. Davison & Co. second. For twenty-four varieties, single trusses, Messrs. Cranston & Co. and Messrs. Davison and Co. were first and second in the order named. In eighteen varieties, trebles, Messrs. Jefferies & Son, Cirencester, gained first prize with a remarkably clean and fresh collection. The second and third prizes in this class were not awarded. In Class 24, varieties, single blooms, Mr. Griffiths, Tillington Nurseries, and Mr. Wm. Lee, Lyonsall, gained first and second prizes with admirable collections after very close competition.

It only remains to state that the floral decorations for which the Exhibition has attained considerable reputation were even on a larger scale than usual, and must have considerably taxed all the experience and talent which the Hon. and Rev. J. T. Boscawen (who acted as Judge in this division), is so well known to possess, in discriminating between their rival merits. Through the courtesy and efficiency of the hall manager, Mr. Beddoe, all arrangements seemed to give general satisfaction. There will be a new Honorary Secretary next year to the West of England Rose Show, but still an occasional reporter to our "Rose Journal" in the—HEREFORDSHIRE INCUMBENT.

KITCHEN GARDEN.

Early Cabbage.—A supply of Cabbage early in spring is of great importance. If the plants are too early there is danger of their running to seed in spring, hence the necessity of sowing so as to obviate this. From the 10th to the 16th of this month is quite safe for localities north of the Humber, but southward from the 16th to the 24th will be a suitable time for sowing. The seed should be sown rather thinly in an open situation, the object being to keep the plants sturdy and short in the stem from the commencement. Ellam's Early Dwarf is one of the best varieties, coming in very quickly; Hill's Dwarf Incomparable, Wheeler's Imperial, and Wheeler's Coconut are admirable early varieties, also Nonpareil Improved, Cattell's Reliance, and Enfield Market.

Cauliflowers.—Plants intended for yielding heads in autumn should be planted without delay, choosing an open situation and well-manured ground. Supply the plants freely with water, mulching the ground between the rows after the plants become established, and frequently water between the rows in dry weather, not only to increase the vigour of the plants but to prevent "buttoning."

Broccoli.—Plants of Veitch's Self-protecting Autumn and Snow's Winter Broccoli should be planted out at once, affording them if possible sheltered yet sunny situations. Heads may be obtained when those in exposed situations are damaged or destroyed. The present time is most suitable for planting out the main crops of spring and late Broccoli, which in most gardens make too robust and succulent growth, thus becoming more liable to be injured by frost than those grown in poorer soil. A loose soil also favours the tendency to excessive vigour; therefore in planting merely loosen the surface for the purpose of removing weeds, and before planting give a dressing of salt to ground where the crops suffer from ambury or club, half peck per rod being a sufficient dressing, or nitrate of soda 1 lb. per rod.

As ground becomes cleared of Potatoes, Peas, &c., plant Savoys, Borecoles, and Kales for a good supply of winter greens. Sow a good breadth of Turnips for late summer and autumn use, and continue successional sowings of Radishes, Round Spinach, and Lettuce. The main crop of Endive should now be sown; Round-leaved Batavian and Green Curled are suitable varieties, Picus being a very desirable finely curled or cut variety, with a large quantity of edible leaves which are readily blanched. Parsley which has been transplanted

endures the winter much better than that allowed to remain where it was sown, therefore transplant some where protection can be afforded in severe weather.

HARDY FRUIT GARDEN.

Continue to carry out former directions as regards the stopping or removal of superfluous or foreright shoots of all kinds of fruit trees, nailing or tying-in when trained to walls, so as to afford the advantage of increased sunshine and air to ripen the wood and buds. Figs on walls should have similar attention, the points of all shoots being pinched out except the leaders, and where the shoots are crowded they should be well thinned out. Vines trained to walls should have the growths closely nailed in, the laterals kept well pinched and superfluous growths removed, so as to afford the wood and fruit the fullest advantage of sun and air. Many outdoor fruits will now require to be protected by nets from the ravages of birds.

Strawberries.—Ground intended for new plantations should now be prepared by heavy manuring and deep trenching, or at least by being deeply dug. Preparation will also require to be made of plants for planting; and the best plan is to layer runners in small pots, selecting the runners from fruitful plants only, and by attention to watering in dry weather they will soon fill the pots with roots, when they should be planted out and attended to with water until established. If kept free from weeds and runners they will afford a crop of fruit next season, as full as plants allowed to root in the soil naturally will do in the second year; indeed the finest fruit will be had the season following planting, amply repaying the little extra trouble of layering in pots. In light soils the Strawberry should be treated as a biennial or at most as a triennial crop, whilst in heavy soil the plants have longer staying power, and will continue in bearing. The plants may be placed 15 inches asunder in rows 30 to 36 inches apart, which will be sufficient space the first season and ensure a fuller crop. But as soon as the fruit is gathered every alternate plant should be removed, which will leave them 30 inches asunder every way, more and finer fruit being had than by overcrowding. Pioneer, Vicomtesse Hericart de Thury, President, Sir Joseph Paxton, Lucas, Loxford Hall Seedling, Eureka, Dr. Hogg, and Unser Fritz are reliable varieties.

PLANT HOUSES.

Orchids.—Thunia Bensoniæ and T. albus come into flower about this time, and are valuable when many are on the wane. They should be in every collection, and are of easy culture, needing much the same treatment during growth as Calanthes. Supply the latter with weak liquid manure, also Limatodes rosea; and as they are subject to attacks of red spider, thrips, and scale, sponge the leaves with soapy water and afterwards with clean rain water. Cattleyas and Lælias in growth require plenty of moisture to enable them to make strong, plump, pseudo-bulbs. Many of the early-growing Orchids will have completed their growths for the season, and will require to be removed to a cooler house, where they can have more air and light, and a temperature of about 60° without sun heat. Dendrobium nobile, D. Cambridgeanum, with others of the genus, if retained in their growing quarters, will often make a second growth, which seldom becomes well matured; therefore place them in a house with less moisture and heat, ventilating freely. Keep the Odontoglossum house cool and moist, affording plenty of water to the roots of those growing freely. Odontoglossums and Masdevallias growing strongly and having filled their pots with roots should now have a shift. Sobralias being subject to red spider should be freely syringed and the leaves sponged. Frequent fumigation will be necessary to keep down aphides and thrips.

Greenhouse.—In hot weather hardwooded plants will require very considerable and careful attention in watering. Plants in vigorous growth and having abundance of roots may not show any indication of requiring water in the morning, but they should be examined before the usual time of watering in the afternoon, and be supplied as needed. Mischief is often done by permitting a plant to flag and then saturating the soil. In an hour or two the plant will freshen up and may appear all right, but in a week or two it will begin to flag at the points when exposed to the full sun, and this time it is not by want of water, for the soil is found wet enough, and if the plant is turned out many of the roots will be found dead. It is the heavy first watering after becoming dry that is the cause of this,

and which a more judicious application would have prevented. When a plant, therefore, is found dry in the middle of the day it should at once be shaded, the atmosphere around thoroughly moistened by copious applications of water, damping the outside of the pot repeatedly until it becomes thoroughly wet, slightly damping overhead to prevent evaporation; and when the plant is recovering, as it will towards evening, afford water thoroughly to the roots. This may be the means of saving many fine specimens. Another evil in watering at this season is the supply from cisterns being exhausted; spring water is employed not only several degrees lower in temperature but very hard. To prevent the injurious effects of well water to hardwooded plants it should be fully exposed to the air for several days before use.

Pelargoniums.—Early-flowered plants are very valuable, such as Bridal Bouquet and Duchess of Bedford, both being very chaste, pure white, prettily fringed with feathered rose spot in the upper petals. They should be placed outdoors in the full sun without delay to thoroughly ripen their wood previously to being cut down, affording water only to prevent flagging. The Regal varieties are particularly valuable for bouquets and decorative purposes. Some of the best are Princess of Wales; Maid of Kent, with rose spots on all the petals; Prince of Teck, Queen Victoria, Captain Raikes, and Beauty of Oxtou.

Liliums.—Plants of *L. auratum* coming on for later flowering should be top-dressed with decayed manure, and have careful attention in watering and securing to stakes, or they will be liable to be damaged by strong winds. Plants that have flowered should be placed outdoors and properly attended to with water, as the longer they retain the foliage the stronger the bulbs will be, on which so much depends for next season's flowering. *L. speciosum* vars. should have weak liquid manure occasionally, and must be kept free from aphides, which if allowed to increase completely spoils both flowers and foliage.

Heaths.—Early-flowering plants should be placed outside, and should have slight shade for a few hours in the hottest part of the day. Place the pots on a bed of ashes at least 6 inches thick, which should always be kept moist, as when the plants are on inverted pots they from drought become brown in leaf and have a starved appearance. Sometimes red spider attacks the plants, and in this case lay them on their sides and syringe thoroughly with clean water about twice a week.

TRADE CATALOGUE RECEIVED.

E. H. Krelage & Son, Keinen, Hartweg, Haarlem.—*Wholesale Catalogue of Bulbous and Tuberous-rooted Plants.*

Books (*A New Subscriber*).—We know of no treatise such as you appear to require. You will find an excellent mode of destroying the Gooseberry caterpillar on page 454, the issue of June 10th; and you may readily destroy aphides on Roses and Asters by syringing them with a solution of soft soap and tobacco water, 2 ozs. of the former and half a pint of the latter to a gallon of water. Gishurst compound has the same effect, as also have other insecticides that are advertised in the Journal. It is a great mistake to permit insects to increase in large numbers before adopting means of destroying them. Those who act on this principle never become successful cultivators. We will readily give you information on any question that perplexes you if you will state the case clearly and explicitly. (*W. N. Craig*).—Lowe's "Natural History of British Grasses," with seventy-two coloured plates, may possibly suit you. It is published by Groombridge & Son, price one guinea. Your other question shall have our attention.

Mimulus (*T. W.*).—The flowers having been sent in a letter instead of a small box were crushed into a shapeless mass, so that it is quite impossible to determine the merit of the variety. We may inform you, however, that hosc-in-hose varieties of *Mimulus* are quite common.

Peculiar Fern (*L. Blacky*).—The frond you sent is very distinct from *Adiantum gracillimum* in general appearance and form, but the pinnules are similar to those of that Fern. It is probably a form of *A. gracillimum*. The frond is bunched or fastigate, and if all are alike upon the plant you mention the effect must be very peculiar.

Seedling Viola (*J. M. Freeman*).—The flowers are very rich in colour, velvety purple, and as the plant is floriferous and a continuous bloomer the variety is likely to prove an acquisition for bedding and border decoration. We

advise you to exhibit flowering plants at some of the Scottish Pansy shows, as it is only by judging it in comparison with the best varieties its merits can be satisfactorily determined.

Thrips on Vines (*W. A. B.*).—Frequent light fumigations will not injure the Grapes that have just stoned, and if persisted in will probably eradicate the insects. We have often greatly checked their increase by dipping a sponge in a strong solution of softsoap and smearing the affected leaves, not syringing the Vines afterwards. An hour or two spent during the early morning in spouging the leaves would probably in your case be labour well invested. At what strength did you apply the paraffin to the Vine in the pot for extirpating ants?

Heating a Stove (*E. W., Maidenhead*).—You do not state the height of the stove, but only give its length and width. Unless the house is very lofty four rows of 4-inch pipes and sufficient boiler power will heat it efficiently. It is contrary to our practice, as we have often stated, to recommend boilers. All that are advertised in our columns are good when well managed, but all are not equally adapted to certain positions. Consult a practical gardener in your neighbourhood on this subject.

Onion Maggot (*W. Jones*).—As your Onions are "seriously affected" we know of nothing that will kill the maggot without also destroying the plants. If any of our readers can name a remedy we will gladly publish it.

Stopping Peach Trees (*Subscriber*).—Train in all the growths that are necessary for forming the trees, and do not stop them, but be sure they are not crowded. The foliage of one shoot should not overlap that of the other, therefore you must remove all the growths requisite for exposing fully to the light those remaining. The side growths for bearing next year must also be trained very thinly, and if they have formed triple buds the ends of the shoots may be pinched off in August at about 18 inches from the base. Strong growths do not always form triple buds near the base, but only towards the extremities, and therefore stopping must not be done indiscriminately. You do not say whether the trees are on open walls or under glass.

Pelargonium Beauty of Oxtou, "Sport" (*Florist*).—The truss is large and the flowers possess good substance. They are darker than the original, not possessing so much white in the centre nor round the margin of the petals. It is distinct, and like the original form will be useful for decorative purposes, but we do not think it likely to be of any great commercial value.

Propagating Tuberous Begonias (*C. L. C.*).—They strike readily from cuttings inserted in sand in a good bottom heat, choosing such shoots that have not a disposition to flower freely, indeed cuttings are best inserted before the flowering period. Cuttings struck now will not produce fine plants this year, but will form tubers that will produce good flowering plants next season.

Roses from Cuttings (*Idem*).—As the plants grow vigorously and yet do not bloom we conclude they have been pruned too closely. Roses on their own roots if they grow freely will, if rightly pruned, flower as freely as plants that are budded or grafted on other stocks. Thin-out the growths if crowded now, and only slightly shorten the others at the winter pruning, and your plants will flower next year.

Peach Trees Unhealthy (*H. E. C.*).—Had you sent us some wood as well as leaves we should have been in a better position to judge of the condition of your trees. The leaves indicate that the wood is ripening prematurely; if this is so the trees have not had sufficient water. They appear also to have been injured by the red spider, but there are no insects on the leaves sent. Have the trees been dressed with a strong insecticide, and so received injury? Examine the border, not on the surface merely, but 2 feet below, and possibly you will find it dry; if so, water it thoroughly, syringing the trees frequently, and if the crop is very heavy remove a portion of the fruit.

Beetles Eating Strawberries (*E. D.*).—The beetle sent is *Omascus melanarius*, a predaceous species, which preys upon other insects and small snails or slugs; it is therefore probable that these beetles have swept away the real cause of the mischief done to the Strawberries. Failing a supply of their natural food the beetles might possibly attack a juicy vegetable substance, but we cannot on research find any recorded instance of such an eccentricity.

Nicotine Soap (*R. A. J.*).—Mr. Abbey—in reply to the questions "Does nicotine soap injure plants if it gets to their roots? and does it stain the paint? Is it safe to syringe a conservatory with?"—states that he has used it extensively both for plants and fruit trees, and has not found any injurious effects result from syringing with a garden engine to either the foliage or roots. It does not stain the paint, at least not white paint, although it would probably leave a stain on other coloured paints, as it from being a soap dries white, similar to softsoap solutions, and it leaves a stain on glass. It is perfectly safe for syringing a conservatory, as the after syringings with clear water will remove its remains, and glass should have a thorough cleansing every now and again. The insecticide does not injure the plants, whilst it destroys every kind of insect infesting them. Clay's fertiliser is not inodorous, but the soil absorbs it so thoroughly that there is no unpleasant smell in ten minutes after the manure has been applied. Florvita is slightly fragrant. Both judiciously used are good for plants.

Eulalia japonica (*Idem*).—Messrs. Veitch give the following description of this plant, which we believe is quite correct:—"A very handsome perfectly hardy ornamental Grass. The stems, which attain a height of 5 feet and upwards, are somewhat slender; they are furnished with leaves upwards of a yard long and nearly an inch wide at the broadest, striped throughout with bands and lines of creamy white alternating with deep green. The flowers are pink, and are produced in panicles with spikelets from 8 to 10 inches long. The established plant sends up a tuft of graceful stems very elegant in growth, and at first sight appears to resemble the variegated *Arundo donax*, but it is quite distinct from and more hardy than that plant."

Vines Unsatisfactory (*C. L. C.*).—Many besides yourself have to complain of the bunches being small at the "bottom of the house," and the evil is generally caused by not shortening the canes sufficiently when the Vines are in a young state, cropping too heavily and restricting the lower laterals too severely. Many people, and amongst them some gardeners, suppose that by stopping those laterals that are weak they adopt the best means of strengthening them, whereas the very reverse is the case. Weakly laterals should be allowed to grow unchecked, or at least so far as can be done without causing the growth to be overcrowded, while those above them that are strong should be closely pinched. Further, the spurs and growths are mostly much too close together on the lower parts of Vines. A foot apart should be the minimum distance, and a space of 18 inches for each lateral is much better. You must not allow any bunches to remain on the weak laterals; thin them out if crowded, and permit the others to extend freely. Denuding the stems of all growth as is sometimes done, and too closely pinching the lower laterals, are the causes of many failures in Grape culture. If your Vines require a stimulant spread an ounce of guano on

each square yard of the border and water it well in, then cover the surface with rich manure; it may be placed 4 or 5 inches thick, and should not be raked off again but be left to decay and form part of the border. Surface roots should be encouraged, they are essential to short-jointed wood and fine fruit; but such roots are not promoted by covering Vine borders in winter and exposing the surface to the heat of summer, as if heat and drought would attract the roots upwards instead of, what is really the case, driving them downwards, a fact that many who attempt to grow Grapes do not appear to be acquainted with, or if they are they do not turn their knowledge to account so much as is desirable. Knowledge, it should be remembered, if not applied to a given object is just equal to ignorance. These remarks are called for by the condition of many Vines that come under our notice, and that we wish to see better, but as we have not seen your Vines our general observations necessarily do not apply to yourself.

Name of Fruits (W. Warren).—It is the Hantbois. (D. E.).—1, Jargonelle Pear, 2, Sorry we cannot name it in this condition; 3, Early Margaret Apple. Thanks for your flattering opinion of the Journal in its new form; we have had many similar expressions during the week. (A Subscriber).—The three Raspberries were completely smashed in coming through the post, and past recognition. The best sort of white Raspberry is the Yellow Antwerp.

Names of Plants (Mrs. Wolcombe).—The yellow flower is *Diplaeus glutinosus*, the other *Lychnis coronaria*. (John Bamber).—*Viburnum Opulus*. (Staines).—3, *Geranium pratense*. The others were too crushed to be recognisable. (W. H. Myers).—1, *Campanula carpatia alba plena*; 2, *Lilium Martagon*; 3, *Fuchsia microphylla*; 4, *Potentilla argentea*; 5, Too withered to determine with certainty, apparently an *Oenothera*. Of the specimens received last week the one with fleshy leaves is *Sedum pulchellum*, that with coloured foliage is *Agalmiyla staminea*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE ROYAL COUNTIES (HANTS AND BERKS) AGRICULTURAL SHOW.

(Continued from page 38.)

IN continuation of our report we will take the cattle; Short-horns first. For the best Shorthorned bull the first prize was awarded to Col. R. Loyd-Lindsay. This animal, three years and six months old, is well grown, with good points and of great weight for age, and of rare quality. The second prize was taken by Mr. John Walter of Wokingham for a huge animal, a mere mountain of flesh as regards size and weight; his age is, however, five years and three weeks, and when well bred, as this bull is, its enormous size gives it a noble appearance. The reserve number was given to Mr. Frederick Stratton, Merdon, Hursley, Winchester, for a capital animal of large size, his age being three years and three months, and bred by Mr. Joseph Stratton of Marlborough, and is of full pedigree. The formation or contour of this animal indicates his belonging to a generation of great milkers, but being rather light behind the shoulders has placed him third on the list, therefore in case he is used in a milking herd he has actually a value neither of the prize animals can claim for surety. For the best bull under three years old the chief prize was awarded to Col. Loyd-Lindsay for an animal only two years, seven months, and two weeks old. This is certainly as grand an animal, or more so, than any male Shorthorn exhibited, considering his age; and well adapted for use in a herd where exhibition animals are reared as a rule. For the best bull under two years old, five entries.—There was a very striking competition in this class taken altogether, and not one plain animal amongst them. Again Col. Loyd-Lindsay took the first prize with a splendid specimen of the breed only one year and seven months old, and we have no fault to find in this award. The second prize was given to Mr. C. Chapman, Frocester Court, Stonehouse, and to be placed second in such company is a great credit to the owner and breeder of this animal, which is only one year and ten months old, and is of full pedigree.

For the best bull calf above six months, and not exceeding twelve months of age; six entries.—First prize Mr. W. Nicholson, M.P., Basing Park, Alton, Hants. This was a beautiful animal, of rare outline and quality of flesh, and skin covered with soft

mossy hair, and being only seven months and two days old was also a great weight for age. The second prize—obtained by Mr. G. Garne, Chipping Norton—was for a calf ten months old. He was well bred, and being of great size for his age certainly looked older. This animal is of full pedigree, and is stated to be descended from the Butterfly tribe, and we well remember the celebrated bull (Master Butterfly) exhibited by Col. Townley at the Royal Meeting held at Canterbury in 1856, which was certainly the finest bull in all respects we have ever seen. This class, as a whole, was much to be commended. A calf in this class was exhibited by Her Majesty the Queen from the Show Farm, Windsor, but was not placed. We thought it was well bred, but not so well fed as some other exhibits. Class 32, for the best Shorthorned cow in calf or in milk; nine entries. The three prizes given in this class were well competed for, Mr. G. Garne taking the first prize with a remarkably fine animal in blooming condition, and is stated to be descended from Royal Butterfly, which tribe we have just stated stands high in our estimation. The second and third prizes were taken by Mr. Walter and Mr. Nicholson respectively with very fine animals; but we should not call them first-rate milkers. As the Society's conditions of the prizes does not oblige the Judges to award upon the milking capacity of the animals, the animals receiving these prizes were fully entitled to them. There were three commendations in this class irrespective of the reserved number; amongst the former was a very fine cow of full pedigree exhibited by Her Majesty the Queen, and bred upon the Show Farm at Windsor. Mr. F. Stratton showed a large well-bred cow, which was commended, and looked more like a good milker than any animal in this class; but we thought that it did not look so glossy in the coat as some of those beside her. This may probably arise from causes which are sure to tell against the appearance of exhibition stock, such as feeding only in the pastures without housing, for in our own practice we always box-feed exhibition stock; but it was altogether a fine animal, and, as stated in the catalogue, bred by Mr. B. St. John Ackers, of Brinknash Park, Gloucester, whose herd is of full pedigree and of long-standing celebrity. We could not help remarking that this cow in her form was exceedingly wide over the loin and hips, but rather narrow behind the shoulders, and that this illustrates practically the difference between deep milkers and animals of correct form, because, when outline is the chief guide in the selection and breeding of Shorthorns, the milking capacity is frequently only a secondary consideration.

For the best Shorthorned heifer under three years old; two entries.—First prize to Mr. W. Nicholson, the second prize to Her Majesty the Queen. Both animals exhibited in this class were remarkable specimens of the breed, and it was a credit to Mr. Nicholson to obtain first prize against such a good animal as that shown by Her Majesty. Classes 34 and 35, for which prizes were offered for heifers above one year old, and the best cow calf respectively. The entries were four animals in Class 33, and five entries for Class 35. Taking these two classes together we must say that they contained animals of great future promise, and the first prize in each having been awarded to Mr. Nicholson shows that he has laid a solid foundation of future excellence in his herd, and in both classes he again defeated Her Majesty, although the animals from the Show Farm were high bred, well fed, and of great weight for age. Longhorns.—Classes 36, 37, 38, and 39 were prizes for bull exceeding twelve months, for bull not exceeding two years old, for cow in calf or in milk, and for heifer not exceeding two years old. There was no competition in either class. All the prizes, however, were awarded to the President of the Society, Major-General Sir F. Fitz-Wigram, Bart., Leigh Park, Havant. The stock receiving the prizes in these classes were worthy of them in the estimation of the Judges; but the visitors at the Show, ourselves amongst others, did not admire

the breed much after seeing such fine animals of the other breeds. Herefords.—Although prizes were offered there were no entries. There are few herds of this breed of cattle to be found in the southern counties. There were prizes offered in six classes for bulls, cows, and heifers of this ancient and beautiful breed of cattle, which from time immemorial had been the exclusive breed of the south-western counties, but during the past twenty years the Shorthorns have displaced a great number of herds in their native counties. There were no more than three entries in either of the six classes, and the first prize was awarded in five classes to one exhibitor, Mr. W. R. Fryer of Lychett Minster, Poole, Dorset, which is a very remarkable success for his stock, because there were other herds well represented which possessed high quality and breeding. One prize, however, was taken for the bull of any age by Mr. John Walter, M.P., Wokingham. This was a large and well-bred animal for the breed, but they are now for the most part kept, like the South Down sheep, by farmers who have a fancy for them, and it is well that it should be so, for both are useful for crossing with other stock for improving their quality.

Sussex Cattle.—There was a good show of this breed, which has been improved very much within the past five years, and is now an excellent breed for producing animals when early maturity is required. They are also sought after for producing working animals. In some counties this plan of working oxen still prevails in spite of the advantages of steam culture. Classes 48 and 49, for bulls, two and six entries respectively. We noticed the first-prize bull, under three years old, belonging to Mr. J. S. Hodgson, Haslemere, Surrey, as being a grand animal of full pedigree. Class 50, six entries, for bulls not exceeding one year old. This was a capital show of bull calves, the first prize being awarded to Mr. J. A. Vickross of Hill, Sussex; the second prize being given to Messrs. Heasman of Worthing, who are celebrated as breeders of this kind of stock. Classes 51, 52, 53, and 54, for the best Sussex cow, heifer, and calf respectively. These classes were well contested, there being three entries of four animals and one of five. This speaks well for the Sussex stock, showing that they are increasing in numbers for certain purposes, but not as dairy stock. In three out of the four classes Messrs. Heasman take the first prize. We are particular in giving the names and addresses of the prizewinners, in order that the home farmer may know where to obtain the best of any of the stock exhibited. Channel Islands cattle.—The exhibits under this heading were the great and most attractive feature of the Show—at least as regards the amateur and butter-making dairy stock. Class 55, for the best Jersey or Alderney bull of any age, eight entries. First prize to Mrs. Malcolm, Lyndhurst, Hants. This animal was bred by Mr. C. Dixon, Southampton. The whole class was commended, Mr. Simpson taking the second prize. The class as a whole was the best of its kind we have ever seen, the colour of the animals being generally silver-grey. Classes 56 and 57 had five and eight entries respectively. First prizes were given to Lieut.-Col. Portal of Micheldever and Mr. George Simpson of Ryegate; Mr. John Cardus of West End, Southampton, taking a second prize in one case and a commendation in the other. The animals in these classes were very choice in breed, condition, and colour, and as a whole were better in outline and symmetry than we have previously noticed. Upon the general qualities of this breed it may be said they are becoming more fashionable and are kept in increasing numbers. For the best Jersey or Alderney cow in milk, fourteen entries. This was a beautiful show of first-class animals as dairy stock, as well as excellent specimens of the breed. First and second prizes were given to Mr. J. Knight of Farnham, Surrey, and Mr. George Simpson respectively, Mr. John Cardus taking the reserved number and a high commendation; in fact, these four cows were so near alike in outline and quality that without seeing them out of their pens it would be difficult to criticise the awards. Class 59, for the best Jersey or Alderney heifer under three years of age, fourteen entries. First prize was taken by Mr. G. Simpson, who was again to the fore with a rare heifer and excellent specimen of his choice collection and herd; Mr. G. A. Fuller of Dorking, Surrey, being second with a promising heifer of beautiful colour and quality. Her Majesty the Queen exhibited two very nice heifers from the Isle of Wight in this class, but they failed to attract the attention of the Judges so as to be awarded any commendation; it cannot, however, be considered any discredit in such a splendid array of heifers as this class brought together. For the best Jersey heifer under two years old, seventeen entries. This we thought the most interesting and beautiful display of young animals in the whole Show; the first prize being taken by Mr. J. Cardus of Town Hill, Southampton, places him in a high position, for in this class the stock of all the best breeders was exhibited; Mr. G. Simpson taking the second prize, Her Majesty again exhibiting a choice heifer both in form and quality.

A large number of commendations were given in this class. Class 61, for the best Jersey heifer not exceeding twelve months old, fifteen entries. The first prize was won by Mr. H. J. Cornish, Sherborne, Dorset; second Mr. G. Simpson; Mr. J. Cardus taking the reserved number and a high commendation. This is the class of promise for the future. Her Majesty the Queen, again contending in this class, was unsuccessful, for it is indeed a task and a study for any person however experienced and at whatever cost to insure success in such a splendid exhibition as the Jersey and Alderney stock afforded at the Royal Counties Show, 1880.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Ploughing the land and sowing the main crop of common Turnips will be continued at every interval when the horses are not required at work connected with the hay harvest in most of the districts of England, except in the northern counties, where sowing Turnips at the late period is not often attempted. As the roots will not grow up to so late a period as in the south and eastern part of the kingdom much land is being laid into permanent grass, especially on the strongest and flattest land, in nearly every part of the kingdom, and as the middle of August is the best time for sowing the seeds the land ought now to be nearly ready. Where many weeds prevail the land may now be ploughed and pressed, and worked down quite fine ready to receive the seed, and left ring-rolled in order that such small seeds as that of grass may not be buried too deeply in the earth, and instead of the old-fashioned brush harrow we have now the chain harrow lately improved by Howards of Bedford. The grass seeds, however, should be sown in separate lots, the heavy and light seeds, for these seeds will not mix properly, and in consequence cannot be sown so regularly either by hand or by Bennett's machine. For varieties of seed adapted to the various soils we must refer the home farmer to our article upon the subject in this Journal (page 105, vol. xxxviii.).

Stacking parkland and pasture hay must be continued at every opportunity, and if hay is taken to the stack rather hastily it is well to keep a long probing iron in the stack which may be withdrawn once or twice a day, and if the iron is too hot to bear holding by the hand it may then be pronounced to be in some danger of injury by overheating. As, however, the probing iron should have a barb or arrow head at the end a piece of hay may be pulled out from any part of the rick, showing the condition and colour of the hay, and enabling the home farmer to decide the point of overheating. If such should be the case the rick may be cut at the side and lay open for a day or two and straw filled in; this will generally prevent any excessive heat and damage, sometimes resulting in taking fire. We have sometimes adopted the plan of using a sack stuffed full and firm with straw, and in the act of building the rick the sack is lifted as the rick rises in making, and in this way a sort of chimney is made in the centre of the stack for the escape of any undue heat. Another plan we have adopted is turning the rick and making it again; but this will require watching as to the proper time of doing, because if we exceed five or six days from the time the rick was first erected the hay on the removal will not heat sufficiently the second time, or settle down close enough to prevent its turning mouldy. When, however, it is done at a suitable time we have on various occasions obtained some exceedingly choice and valuable Clover hay, especially adapted for lambs when feeding on roots.

Hand Labour.—Men will now be employed in hoeing and singling the root crops, and it is of much more consequence to save and leave the best and strongest plants than to thin them out with exact regularity as to distance apart. It is also of importance to leave the plants closer in the rows when late sown, for there is not the probability of making large bulbs like the early-sown. In fact, it is now more the practice than formerly to leave a greater number of plants to the rod, because it is considered that bulbs of moderate size are more nutritious than those of large dimensions. In thinning Carrots it will be remembered that we have advocated hoeing to keep the land clean between the lines, and that we object to thinning at the early stage or growth of the plants, as they are so liable to be eaten by the grubs; we have, therefore, left them until the roots become about the size of the finger, and then pull by hand the surplus roots, and carry them away for cattle-feeding. A tenant of ours has this year sown mixed seed, White Belgian and the Early Horn Red Carrot, so that in hand-thinning the Red Horn Carrots may be pulled and bunched for the vegetable markets instead of being given to the cattle, and this is a very suggestive practice. These Carrots being short in the root pull readily, and being bigger on the crown are easily seen at the time of pulling; they also open and leave the ground loose, enabling the large White Belgian Carrots left for the main crop to swell readily and become a weighty crop.

We must ask the home farmer now to consider the question of buying sheep stock, as the early fairs for the sale of the Hampshire Down breed will be now taking place, the first from this time being Overton, Alresford, Hants, and Britford in Wiltshire, at which fairs as well as various others which occur about this time, nearly all the best flocks are sold, especially of ewes intended for producing early lambs for the Easter markets. On many farms, particularly in the hill districts, water for the cattle and all purposes has been very scarce. It is often found, even where there are ponds for preserving

water in summer time, that enough cannot be obtained; we therefore recommend that the farm roads and parish roads are near the water tables and ditches should be kept scoured, and made to lead into the ordinary ponds; a thundershower will then often fill a pond, whereas if the water is not led into the pond it will go in other directions and be lost. Where the pastures have been fed we find in various instances that bunches and tufts of rushes appear, but now is the time to cut them close with the Gorse scythe, or what is better, to cut them up with the turf-cutting implement and burn into ashes, because we have found even where the land has been drained these tufts of rushes will live on after the subsoil water has been removed. The spring Beans are nearly everywhere covered on the tops of the stem with the black aphides; immediately this is seen they should be cut up and used as green fodder for cattle, especially pigs and young cattle, and the land ploughed and fallowed for wheat, except in those instances where Rape or Turnip seed were sown in the beans, in which case they may be dragged every few days whilst young, which will set them growing fast.

THE CROPS IN THE MIDLANDS.

A RUN northwards from London by the Midland railway enables the traveller to take a passing glance at the crops, and as it is fair to suppose that those by the line side are a type of others beyond them in the same district an idea can be formed of their general character. The condition of the various crops, meadow, grain, and roots at the present time is important for everybody, and fortunately all of them have a far better appearance than they had at the corresponding period last year.

For the first few miles we pass through a beautiful undulated and well-wooded "hay country," nearly all the land being meadow. Much of the grass is cut, some being secured. Generally speaking the herbage is short, and it is easy to see by the fields that are "down" that the crops are not heavy; indeed some of them are very light, indicating that the land does not receive such generous treatment as is desirable. There is no doubt whatever that many meadows would be vastly improved by liberal dressings of those fertilisers that are known to have such a potent effect, together with the sowing at the proper time of such renovating mixtures of those grasses and fodder plants that are best adapted to the nature of the soil.

For the next half hour or less the route is through a district where arable land prevails, and it must be said where Charlock reigns supreme. Many fields are like sheets of gold, and it is no exaggeration to say that two-thirds of the cost of such labour and manure as are applied to the land are really devoted to the culture of this exhausting weed. There is no wonder that farming is unprofitable under such circumstances; it would not be lucrative if no rent had to be paid for the land. It is not suggested, however, that none should be paid, for many an example proves that low rents are not conducive to high farming, for more often just the contrary is the case.

We rush on, and after passing through the yellow zone about Luton better land, or at any rate, far better farming, is seen. Most of the Wheat looks well, not a few of the fields excellent, and weather permitting a satisfactory yield may be anticipated. Barley and Oats are less promising, many fields being both short and thin, only a few having a full and healthy aspect. Beans and Peas are generally highly promising, the growth being ample and blossom plentiful. With favourable weather for setting the crops will be good, as there is a welcome absence of the black fly, which has often such a disastrous effect on the former crop. Potatoes, except those that were evidently planted late, look remarkably strong and healthy; indeed in this respect they could not be surpassed. Dry weather, however, is now wanted, for should the rains, which have been so frequent of late continue, and a high temperature at the same time prevail, the devastating murrain is certain to make its dreaded appearance. Other root crops, such as Mangolds and Swedes are regular and apparently healthy—a vast improvement on last year; while the Turnips appear to be coming up freely, and the showers have prevented the attacks of the "fly" which is so ruinous in hot dry weather.

From Kettering to Manton the scene changes. Not only by this route is the journey from London to the great towns of the north shortened by half an hour, but one of the most beautiful "bits" of pastoral country traversed that is to be seen in the kingdom. Far as the eye can reach is a rich panorama gently rising and receding until it merges in the misty horizon, which is broken by distant hills. In this tract of grazing land extending almost to the Trent the herbage is fresh, and apparently sufficient for the large herds and flocks with which it is depastured. The animals in this district are numerous and have a healthy sleek appearance indicative of a thrifty condition. Beyond doubt there are more animals in the pastures now than there were last year at this time, and they are also in much better condition. As the

Trent valley is reached meadows again prevail, the grass crops being good, but yet green. The ground, naturally moist, has been rendered too wet for haymaking by recent rains, and in places has been temporarily inundated. The rains in this district and northwards have been much heavier than in the south, and the crops are much later.

Altogether agricultural prospects are decidedly brighter now than they have been for a long time past, and it is ardently to be hoped that we are on the threshold of "better times" for those engaged in the most important of all industries—the production of food for our dense population.

POULTRY NOTES.

THE POULTRY CLUB.—The Committee of this Club were lately severely blamed in some quarters for declining to give a decision upon the general management (or mismanagement according to a complainant) of the Hemel Hempstead Incubator Contest. The Committee having no power to summon witnesses or to put them on oath, found it impossible to sift satisfactorily a mass of contradictory assertion. In a sensible and straightforward manner, as it seems to us, the Committee candidly pointed out the reason of their inability to adjudicate generally upon the case, and confined themselves to exculpating the accused from all *mala fides*. Curiously enough the Jockey Club is at the present moment in exactly the same difficulty upon the intricate and curious question of the identity of this year's winner of the Derby. The documents, it seems, which should throw light on the subject, fail to do so, and the Club has no power to examine witnesses on oath.

POULTRY v. RAILWAY COMPANIES.—Certain railway companies have long been the enemies of exhibitors of poultry and Pigeons. They refuse to be common carriers of poultry, and attempt to force those who consign live birds to them to sign a declaration to the effect that they do so entirely at their own risk. We have always believed these byelaws, to which officials point as if they were Acts of Parliament, to be entirely *ultra vires*. From a common-sense point of view, having regard to the immense powers given to railway companies, and to their having thereby superseded all other modes of conveyance, it would seem that they are bound to be common carriers of poultry. The Poultry Club took legal advice on the point, but failed to get a definite or satisfactory opinion. We think that fanciers who have been the victims of such byelaws should take heart on reading a decision of the Court of Queen's Bench delivered last week, by which one of the most usually accepted byelaws—viz., that a passenger who gets into a train without a ticket must pay from the starting point of the train, is entirely *ultra vires*, and so invalid. If byelaws for which there seems in common sense some reason are invalid, surely such absurd ones as those quoted above are likely to be so.

POULTRY HOUSES.—Poultry-keepers should look to the roofs of their poultry houses. We always find poultry even more liable to contract chronic illness from any damp or drip in summer than in winter. Dry spring winds often cause felt to crack, and then violent showers, such as we have been having of late, make their way into the houses. A zinc capping is a good top to a felt roof.

SUMMER POULTRY SHOWS.—These seem as numerous this year as ever. When they are held in tents and last but one or two days they cause little harm or fatigue to the birds, and are interesting as showing who are the most skilful rearers of fine early chickens. It must not, however, be thought that these forward chickens will, as adults, necessarily be any finer than many which are not yet half grown. Among the best schedules before us are those of shows to be held at Cardiff on July 27th to 29th; Ilminster, August 5th; Leicester, July 28th and 29th; Ormskirk, August 25th; and Crewc, September 2nd to 6th.

POULTRY SHOW DATES CLASHING.—We regret to find that it was impossible to alter the dates of either the Oxford Poultry Show or that in connection with the Dairy Show at the Agricultural Hall. Oxford has now for many years held the place of the first great chicken Show, and so we hope that the Dairy Show Committee may in some classes admit adult birds, and so to some extent diminish the loss which must necessarily accrue to both from this clashing of dates.

BRIGHTON POULTRY SHOW.—The Committee of the Sussex County Poultry, Pigeon, Rabbit, and Cage Bird Society intimate that they have changed the dates of the Brighton Show to the 16th, 18th, and 19th of October in place of those previously announced, as Birmingham Show takes place on those dates. They also solicit the support of fanciers with regard to cups and subscriptions, as they have greatly increased the classes. Classes will be made for any special varieties if twelve entries are guaranteed. Members joining the Society from July 1st have the privilege of sending pens at half entry fee, and also have two admis-

sion tickets. All communications to be sent to—T. R. CUCKSEY, *Chichester, Sussex.*

VARIETIES.

GLOUCESTERSHIRE POULTRY SHOW.—A first and most successful show of Poultry and Pigeons was held in the Town Hall of Newnham, Gloucestershire, on Thursday in last week. The poultry numbered 125 pens; the Pigeons, which were very superior, nearly 250 pens. The Carriers, Jacobins, and Dragoons were particularly good. The Judge was Mr. O. E. Cresswell, who had travelled without halt from Naples to fulfil his engagement.

— **MARTINS' NESTS.**—A correspondent, L. Cherry, asks if any of our readers can recommend any means to prevent the martins building under the eaves of houses.

— **THE ANTLER MOTH.**—There has been a swarm of this insect in Tatton Park, Knutsford Park, which has destroyed every blade of grass over a great extent of ground. The rooks have now attacked them and are rapidly destroying them. This insect is known to entomologists as *Noctua graminis*, and is particularly plentiful in Sweden, Norway, and Northern Germany, where it does great injury to the meadows. It has been stated on very good authority that at one place in Bohemia two hundred men were once employed for four days in removing the caterpillars from sixty bushels of soil, twenty-three bushels or 4,500,000 of the grubs being collected. Dressing the land with lime has been recommended as a means of destroying them, but rooks and crows appear the most efficient for the purpose.

— **ROYAL AGRICULTURAL SHOW.**—The forty-first annual Show of the Royal Agricultural Society now being held is considered one of the finest of the Society's provincial exhibitions. The Show was held in the same locality twenty-five years ago; but whereas fifteen acres of land then proved amply sufficient for all requirements, sixty acres are now comprised within the enclosure occupied by the implements and stock. Placing last year's Exhibition, which partook of an international character, without the category, the show of stock is the largest yet held, with the exception of that at Bedford six years ago. The total number of animals in the stock yard this year is 1581, against 1354 at Bristol in 1878, and 1305 at Liverpool the year before. The entries for the Kilburn Show were almost double this number. There are 487 horses, 434 cattle, the same number of sheep, and 146 pigs. The implement yard is less extensive than formerly, the exhibits in this department having fallen off very materially, owing mainly to the wide distinction that is now drawn in the Society's charges for shedding between *bonâ fide* agricultural articles and implements not exclusively for use in agriculture. The display of seeds is most imposing, such celebrated firms as Messrs. Suttons, Carters, and others, putting forth their full strength. The total value of the prizes this year is £5700, of which over £1000 has been contributed by the Carlisle Local Committee. The Council have arranged with the Aylesbury Dairy Company to repeat on each day in the week the display of the various systems of butter-making which excited so much interest at last year's Show, and the programme also includes occasional demonstrations of bee management.

— **INSTRUCTION IN AGRICULTURE.**—The Committee of Council on Education, South Kensington, have issued the following memorandum:—It having been represented to the Lords of the Committee of Council on Education that many parts of the kingdom are still in ignorance of the system of aid to the formation of classes for instruction in the principles of agriculture afforded by the Science and Art Department; that the supply of teachers who have obtained the necessary qualification to earn payments on results is very limited; and that a strict adherence to the rules of the Science Directory, which require that in order to obtain aid classes must be under the instruction of such teachers, would entail the delay of a year in the commencement of classes in this important subject, My Lords decide that Secs. 34 and 36 of the Directory may be relaxed for this year in the following manner:—My Lords will be prepared to consider an application from any committee formed in accordance with Section 10 of the Science Directory, to grant a temporary qualification to any person selected by it as fitted to teach the principles of agriculture, and, if such application be found satisfactory, will

permit the teacher to earn payments on the results of the examination in May, 1881, on the condition that this provisional qualification shall then determine, and that the only teachers who can after that date be recognised as qualified to earn payments on the results of their teaching in this subject will be such as have complied with the ordinary rules. In making the application the committee must show that there is no technically qualified teacher in the locality who could be employed to instruct the class, and also state the grounds on which the proposed teacher is considered to be really capable of giving instruction in agriculture, by his knowledge of chemistry and other sciences bearing on the subject.

— **THE HARVEST IN RUSSIA.**—A recent telegram informs us that as a consequence of the defective harvest prospects the question is discussed of forbidding the export of Wheat partially, if the deficiency be confirmed in the south of Russia, and a general restriction if the deficiency extends to other parts. Founded on reports from forty-eight provinces, this year's crop is estimated to be 39,717,800 quarters less than that of 1878.

ARTIFICIAL COMB FOUNDATION.

HAVING had considerable experience the last three seasons in the use of artificial comb foundation, and the subject having been frequently referred to in this Journal, I wish to state my ideas on the subject. I have found it alone uniformly successful when used simply for guide comb. For this purpose it is invaluable, nor does anything equal it, not even bee-made comb saved for the purpose however carefully introduced. Chiefly it is useful as guide comb in bar-framed hives. I find that a strip of it the whole length of the bar, and well cemented by running a slender stream of hot melted wax on both sides of the strip, is a specific against irregular combs. Every bar should be so treated, the comb foundation being put exactly in the centre of the bar the whole way. Nor do I find any "sagging" if it be not more than 1½ inch deep, or at most 2 inches. That this small piece of guide comb is an immense help to the bees will be acknowledged at once, when it is observed that an ordinary Woodbury bar-frame with a piece only 1½ inch deep will give over two thousand cells.

I have tried whole pieces applied carefully according to the directions of experts; but, whether so applied to the bar or in ways of my own devising, they will sag and twist about, and in very few instances have I been even tolerably successful with any pieces larger than those mentioned above. I should never think of employing them in any other way, least of all to tempt bees to work upwards. In former days, when I worked bellglass supers, I generally gave my bees some clean pieces of their own comb to start with, which I contrived to fix in such a way that a bit of the comb ran downwards through the hole into the hive below. This set them to work immediately, but I always found that when they had built up the comb a few inches into the bellglass it soon toppled over according as the weight of honey introduced became too heavy. This would happen even though the ingenious architects were most careful to broaden the base of their structure pyramid fashion. I used to enjoy watching the clever way in which they set to work to remedy the mischief; first by removing the superabundant honey so as to lighten the weight, and then by most ingenious buttressing of the fabric. I have long ceased to use these bellglasses because of the great labour and inconvenience to the bees which they occasioned, the slipperiness of the glass being one great evil. For profit wood or straw are the best materials for supers.

I have recently had very interesting evidence both of the value of artificial comb foundation and of the great help it affords the bees. A fine swarm issued from a Woodbury soon after twelve o'clock yesterday. It was hived in a similar box with bar-frames, eight of which were furnished with the strips of guide comb as described above. Here were given them foundations of about 16,000 cells. The day was splendid, and, as the hive was put in place of the parent Woodbury, of course nearly the whole adult population was at work in the course of the afternoon and this morning (June 26th). In the afternoon of yesterday I examined the old Woodbury, took out every comb, and cut away as many as eleven royal cells. This done I set the hive over the box occupied by the swarm. So they passed the night. At eleven this morning I again took off the parent Woodbury, and, after removing the box containing the swarm, replaced the Woodbury as it was before the swarm issued. The swarm-box was next examined, every bar-frame taken out, and the bees shaken down from each bar upon the Woodbury's top with all its holes open. This done I replaced over it two Lee's supers, in which the bees had been

working before the issue of the swarm. All this took about an hour. Since then work has been going on as if nothing had happened; the supers are fuller than ever, and I trust there will be no more swarming.

This evening curiosity has moved me to examine the box occupied by the swarm for about twenty-two hours. I have also counted the new cells which during that time the bees have added to the pieces of comb foundation; they amount to over 2650. Besides this all the 16,000 foundation cells have been elongated, and a quantity of honey placed in them; also the queen had laid a lot of eggs. They would probably have worked much more in the new box had it not been for my having placed the Woodbury over them, into which I found this morning that the majority of the bees had ascended, as I expected they would.

This gives some idea of the rapidity with which bees can work, but I confess I was surprised to find it was so much greater than I had imagined.—B. & W.

As I may fairly claim to have my say in the discussion on the merits of comb foundation now going on in our Journal, I make no excuse for departing from my usual rule of avoiding controversy in these columns. Like Mr. Cheshire I have been experimenting in various ways with sheets strengthened, by the introduction during the process of manufacture of various strengthening materials. I have embedded in the heart of the sheets threads of silk and raffia, and strips of parchment and tinfoil, and generally with satisfactory results. My aim has been to devise something that might enable us to fill the frame entirely, at least from side to side, and render impossible the risk of breaking down when new swarms are introduced among full sheets. But although I have had excellent results so far, I cannot claim any special advantage in sheets so strengthened, seeing that plain ordinary sheets have uniformly done just as well. The general result of my experiments is a conviction that for ordinary purposes strong well-made foundation without any strengthening material is as good as any. I am confirmed in this by the uniform testimony of my numerous correspondents. Only the other day I received a letter from an Irish Church clergyman who uses the large Langstroth frame, and whose experience may therefore be regarded as affording a severe test of the value of foundation. He says, "It is satisfactory to be able to say, that having used about two hundred sheets of your foundation, I have not had more than one (and that through my own fault) either broken down, torn, or distorted; and I look with contempt upon wired and wooden foundation."

Mr. Cheshire does not give the results of his experiments with plain unstrengthened sheets, but I feel confident that had he done so it would have confirmed my opinion that the supposed advantages of rakes, threads, &c., are quite immaterial compared with the expense and trouble of fussing with them. I think, therefore, that bee-keepers may still possess their souls in patience and content themselves with what in experienced hands has hitherto yielded such satisfactory results.

I feel truly grieved to have to advert, as I feel bound to do, to the remarkable notes on page 506 in the issue of June 24th from my friend Mr. A. Pettigrew. More than a year ago the world of bee-keepers learned with satisfaction that Mr. Pettigrew had so far yielded to modern ideas as to obtain 10 lbs. of comb foundation for experiment. Though somewhat late in the day the results have by many been eagerly looked for. Being informed how he proposed to fix his sheets in supers—viz., by wedging them between sloping sides—I wrote him privately, warning him that only failure could result, and enclosing printed directions for the proper fixing of the sheets. But, not content to tread in the footsteps of other experienced men, Mr. Pettigrew sets to work in a fashion that is marvellous indeed. He attempts to stand a rope on end, and invites the small boys to have a climb; down comes the fabric, boys and all, and at once the verdict goes forth, "Ropes are of no earthly use unless they can be made to stand on end." He builds a structure on a base one-sixteenth of an inch broad, and because it topples over under superincumbent pressure he is surprised. Now, this is really trifling both with science and Nature. Ropes and chains are made to be suspended, and in that position may bear their tons. In a state of nature bees never build their delicate combs from the floor upwards, but from the ceiling downwards. Still, if Mr. Pettigrew will insist on reversing Nature it is satisfactory to know that wondrous art has just in time come to his assistance in the form of wooden foundation. Mr. Abbott will doubtless be delighted to supply Mr. Pettigrew with samples for experiment, and the world will anxiously await the result.

I do not know that I would have thus noticed your correspondent's wonderful experiments were it not for his challenge that

"others" should answer why his foundations thus toppled over, and his innuendo following, "if they are made of pure wax." It is well known that the foundations in question were obtained from me. They were of the thinnest and whitest material, such being requested. That they failed under a test they never were made to stand, will not suggest to any experienced bee-keeper the least idea of adulteration; yet this is hinted at. Now, so confident am I of their purity that I declare myself ready to pay the expense of analysis by a public analyst should the decision be an adverse one, and I hope Mr. Pettigrew may thus set his mind at rest on the matter. The immense importance of comb foundation to bee-keepers makes it desirable to obtain all the light we can upon the best form to use and the way to use it. Let others report results whether adverse or favourable. Especially should those who have had years of experience come to the front now. Let them, however, learn before committing themselves to print, that it is just possible that any such failures as those referred to may be the result of their own mismanagement.—WILLIAM RAITT, *Blairgowrie*.

OUR LETTER BOX.

Swans (*Cuckfield*).—We do not think that they feed on fish. They are known as feeders on aquatic plants and insects. The fish in your pond may hide from the swans. If you went to the pond at night with a light you might see if the fish came to it.

Mangold Leaves Blistered (*R. S.*).—The leaves are infested with one of the leaf-miners—the maggots of a fly of the Dipterous order, which punctures the leaves and deposits eggs in them, the maggots which succeed feeding on the parenchyma or pulp of the leaves and often quite destroy them. If you hold up a leaf to the light and examine the papery white patches, these maggots will be easily discernible. In one of the leaves you have sent, the freshest, we found four in the space of a square inch. From the more withered leaves the maggots had escaped, no doubt changed into the pupa state, and entered the earth to undergo their transformation to the chrysalis form and produce more flies. The leaf-miners are most destructive insects, and when very numerous almost ruin the crops. Some of the species attack Turnips persistently; indeed this form, until the present season has been more common than that affecting the Mangolds. Unfortunately we know of no other remedy than gathering the leaves immediately any blisters are seen and burning them. It is not safe to give the leaves to animals, and to permit them to remain and shrivel is to increase an insidious and destructive pest. Some Mangold crops have been almost destroyed this year by the maggot; indeed we have heard of some being ploughed up and the land sown again; but this we think a mistake, as the next crop affords food for the perpetuation of the enemy it is so desirable to banish.

REMARKS.

- 4th.—Rain in early morning, generally fine and bright during the day, overcast with heavy clouds about at intervals, fine evening.
 5th.—Fine and bright before noon, afternoon overcast, fair evening.
 6th.—Overcast and gloomy, very slight sunshine, rain in evening.
 7th.—Dull cool morning, showery all day, slight intervals of sunshine, fine in evening.
 8th.—Very bright in early morning, shower at 10 A.M., very heavy rain for about a quarter of an hour from 1 P.M. during a thunderstorm, fine afterwards.
 9th.—Dull morning, heavy showers between 9 and 10 A.M., fine and bright afterwards.
 10th.—Dull in forenoon, heavy shower between 1 and 2 P.M., fine afterwards.
 Temperature below that of the previous weeks, and air damp with occasional drenching showers.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 14.

OUR market is well supplied with all classes of goods, prices generally being lower. The soft fruit is well cropped, being on the whole short with the exception of Raspberries, which meet with a slow demand.

MEALY BUG IN VINERIES.

HERE is no insect with which the gardener has to contend that causes greater annoyance and disappointment than the mealy bug, and certainly none of the many pests that inhabit fruit and plant houses are so difficult to eradicate as it is. It has been asserted that when the bug once takes possession of a house its entire extirpation is impossible ; such may be the case, but my experience points in the opposite direction. At the same time I admit that extreme measures have to be adopted for thoroughly clearing it out, which I believe is not possible at the first attempt, but it must be closely watched for some time afterwards. In Peach houses it is much easier to be disposed of. One good cleaning of the trees and the house in winter, as well as removing the surface soil during the dormant season of the trees, with the syringe constantly being employed when they are in active growth, soon destroys the insects, which do not like water syringed upon them with force, and wherever it is applied regularly and sufficiently the bug will be found to diminish rather than increase. In vineries if the Grapes are to retain their bloom syringing would be entirely out of the question until the fruit is gathered.

If vineries are not badly infested, the Vines should have all the loose bark removed after pruning, and be well washed with fir-tree oil at the rate of half a pint to three gallons of water, or with Gishurst compound. Paraffin oil is certain death to the mealy bug, but should only be employed by experienced hands upon Vines, for it will kill the Vines as well as the bug if not judiciously applied. It is good for cleaning the woodwork, but must be diluted with water, and should be applied with a brush. The surface soil, if the border be inside, should be removed and fresh soil supplied. The walls should also be washed with hot lime mixed with paraffin oil. Even if every part of the house and Vines is thoroughly cleaned the pest will make its appearance again after the Vines have started into growth and the season has advanced. The early spring or summer, according to the time when forcing commences, is when the insects increase. Their destruction can be accomplished when they are first seen creeping upon the Vines, which should be examined sedulously and perseveringly. If left until the foliage expands the work of searching for the enemy is almost useless ; but if the search is thorough and continuous early in the season, and the insects are killed as they appear, they will considerably decrease, and in a season or two the house will be entirely free.

Vineries that have become badly infested require a large

amount of work to thoroughly clean them, and the best and most satisfactory system that can be adopted is to remove the Vines and all the soil, drainage, &c., from the border. The wood and wirework should be cleaned with paraffin oil, and afterwards well painted. The brickwork if previously lime-washed should be cleaned, and the walls, paths, pipes, and other portions of the house where practicable washed with spirits of salts. This if well and thoroughly applied will destroy any bug that may be concealed. This being done fresh drainage should be employed, the border remade, and fresh Vines planted. Clean Vines must be obtained, and it is far better to wait and start by raising Vines from eyes than to plant infested Vines. After planting constant attention must be paid for fear the enemy should again appear, for probably it will do so, but in small numbers, and must be promptly removed. A house here that was badly infested was treated as described, and the mealy bug appeared again some time after the Vines were planted. They were planted in July, 1878, but before winter no trace of any insects was to be seen, and the house is up to the present time thoroughly clean. Some may probably conclude that if bug in small quantities can be eradicated from Vines, it can also be banished from houses badly infested. Experience does not support this view of the matter. When the insects are few they are upon the Vines principally, but when numerous they are in the walls, in any crevice of the woodwork, under the paint if possible, and even upon the strong roots of the Vines under the surface of the border. Vineries infested as described may be extreme cases, yet such cases have existed and do exist, and a thorough clearing-out and cleaning as above indicated is the only means of stamping out this, one of the greatest enemies of the gardener.

When mealy bug exists upon Vines the insects are sure to make their way into the bunches if every precaution is not taken to prevent them. Pieces of white paper should be cut circular in shape (the size depending upon the size of each bunch of Grapes), with a small hole in the centre, a slit being made from this to the edge for admitting the footstalk, by which means the paper can be fixed over the bunch. A small portion of cotton wool should be placed above the paper round the stem of the bunch. This will prevent the insects crawling down the stem through the hole in the paper to the bunch. It will be found that the cotton wool is a good trap for the pest, and should occasionally be removed and fresh wool supplied. The cotton wool alone will prevent the insects going into the bunch to a certain extent, but better still the paper and wool combined. The paper shield also prevents many insects that fall from the Vine going into the bunches, but a few will probably find their way there, and if allowed to remain for a time they increase rapidly. The bunches should, therefore, undergo a rigid scrutiny at least once a week. Bunches that are already infested must be cleansed as they are cut, and if the insects are removed with a feather or small brush the Grapes are much more rubbed than if placed under a tap with a good force of water running through the bunches, which will remove the greater portion of the bug without much damage to the bloom if the work is carefully carried out. The Grapes must be afterwards hung up where air can play freely about and through the bunches to dry them. If any insects remain after the washing they can be removed with a small brush. The paper collars do not look attractive in a vinery, but they assist considerably in keeping the pest from the bunches,

especially if at the same time it is constantly sought for upon the Vines and destroyed.—WM. BARDNEY.

THIS most troublesome enemy is bad enough to cope with on plants, but on Vines it is most to be dreaded. Some years ago I took charge of some old Vines that were covered with the mealy bug insect, the bunches of Grapes being white with this dreadful enemy. We were obliged to wash the bunches before sending them to my employer's table. This washing of course disfigured the Grapes, still it was much better to wash the Grapes than to send them to the table covered with mealy bugs. I find nothing so successful in the destruction of this pest as tobacco juice. As soon as the leaves have fallen prune the Vines and scrape all the old bark from them, especially near the eyes. When the Vines are thoroughly cleaned of all the old bark paint them with tobacco juice. A second painting should take place, but with a composition of Clay's tobacco powder and sulphur mixed with softsoap water. This is the way I disposed of the mealy bugs. The house should be thoroughly cleaned, and the walls washed with hot lime.—H. CAKEBREAD, *Raymers*.

NEW ROSES.

OF the new continental Roses of 1877-8 and 1878-9, I have on my list eighty-three of the former, and eighty-one of the latter issue, making a total of 164 in two years, the list of 1878-9, perhaps, not being complete, as I find the names of Lacharme and a few of the other usual raisers wanting. If to those be added about thirty English varieties which I cannot classify correctly in years, and setting aside the continentals of 1879 and 1880, of which I have upwards of seventy already catalogued, we have new Roses at the rate of something like one hundred per annum to test! This is indeed a herculean task, and hardly to be undertaken by a single firm or individual, and under the best of circumstances the matter must be a seriously costly one to the trade. It is, therefore, exhibitions like those held by the National Rose Association and at the Alexandra Palace which give special encouragement to the producers of new Roses by the liberal prizes offered; and the public are also largely indebted to them, as the unnecessary multiplication of mediocre and inferior varieties is advantageously checked.

At the Exhibition at the Alexandra Palace on the 10th inst. some thirty varieties of 1877 and 1878 were shown. Amongst these A. K. Williams (Schwartz, 1877) fully realised all that has been previously seen and said in its favour, and it will not be vaunting it too much to describe it as the perfection at length attained of the Charles Lefebvre type, for in form, substance, colour, and build it seems in all respects to be the perfect realisation of a Rose of this famous type; all its predecessors of the same apparent parentage, such as *Souvenir d'Adrien Balnet*, *Marguerite Brassac*, &c., being but beautiful copies of the grand but faulty original. The wood, however, of A. K. Williams is more thorny, and in that respect distinct from the type. A gold medal is due to M. Schwartz from somebody for this Rose! Of the same race Paul Jamain (H. Jamain, 1878) appears to be a fine stiff-petaled, imbricated dark Rose, and in the absence of A. K. Williams might be welcomed with *éclat*. As, however, Paul Jamain is a year junior, we must wait before consigning it to mediocrity. *Duchess of Bedford* (W. Paul & Son, 1877) was well shown in several stands, and in brilliancy of colour, form, substance, and general appearance comes between *Général Jacqueminot* and *Sénateur Vaisse*. *Jules Chrétien* (Schwartz, 1878) is another fine dark of the Camille de Rohan family, but with more regularity of petal. The same may be said of *Souvenir d'Auguste Rivière*, a Rose, however, of more substance. *Mabel Morrison* (Broughton, sent out by Mr. Bennett, 1878) is certainly the purest white H.P., and being thin, although of good form, ought to seed and become the parent of a really good white H.P. *Constantin Tretiakoff* (H. Jamain, 1877) as exhibited did not fulfil the expectations I formed of it last season. *Mdlle. Marie Verdier* (E. Verdier, 1877) is a very fine large-cupped purplish pink Rose of good substance, and, opening freely, promises well for a good exhibition variety. Charles Darwin, a dark red seedling of my own raising, and sent out by Messrs. Paul & Son in 1878, will not, I venture to hold, be a disappointing Rose, as it combines fine form and depth of colour with wonderful growth and freedom of bloom. It will be seen that amongst those selected as above the majority are dark; and this is doubtless in accordance with the public taste, for where one light Rose meets with admirers the dark are preferred by the many.

Amongst the noticeable and promising new varieties which are just leaving the hands of the grower, or only provisionally exhibited, were *Duke of Teek* (Paul & Son, 1879), the brightest of the Duke of Edinburgh family, if Mr. G. Paul has not surpassed it by his *Brightness of Cheshunt*, a Rose of a similar type not yet sent out. *Pride of Waltham* (W. Paul & Son), light rosy salmon of the Eugénie Verdier type, but rather lighter in colour and better filled. *Mrs. Harry Turner*, a seedling of my own from Charles Lefebvre × Alfred de Rougemont, now being sent out by Mr. Turner, a very brilliant-coloured imbricated Rose of first-rate form and good growth. As Mr. Turner has kept this Rose until he has thoroughly tested it, and ultimately honoured it with the family name, I take it to be a mark of his confidence in the variety, which is certainly a very taking one. In addition, *Countess of Darnley* (Paul & Son), as shown, of a distinct rosy mauve tint, and good form and substance; A. McKenzie (from the same raiser); *Lady Sheffield* (W. Paul & Son); the Rev. W. H. Stomers (Laxton, in the hands of Mr. Turner), raised from C. Lefebvre × Princee Camille de Rohan, and nearly intermediate between the parents; and the Rev. A. Cheales (Cranston), are all promising, and will probably appear again on the scenes.

I had almost omitted the new Teas *Madame Lambard* (Lacharme, 1877) and *Innoceente Pirola* (Veuve Ducher, 1878), both of which were well shown. I did not, however, observe *Madame Welche* (of the same raiser, 1877), which has proved with me a fine hardy Tea.

Mr. Bennett's seedling Hybrid Teas were not largely exhibited; but Mr. Prince, who as usual was foremost amongst the Teas, showed me fair blooms of *Viscountess Falmouth* and *Beauty of Stapleford*. These Roses as grown at the Experimental Garden on the standard Briar, notwithstanding they have the growth and wood of the Teas, have proved themselves hardy and free growers. With only slight protection they survived the past winter where most of the Teas succumbed. They are also showing bloom finely.—T. LAXTON, *Bedford*.

STRAWBERRIES FOR FORCING.

RUNNERS layered in small pots will now be well rooted and ready for placing in the fruiting pots, which for the early varieties, such as *Pioneer*, *Vicomtesse Hericart de Thury*, and *La Grosse Sucrée* should not be larger than 6 inches in diameter, 5 inches answering very well; but for stronger-growing sorts, such as *President* and *Dr. Hogg*, 7-inch pots are suitable, especially when the plants are not required to afford fruit before May or June, otherwise an inch less size of pot is preferable. A rather strong friable loam, the top 3 inches of a pasture taken off with its turf in spring and stacked, chopped up moderately small, adding to every six barrowfuls one of decayed manure, a sprinkling of bonemeal in place of sand, the whole being thoroughly incorporated, forms an excellent compost. The pots should be clean both inside and outside, one large crock being placed over the hole, and about an inch of smaller crocks will be sufficient drainage, placing the rougher portions of the compost over it. The soil beneath and around the ball of the plants should be rammed hard, keeping the plants rather high in the pots, but the soil should be kept about three-quarters of an inch below the rim to admit of efficient watering. After potting place the pots in an open situation upon a hard base, ashes answering very well, and allow sufficient space between the plants for the due exposure of the foliage to light and air. With proper attention in watering, the removal of runners and weeds, the plants will grow vigorously and mature the crowns in good time, so as to become rested before it is required to place them in heat.—G. A.

A CHEAP PERENNIAL BORDER.

ABOUT this time last year I purchased and sowed a collection of seed of twenty-five perennials. With one or two exceptions the seedlings appeared thickly and grew strongly, and when larger enough they were pricked out in a prepared bed. In October as many of the plants as I required were transferred to a newly dug border which I wished to devote entirely to perennials. The border is about 60 feet long and 8 feet wide, and with the assistance of a few dozen bulbs (*Tulips*, *Crocuses*, *Anemones*, and *Narcissi*), it has been gay since the end of March. My border cost me altogether less than £2, and yet it has been entirely satisfactory, although the soil is not rich and the position is very exposed.

I have now the following plants in bloom:—In the two back rows *Anchusa capensis*, which is one mass of blue flowers; it has been equally fine since the end of April, and bids fair to continue for another month; *Antirrhinums*, tall varieties of many brilliant shades of colour; perennial *Lupins* now commencing flowering,

besides many Foxgloves, some curiously marked, but none so beautiful as the pure white. Behind all these plants a row of Hollyhocks will come into flower in August, when other perennials begin to fade. In the front rows I have had a rich display of Polyanthuses, followed by the double Dutch Anemones and the late Tulips, Indian Pinks being just expanding their flowers. The edging plant employed is *Arabis albida*, which was very beautiful in early spring.

Altogether I am more than pleased with the success of my first trial with perennials, and if others feel inclined to follow my example they can have a floral treat for eight months in the year at little expense. I have not mentioned half of my plants. The most beautiful just now is, I think, the *Oenothera taraxacifolia* lutea, so favourably mentioned on page 474 of the last volume of the Journal; mine are planted next to the *Anchusa capensis*, and the contrast between the bright blue of the one and the rich yellow of the other adds much to the beauty of the border. I have, I think, thirty distinct colours and markings in my Sweet Williams, all from one small packet of seed.—P. C.

CARNATIONS AND PICOTEES—SETTING-UP AND JUDGING.

A FRIEND of mine, speaking on the subject of setting-up the flowers for exhibition, says that if prizes are to be won on the exhibition table they must first be won with the flowers in the mind's eye of the exhibitor when on the plants. This to young growers is generally the great difficulty, as they frequently cut flower after flower, thinking each one the best, until the number grows so large that it is nearly impossible to decide which are the best flowers. In many cases some of the best are left out, where if a little calculation or forethought had been employed not more than one-third of the blooms need have been cut. Before cutting the flowers it is always best to calculate how many flowers may be required. In selecting the flowers it is not always wise to take the largest, as size alone will not win, and it generally happens that if a flower is large it is old as well, and will frequently collapse before coming to the exhibition table. The consequence is that most probably the stands will have to be rearranged, because, as will often occur, a flower of a different class has to be substituted in the place of the one collapsed. My advice is always to select bright young flowers, as they will continue to grow and improve after being cut.

Before cutting the flowers it is a good plan to make out a list of the blooms required in their different colours, cutting each lot separately before proceeding to cut the others. Let the full number of flowers be dressed and carded before proceeding to arrange the stands. The corner flowers should be the best in the stand, as they are always most seen. The following is a good method of setting-up a stand:—In order to have the different varieties or colours of the flowers, so as to act as a foil or contrast to each other, it is always best if a high-coloured flower, say scarlet bizarre or crimson bizarre, is followed with a pale or soft-coloured one; as for instance pink and purple bizarre, rose flake, or purple flake.

STAND OF TWELVE CARNATIONS.

Scarlet Bizarre	Rose Flake	Crimson Bizarre	Purple Flake
Scarlet Flake	Purple Flake	Scarlet Bizarre	Scarlet Bizarre
Pink and Purple Bizarre	Scarlet Bizarre	Rose Flake	Crimson Bizarre

The above was the mode in which a stand was exhibited at one of our National exhibitions. I thought at that time it was one of the handsomest stands I ever saw. If, however, a flower of super-excellence is amongst the lot I prefer placing it in one of the middle tubes in the top row if a flower of large size, or in the second row if of medium size. This is a strong point in exhibiting a good seedling, and is practised by all the leading growers. In setting-up Picotees the four corner blooms should if possible be heavy, at the same time a heavy flower should be always followed with a light or medium-edged one. The following were exhibited in a stand at one of our National exhibitions, and in my opinion left nothing to be desired:—

TWELVE PICOTEES.

Heavy Red	Light Rose	Medium Red	Heavy Purple
Light Rose	Heavy Purple	Heavy Rose	Light Red
Heavy Purple	Light Purple	Heavy Red	Heavy Rose

After placing the flowers in the stands it is necessary to examine them carefully to see that they all face one way, and stand at a uniform height or nearly so, as the flowers show to greater advantage. It will always occur that some flowers will be some-

what flatter than others, and be lower. It is a good plan to prop up the low flowers by placing something under the card—say a little cotton wadding, or even paper, so as to elevate them to the height of the others in the stand. The water in the tubes should be fully 1 inch or more from the top of the tube, so that it will not get into the calyx amongst the petals or wet the collars. Many growers have holes pierced through the sides of the tubes, so that the water may run off to the depth before stated. Never use a dirty or coloured card, as they always spoil the effect of the white in the flowers, whilst a card which is creamy always spoils the appearance of a light Picotee. The best place I have found for obtaining the cards is from G. Meek, Crane Court, Fleet Street, London.

Judging.—In judging stands of flowers, as defined by Mr. Dodwell, errors may and will be easily committed if the flowers are judged by comparing one flower with another, owing to the manner in which the flowers are placed. Taking Mr. Dodwell's illustration. "Suppose that two stands—A and B, each consisting of six flowers—are to be judged, and that each figure underneath denotes a flower and its degree of merit. If they chanced to be placed in the first position they will be equal.

A	3	2	4	3	4	5
B	3	2	4	3	4	5

But take the same flowers, and change their positions thus:—

A	3	2	4	3	4	5
B	4	3	5	4	3	2

It will be seen that B gains on four flowers, and A only on two, consequently the award is given to B; but similarly change their position again, and A gains on four, B on two; therefore the award goes to A. This is radically wrong in principle, and therefore must lead to error in practice. The sound rule is to compare each collection as a whole with its competing collection, and to determine its place by the result. Of course into this comparison analysis would enter, as it enters into the determination of the merit and place of the individual flower, which wins its place when rightly judged, as it is found to contain the higher quality, the better growth, the more symmetrical form, the brighter colours, the better markings, and the greater variety."

Selecting the premier flower in a collection is one of the most difficult tasks a judge has to undertake, and one that requires most care. In large exhibitions, as the National for instance, where there are perhaps two or three sets of judges, each set should be requested to select the best flower in the collections which they have judged and to mark the same, so that they can be easily distinguishable by the judges who may be appointed to define the premier bloom. As the judging for premier is now done it is a wonder to me that ever a premier is found, besides delaying the opening of the exhibition. The mode as practised now is for the judges and exhibitors to go in a body seeking through the stands for a premier, when the chances are that what is premier will be passed by. Take for instance the judging at the National Exhibition last season. The premier flower beyond doubt was a seedling scarlet bizarre of Mr. Dodwell's called Robert Lord, a magnificent flower, perfect in colour, form, and marking, particularly good in all points, and for a scarlet bizarre of good size; whilst the flower to which the award was given only surpassed it in size. Its faults were deficiency of flake and broken markings when compared with the markings of Mr. Dodwell's flower. It is very rare indeed that a flake is capable of winning a premier prize against a bizarre, and as yet it is only in the scarlet bizarres that we can with certainty count on finding the best flower in the exhibition. The crimson bizarres generally, although having fine colours when newly raised, are very liable to become patchy in colour as the variety becomes older. Take for instance Eccentric Jack—the best of Wood's batch—how rarely is a really good flower of it seen. One time it is pale in colour, deficient in bizarre, or perhaps some petals are deficient of nearly both the colours. I hope that we shall before long have a crimson bizarre sufficiently good and constant to win first honours, and prove a second Admiral Curzon in its class, which up to now has won more premiers than any other variety; and yet, although fast approaching forty years of age, with me last season it produced flowers as fine as I ever remember to have seen them.

In judging for the premier bloom in Picotees it is a much easier task to select the best. The points to be noted are pure white grounds, broad smooth-edged petals, with a broad solid band of colour running evenly on the edge of each petal, and free from spots or bars if a heavy flower; whilst if a light one the colour should be solid on the edge without any break in it. This is generally the great fault of many of the light edges; they appear as if serrated on the edge, whilst it is only the colour which is broken. It is, however, generally amongst the medium-edged flowers that the premier flowers are to be met with. Take for instance Zerlina

(Lord), which when in its best condition cannot be surpassed.—
GEORGE RUDD.

STRAWBERRY PAULINE.

OUR experience of this variety of Strawberry is very different from the description you give of it in your last number. We grew it three seasons, and as it did not improve we discarded it. It is early, and that is all we can say in its favour. It is ugly as regards shape, and as to flavour few would taste it a second time. We claim to have had some successful experience as regards Strawberries, having introduced such standard kinds as President, Dr. Hogg, Sir Joseph Paxton, Frogmore Late Pine, and others.—CHARLES TURNER, *Slough*.

[We stated that Pauline would possibly not succeed in all soils so well as at Cheshunt. The fruit sent to us from Cheshunt was just as represented in our engraving on page 53, and was for an early Strawberry delicious. It is evident that this variety does not succeed at Slough. Strawberries are capricious. We know a garden where even the free and useful President is worthless, and more than one where Dr. Hogg refuses to flourish; yet these are valuable varieties.—EDS.]

NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW. MANCHESTER.—JULY 17TH.

AFTER such heavy thunderstorms as have lately prevailed it was not surprising to find that the lower petals in nearly all the blooms that were staged showed signs of the damage they had received during the early development of the buds. The Show was held in the Botanic Gardens, and notwithstanding the absence of some of the well-known competitors the Exhibition was a great success. The diminution in the number of exhibitors was doubtless due to the difficult season Rose-growers have had to contend with, and not to any lack of energy on their part. However, in spite of the unripened state of the wood last autumn and the downpour of rain for some days previous to the Show

the blooms were of exceptional quality both as regards size and colour. The Roses were arranged round the sides and ends of the large conservatory and on a table in the centre. Rows of small decorative plants were arranged between the classes so as to render the work of the Judges as easy as possible. The centre stage was arranged similarly with the addition of a row of larger plants down the centre of the table. The monotony that would have been displayed by a tent of Rose blooms was relieved by the system adopted; and the large plants, which also occupied various positions in the house, with quantities of creepers hanging tastefully from the roof contributed to the general effect. Dark Roses largely preponderated, and perhaps one of the finest collections ever exhibited at any exhibition of Alfred Colomb was staged by T. Jowitt, Esq., The Old Weir, Hereford; for colour, size, symmetrical outline and evenness, the blooms could not have been better. Messrs. Cranston and Co., Hereford, exhibited handsome blooms of their new Rose Mary Pochin, a fine, fresh, and excellent dark Rose, which was much admired. Mr. George Prince of Oxford staged Duke of Edinburgh in grand condition.

The schedule consisted of nineteen classes, six for nurserymen, eight for amateurs, and five open.

Nurserymen's Classes.—For seventy-two, distinct, single trusses, four collections were staged, the awards being in the following order—First, Messrs. Cranston & Co., King's Acre, Hereford; second, Messrs. Paul & Son, Cheshunt, Herts; third, Messrs. Davison & Co., Hereford; fourth, Mr. Wm. Rumsey, Waltham Cross. The first-prize collection contained some excellent blooms, fresh, fine in colour, large, and far ahead of any others staged in the same class. A few of the most conspicuous and noteworthy blooms were as follows—Mdlle. Marie Finger, La Francee, Marie Baumann, very fine; Mary Pochin, new, full, and a fine bright flower; Dingee Conard, Alfred Colomb, Niphetos, very fine, and perhaps the most magnificent bloom in the collection; Dupuy Jamain, Mdlle. Eugénie Verdier, Capitaine Christy;

Le Havre, Baron Haussmann, A. K. Williams, a beautiful bloom; Madame Lacharme, Mrs. Jowitt, a fine new Rose not yet in commerce; John Stuart Mill, Reynolds Hole, Etienne Levet, Souvenir d'un Ami, Comtesse de Serenye, Catherine Mermet, and Emilie Hausburg in fine condition. The second-prize blooms were much smaller, yet several were handsome, such as Souvenir d'Auguste Rivière, a very fine dark Rose; Marie Baumann, Brightness of Cheshunt, Comtesse de Choiseuil, a fine new Rose; Earl Beaconsfield, Annie Wood, Charles Lefebvre, one of the best coloured blooms in the Show; R. N. G. Baker, new; John Bright, Alba Rosea in beautiful condition; Camille Bernardin, Jean Ducher (Tea), Charles Darwin. The third-prize lot was also a good one. Sénateur Vaisse, Horace Vernet, Louis Van Houtte, Alfred Colomb, Reynolds Hole, Xavier Olibo were amongst the best blooms. The fourth collection had evidently been much dashed with the rain, and many of the blooms were small. For forty-eight, three distinct trusses of each, first, Messrs. Paul & Son, Cheshunt; second, Messrs. Cranston & Co.; third, Messrs. Davison & Co. Good blooms were staged, and the first and second collections were very near, and proved a difficult task for the Judges. The first lot contained fine blooms of Magna Charta, Charles Darwin, Catherine Mermet, Maurice Bernardin, Camille Bernardin, Niphetos, Marguerite Brassac, and Ferdinand de Lesseps. The second-prize stands had good blooms of A. K. Williams, Niphetos, Souvenir d'Elise, La France, Marie Van Houtte, Lord Macaulay, Duke of Edinburgh, Horace Vernet, and La Duchesse de Morny. In the third lot were fine blooms of Mons. E. Y. Teas, La Rosière, Auguste Neumann, and Comtesse de Serenye.

In the class for twenty-four distinct varieties, three trusses of each, Messrs. Cranston & Co. were again first, Messrs. Paul & Son second, and Messrs. Davison & Co. third. The other collection in this class was staged by Mr. Prince, Oxford, whose Roses were much injured by some delay on the line, and in consequence he had to discard many blooms that would otherwise have been shown, and doubtless strengthened his position. In the first-prize lot Beauty of Waltham, Exposition de Brie, Princess Mary of Cambridge, and Princess Beatrice were good; in the second stand Charles Darwin, Duke of Teck, and Dr. Andry; in the third Charles Crapelet and Duke of Wellington. In the class for twenty-four, distinct, single trusses, Mr. J. Griffiths was first with very fine blooms of Beauty of Waltham, Sir Garnet Wolseley, Mons. E. Y. Teas, Sénateur Vaisse (a very fine bloom), Louis Van Houtte, Madame Charles Wood, and a fresh and fine large bloom of May Quennell. Second, Messrs. G. Bunyard and Co., Maidstone. This collection had good examples of Richard Wallace and Edmund Wood. Third, Mr. Henry Frettingham, Nottingham. A bloom of Mabel Morrison in this stand was much admired. In the class for eighteen, distinct, single trusses (local nurserymen only), Mr. Yates, Heaton Norris, was the only exhibitor, and his stand was only considered worthy of a second prize. In the class for twelve Teas or Noisettes, distinct, single trusses, first Messrs. Cranston and Co. with a good even collection. Niphetos was a fine bloom; and Madame Lambard. Souvenir d'un Ami, America, Souvenir de Mons. Paul Neyron, Jean Ducher, good. Second, Mr. G. Prince with even blooms, including a good example of Souvenir de Madame Pernet, Souvenir d'Elise, Madame Berard, and Alba Rosea. Third, Messrs. Paul and Son, Cheshunt, Gloire de Bordeaux and Belle Lyonnaise being the best blooms.

Amateurs' Classes.—In the class for thirty-six, distinct, single trusses, Mr. T. Jowitt secured the premier award with highly meritorious blooms. The following were beautiful in form and colour—viz., Alfred Colomb, Le Havre, Exposition de Brie, Comtesse de Serenye, Camille Bernardin, Beauty of Waltham, Louis Van Houtte, A. K. Williams, and Maréchal Niel. Second, Mr. G. P. Hawtrej, Slough; Harrison Weir was a very good bloom amongst many others. No third. In the class for twenty-four, distinct, single trusses, first, A. G. Soames, Esq., Bourne, with a very good collection, including Etienne Levet, Sir G. Wolseley, Charles Lefebvre, and La Rosière. Mr. T. Jowitt was a good second, and had fine flowers of Fisher Holmes and La Duchesse de Morny. Third, Mr. G. P. Hawtrej with good blooms of Anna Ollivier and Madame Verlot. Fourth, J. B. Hall, Esq., Rock Ferry, with rather small blooms. In the class for twelve, distinct, single trusses, first, Rev. J. H. Pemberton, Havering-atte-Bower, with very fine blooms. Second, E. R. Whitwell, Esq., Barton Hall, Darlington. Third, Wm. Stubbs, Esq., Broad Lane, Nantwich. For six, distinct, single trusses, E. Mawley, Esq., Addiscombe; Wm. Stubbs, Esq., and W. Walters, Esq., Burton-on-Trent, secured honours in the order named. For six, distinct, single trusses of district-grown Roses, first, James Brown, Esq., Heaton Mersey (gardener, Mr. G. Gass); second, Wm. Brockbank, Esq., Didsbury; third, J. Davenport, Esq., Altrincham. For twelve Teas or Noisettes, distinct, single trusses, first, Mr. G. P. Hawtrej with very fine blooms, such as President, Caroline Kuster, Marie Van Houtte, Jean Ducher, Adrienne Christophe; second, Mr. A. G. Soames. Catherine Mermet and Caroline Kuster were again good. For six Teas or Noisettes, distinct, single trusses, first Rev. J. H. Pemberton; second, Mr. T. Jowitt. For six new Roses, distinct, single trusses, not in commerce previous to 1877, the only box was staged by Mr. G. P. Hawtrej, and he was awarded the first prize. The blooms included Countess of Rosebery, Harrison Weir, Richard Laxton, La Coquette, A. K. Williams, and Beauty of Stapleford.

Open Classes.—Twelve new Roses, distinct, single trusses, not in commerce previous to 1877.—First, Messrs. Paul & Son, Cheshunt,

with Penelope Mayo (full and good), Comtesse de Choiseuil, A. K. Williams, Constantin Tretiakoff, Magna Charta, Madame Gabriel Luizet, Charles Darwin, Leon Renault, and Paul Jamain. Second, Messrs. Cranston & Co. with Madame Chiverot, Mary Pochin, Princess Charlotte de la Tremouille, Wilhelm Kœlle, Duchess of Bedford; the remaining varieties the same as mentioned above. Third, Messrs. Davison & Co. with a good bloom of Pearl and Mrs. Laxton. For twelve single trusses of any Hybrid Perpetual (dark).—First, Mr. T. Jowitt with Alfred Colomb as alluded to above. Second, Messrs. Cranston & Co., with an excellent box of Marie Baumann. Third, Mr. George Prince, Oxford, with a fine box of Duke of Edinburgh. For twelve single trusses of any Hybrid Perpetual (light).—First, Mr. T. Jowitt with a magnificent stand of La Duchesse de Morny. Second, Messrs. Cranston & Co. with fine blooms of La France. Third, Messrs. Davison & Co. with much smaller blooms of La France. The other exhibitor was Messrs. G. Bunyard & Co., Maidstone. For twelve single trusses of any Tea or Noisette.—First, Messrs. Cranston & Co. with large fresh blooms of Niphetos. Second, Mr. G. Prince with Souvenir d'un Ami. For twelve single trusses of any yellow Rose the only exhibitor was Mr. Prince, who was awarded first with attractive blooms of Perle des Jardins.

Miscellaneous Exhibits.—Several boxes of Roses and some hardy shrubs in pots were exhibited by Messrs. Dickson & Robinson of Manchester; Messrs. Cranston & Co. exhibited a box of their new Rose Mary Pochin; Messrs. Paul & Son a very fine stand of A. K. Williams; Messrs. G. Bunyard & Co. a very good box of Ferdinand de Lesseps; Messrs. Davison & Co., White Cross Nursery, fine stands of Xavier Olibo and Marie Baumann. Mr. Samuel Barlow, Stakehill House, Chadderton, exhibited three hundred blooms of Persian Ranunculi, which attracted much attention.

Fortunately the day proved fine for the Exhibition, and large numbers of visitors assembled. Mr. Bruce Findlay efficiently conducted the arrangements of the Exhibition. The Judges were Rev. H. H. D'Ombraim, and Messrs. Jowitt, Hawtrey, Whitwell, Curtis, Cranston, G. Paul, Prince, and Herbert.

RHODODENDRONS NEAR LIVERPOOL.

SOME notes on Rhododendrons having recently appeared in the Journal, a few remarks as to how these handsome shrubs succeed near Liverpool may not be without interest.

There are not many places in Lancashire where they can be seen to greater advantage than at Grassendale Priory, the residence of Mr. Horsfall of Liverpool. Considering the very limited space at command, this collection, consisting as it does of over one hundred varieties, may be described as almost unequalled. The wet season of last year checked many of the specimens, the constant rain having produced a second growth when they should have been setting their flower buds, but still on the majority the trusses have this season been larger and in some cases more numerous than usual. Some of the largest were over at the time of my visit, and fallen and faded blooms of Alexander Adie and Old Port told of glories which were past for this summer. The latter, however, was well succeeded by Sir Joseph Whitworth, a large very dark variety with handsome foliage. There were several good specimens of white varieties in flower, of which Purity bore the palm both for size and colour, though some of the larger bushes of Minnie and Lady Godiva were very striking. About thirty new varieties have lately been planted, several of which promise to be unusually good. Surprise is a fine late one, with large light-coloured truss and dark-centred flowers; Kate Waterer, a splendid crimson with large yellow centre, one of the handsomest; Quadroona, Pelopidas, and Mr. John Kelk, all good pinks of different shades; while amongst the white and light-coloured varieties The Countess of Headfort, Butterianum, Lady Olive Guinness, and Madame Chasson were prominent.

It is difficult, however, to pronounce on the best of a collection which has been selected with so much care and judgment, every one having been chosen for some individual merit. Many besides those mentioned would prove ornamental additions to any garden; and as these shrubs may be moved with the greatest ease and safety (which their rapid growth frequently necessitates to prevent overcrowding), they may be truly called the most valuable evergreens we have. Most of those at Grassendale Priory have been moved at almost every season of the year, even in full flower, without deteriorating in any way; in fact one of the largest, a handsome white about 15 feet through and the same in height, was moved in flower two or three years ago, and made more growth the succeeding summer than it had ever done previously.

A standard Lady Godiva had over three hundred flowers fully out at the same time. It was placed in the position it now occupies last year, and is an excellent proof of the way Rhododendrons will succeed if carefully moved.—R. E. H.

DESTROYING THE ONION MAGGOT.—If your correspondent, W. Jones, will cover his Onion ground half an inch deep with coal ashes sifted through a half-inch sieve, and water at once with

liquid manure, and continue the watering once or twice every week unless the season is very wet indeed, I believe he will soon destroy the maggot.—D. WALKER, *The Gardens, Dunorlan.*

TWO KENTISH SHOWS.

DARTFORD.

THE annual Exhibition of the Dartford and District Horticultural Society was held on Wednesday, the 14th inst., in the grounds of Cranford Lodge, for which privilege the Society is indebted to C. T. Laurence, Esq. The entries were numerous, and the general quality of the exhibits was admirable, the plants being particularly noticeable for their freshness and vigour. Two tents were occupied with the gardeners' productions, one containing the plants, and the other the vegetables, fruit and cut flowers, while a third was devoted to the cottagers' classes. The arrangements were very satisfactory, and the whole conduct of the Exhibition was creditable to Mr. W. Etherington, the Secretary, and several energetic members of the Committee who ably assisted him.

Plants were well represented, several fair collections of stove and greenhouse plants being staged. Coleuses and the varieties of Begonias with fine foliage were also shown in excellent condition; the latter were exceptionally vigorous, and the former well coloured. Two fine collections of Cockscombs were exhibited, as dwarf as could be desired, with large richly coloured heads of flowers. Flowering Begonias were bright and effective. Several tasteful groups, Fuchsias, Ferns, fine-foliage plants, and numerous other plants contributed greatly to the pleasing effect of the tent. The chief prizewinners in the above classes were the following:—J. Honychurch, Esq. (gardener, Mr. Paris), A. H. Keep, Esq. (Mr. Bailey), R. White, Esq. (Mr. Collins), R. S. Dunbar, Esq. (Mr. Armstrong), R. C. Miller, Esq. (Mr. Hazell), E. A. Quail, Esq. (Mr. Manser), Mr. Preddy, and Mr. Ryder.

Fruit was not shown very abundantly, but collections of well-ripened Grapes, Peaches, Strawberries, &c., were staged by R. Stewart, Esq. (Mr. Etherington), J. C. Hayward, Esq. (Mr. J. Dean), and Messrs. Armstrong, Ryder, Collins, Hazell, and Manser, who were awarded the most important prizes in the classes. Vegetables were in excellent condition, the competition being very close, and the collections well made up. Potatoes were represented by several clean even examples. The successful exhibitors in these classes were J. B. White, Esq. (Mr. Westcrook), and Messrs. Etherington, Dean, Preddy, Paris, and Bailey. Some of the best cut flowers and Roses were staged by Messrs. Etherington, Westcrook, and Collins, the Roses being rather deficient in substance, but fresh and of good colour. The cottagers' exhibits were very numerous, and generally of exceptionally good quality. Vegetables, and particularly Potatoes, were remarkably fine, the latter even excelling those from the gardeners. Flowers, plants, and fruit were also very well shown.

The weather proved favourable, and numerous visitors attended the Exhibition; but the Society scarcely receives the support it deserves, although by judicious management the Secretary was able to obtain a small balance to the credit of the Society last year.

BEXLEY HEATH.

This Society held its fourteenth annual Exhibition on the same date as the above, and though it could not have been favoured with a more beautiful situation than Danson Park (the seat of A. W. Bean, Esq.), nor fairer weather, yet the exhibits were not very numerous, nor was the competition very keen in any of the classes. Several tents were, however, occupied with the contributions of gardeners and cottagers, the groups of plants filling the greatest portion of the space, and constituting the chief attraction. The tents were placed in a part of the Park which slopes down to an extensive lake, the ground rising beyond being densely and picturesquely wooded. The scenery was charming, and was evidently as much appreciated by the majority of the visitors as the Exhibition itself.

One of the chief groups of plants was that from A. W. Bean, Esq. (Mr. G. Taylor), which occupied the centre of a large tent, and contained some handsome specimens, a Croton variegatus being especially noteworthy for the rich colour of the foliage and vigour of the plant. C. A. Ionides, Esq. (Mr. Tomlin), also contributed a large and elegant group, comprising good Ferns, Dracanas, and Cockscombs. Both these groups were not for competition, being generously staged for the benefit of the Society. Mr. R. Smith, East Wickham, won the chief prize for a collection of Pelargoniums with well-flowered plants, a group comprising numerous varieties being also staged by the same exhibitor. The principal prizewinner in the classes for Fuchsias, Ferns, and many other plants was Mrs. Arbuthnot, Bridgen Place (Mr. Mitchell), who was awarded a large number of premier prizes for healthy well-grown plants. W. C. Pickersgill, Esq., Blendon Hall (Mr. Moore), sent a large group of plants not for competition, among them being a fine specimen of Dendrobium Farmeri with two large racemes of flowers. Cut Roses were bright and of fair quality, the chief exhibitors being the Rev. J. M. Fuller, Bexley; Mr. J. W. Todman, Chatham; the Rev. H. Johnson; and Messrs. Williams and Robins.

Fruit was well shown by Mr. Mitchell and T. Friend, Esq. (Mr. Wilcox), the latter, in addition to various collections and single dishes, staging several healthy well-fruited Peach trees in pots. Vegetables were fresh and good, those from J. G. Batehelor, Esq. (Mr. Foster), C. Graham, Esq. (Mr. Sewell), and Mr. Mitchell securing

the chief awards. The cottagers' productions were abundant and of good quality.

STENACTIS SPECIOSA.

MANY hardy herbaceous plants have recently been recommended as worthy of cultivation, and it is a little singular that the one

under notice has been apparently overlooked. It is a good old border plant, free and distinct, and once established needs little attention. We recently found it flowering in good condition in the kitchen garden at Southill Park, Bedfordshire, the seat of Samuel Whitbread, Esq., M.P., and were informed by the excellent gardener (Mr. Landers) that it is much esteemed for vase

Fig. 16.—STENACTIS SPECIOSA.

decoration. It grows freely in any ordinary garden soil. The colour of the flowers is bluish purple, and the height of the plant about 3 feet. It is readily increased by division, also by seeds, which if sown early produce flowering plants the same year. The engraving represents a spray from the plant above referred to.

GARDENS ON ST. SWITHIN'S DAY.

GARDENS begin to look sad and sodden. Most seeds have germinated fairly. A little more sunshine, a little less rain, and

a higher temperature than we have enjoyed in June for two or three seasons have done much to encourage Nature. The fields are now full of promise without, and beds and borders looked clean and hopeful. Small fruits were never more abundant. Strawberries are profuse and well flavoured. Caterpillars are committing terrible havoc amongst the Gooseberries and Currant trees, and the greater part of the extraordinarily luxuriant crops cannot come to perfection in some places from loss of leaves. Plums are a variable crop; Apples also; Pears generally a failure; also Apricots and Peaches. The rainfall of the last two days has been

disastrous, accompanied as it has been with almost continuous though distant thunder, and a most depressing thick atmosphere. The Rose blooms are ruined, and the trees are already making too much wood. In my small collection many, however, have yet to bloom, and only here and there have any of the new, planted last autumn, put in an appearance.—A. M. B., *Mid-Lincoln*.

THE HOLLYHOCK.

Of all the flowers of autumn none are more stately than the Hollyhock; and from a decorative point of view, no less than that of the florist, it has been missed from many a garden during the last few years. Everybody who has cultivated the Hollyhock knows the fungoid disease which attacks it and shrivels up leaf and stem, and it is one of those diseases which seem to have baffled all ingenuity. I have heard of three instances where it has been said to have been successfully combatted, but am afraid that the success was somewhat doubtful. Having bought a small collection of named varieties this spring, which were stated to be perfectly clean, but the disease was very soon apparent. They were planted in the best ground in the garden, and I have been trying to keep down the fungus ever since. This is how I have managed: If any leaf has shown the disease very badly it has been taken off, but on those leaves where only a few fungoid spots have been found the portion affected has been removed and immediately burnt. So far the plants have thriven, and are as clean as can be expected.

Owing no doubt to many of the lower leaves having been removed, a more than ordinary number of shoots are growing out from near the base of the plants. These will be taken off with a portion of the main stem attached and struck. Hollyhock cuttings strike very well in a northern border out of doors at this season, but I will give them the benefit of a cold frame, where the process is quicker. Later on, should the spikes prove weakly, I shall cut up the stems into pieces like Grape Vine cuttings, only keeping the leaf which belongs to the lead intact if possible. These strike root readily inserted in light soil and covered with a frame. When they are fairly struck they will be potted into 4-inch pots and wintered in a cold structure. The old stools by autumn will have grown. These will be lifted and placed in pots of a suitable size, and in a cold house will commence moving in February. By the end of that month the young growths will be grafted on pieces of roots and potted into 3 or 4-inch pots and plunged in a mild hotbed, being placed in the ground by the beginning of April.

I would advise those in the same position with regard to plants to try some such means as indicated above to raise a stock of healthy plants free from disease.—R. P. BROTHERSTON.

HERBACEOUS PLANTS AND BEDDING-OUT.

WE rarely meet one who is thoroughly satisfied with his gardens or flowers, otherwise there would be no occasion to change—no need for projected variety next year; no need for fashion in gardening, a subject on which I recently read a very interesting article from "WYLD SAVAGE." The fashion in gardening is at present changing from bedding-out, carpet bedding, and sub-tropical gardening to herbaceous gardening, but the persistent admirers of bedding plants have the almost certain consolation that a change will occur again. In a humble way I am an earnest grower of border and herbaceous plants. I have twenty beds and several borders more or less filled and more or less gay during ten months out of twelve. I am certainly not prepared to spend £100 a year on them like "WYLD SAVAGE." Like thousands of your readers my flowers only receive my attention after business hours, and a passing look in the morning. And this induces me to remark that I believe such people return to their garden and garden favourites with much greater zest than those who are masters of their own time, and can spend the whole day in their gardens if so inclined. I am, however, fortunate in having an unlimited supply of manure, many kinds of soil, and the general garden requisites, and do not come short of willing assistance; but allowing any second person to dig or hoe at random would mean death to some of my special favourites. I have heard some ladies and gentlemen complain that they find much difficulty in inducing gardeners to take an interest in herbaceous plants which they consider weedy and fugacious.

To secure a reasonable success in the culture of herbaceous plants time and patience are indispensable, besides a taste for collecting good old plants and industry and intelligence in propagating them, and even all this will be insufficient without constant care and supervision. A man who may make a great display with bedding plants in summer may not succeed at all with

herbaceous plants. The success I refer to is to have your beds always full; to have a young stock from seed, division, cuttings, &c., to take the place of the old; and without being too particular about effect to secure it wherever you can, always studying time and place, with height, colour, and duration of the flowers. This has only to be done once a year for Pelargoniums and other bedding plants; it is a constant study when a number of beds have to be always filled and always gay with annuals or perennials.

I will now briefly say generally how my beds and borders are occupied. The borders are edged with Box because it is clean, easily regulated, and trimmed, and always looks neat, but it has the disadvantage of harbouring slugs and answering as a sure refuge for weeds that are not easily eradicated. The front line is occupied with six varieties of Daisies, which have flowered freely for the past three months, and will shortly be divided and replanted. Immediately behind and designedly intended to overshadow them is a continuous line of *Viola Magnificens*, deep purple and very effective. This will extend ultimately to the Box, and cover the space occupied with Crocuses, Narcissus, and *Anemone coronaria* in variety, which gave a glorious mass of brilliant bloom since March last. Those spring bulbs I do not intend to move this year, but shall mulch or top-dress when cutting-in the *Viola* in autumn with leaf soil and comminuted hotbed manure. The next lines on both sides are a fine display of *Campanula Medium calycanthema* in various colours, and forming perfect pyramids, a mass of bloom about, and 20 inches high. I have thinned out the superfluous shoots, and this makes the plants much finer. Next year I purpose having a line of *Campanula persicifolia alba fl.-pl.*, which is perhaps at this season one of the best bouquet hardy white flowers, being symmetrically shaped, as double as a white Camellia, and lasting long in beauty. I have it flowering now finely in an inside bed. Behind the Campanulas are various plants designed to take their place when their bloom begins to fail, such as Dahlias and Gladiolus in variety, the spaces between the plants being occupied with *Mimulus* in variety, which I do not consider sufficiently appreciated, as I know few hardy flowers so brilliant or produced in such profusion. Double striped and crimson *Potentillas* are good, as also are double dwarf scarlet *Tropæolums*, a plant not so common as it ought to be; striped *Petunia*, *Myosotis dissitiflora*, *Alonsoa grandiflora*, *Convolvulus tricolor elegans*, Dwarf Alpine Phlox, *Linum flavum* and *L. sibiricum*, with dwarf Roses on their own roots. These are all low-growing, hardy, and look out finely from between and form a base covering for the Roses, Dahlias, and Gladiolus, and have their flowers partially and judiciously shaded by the Campanulas. Immediately at the back is a continuous line of selected *Polyanthuses*, which are of great value in spring. I have thus tried to notice what has been in those borders, what is in them at present, and, except to include bulbs, what I hope to have there in winter and spring.

I have little space to notice the bed occupants, but a few lines will enable me to note what is already blooming or preparing so to do. All the hardier varieties of Tuberous Begonias I have are bedded out, and even some of the caulescent forms which I found had green fly in the young curled leaves. The change has quite restored them, and the hint may be useful to some of your readers who may be coddling those plants inside. I have propagated a number of varieties of Fuchsias; a bed of them now forming their flower buds I expect to be one of the finest I shall have. Also flowering are Rose Campions, striped *Antirrhinums*, Pinks, Sweet Williams in variety, *Aquilegia cærulea*, *A. glandulosa*, and *A. chrysantha*, Verbenas, Stocks, Pæonies, Lilliums in variety, perennial Lupins, single and double scarlet *Lychnis*, *Pentstemons* in various colours, *Ranunculus* of sorts, Alpine Veronicas; and to this I may shortly add a special favourite, *Dianthus Heddewigii* Eastern Queen and Crimson Belle, Asters, Seabious, blue Salvias, Portulacas, and Irises, which from their great beauty I wish were less limited. Others with greater means will have rarer and better plants.—W. J. M., *Clonmel*.

[The flowers of *Campanula persicifolia alba* you have sent are very double, pure, and beautiful.—EDS.]

THE TEACHINGS OF NATURE IN GARDENING.

It is a common, and I fear too often a just, complaint against flower shows, that they induce our gardeners to give all their time to the growing of grand specimens for exhibition, to the neglect of what we may call landscape or picturesque gardening. This should not, and I think need not, be the case. We are undoubtedly indebted greatly to flower shows, not only for a great improvement in many florists' flowers, but also for bringing together true lovers of flowers to their mutual benefit. The two pursuits have separate ends, but may well be followed together to the advantage of each. For producing effect, no matter how

large or how small our plot of ground may be, let us aim high, and not be content with perpetual strivings to have our garden as gay as our neighbours'. Go at once to the fountain head—to Nature herself; let us study hedgerow banks and shady lanes a little more, to see for ourselves what it is that produces such lovely effects. We should, I fancy, derive more enjoyment from our gardens, and with half the expense and trouble.

As an instance of Nature's teaching in my own experience I may mention that some years ago I made what we call a Swiss bed upon the lawn—i.e., an oblong flower bed raised in three terraces, one above the other, kept in shape by larch poles split in half, the rough bark outside. When finished, the bottom terrace was planted with an edging of *Cerastium* and the orthodox *Pelargoniums* and *Calceolarias* behind. The second row had an edging of *Lobelia* and a smaller *Pelargonium*; the highest bed had *Fuchsias* alone. The whole effect I believe was fashionable but never picturesque, as may be judged from the fact that one individual compared it to a coffin. Other disappointments followed: the *Fuchsias* could not be kept moist enough to thrive, and the *Lobelias* refused to hide the wood of the second terrace.

In autumn white *Arabis*, with bulbs and other spring flowers were planted, and a few Ferns set on the shady side, and partly from illness, and partly from no longer taking pleasure in the structure, it was entirely neglected, and Nature succeeded where Art had failed. For many years now no part of my garden gives more pleasure than this bed. The Ferns took entire possession of all the shady side, seedlings springing up all over the woodwork. On the sunny side the white *Arabis* has covered the whole from top to bottom, not leaving a scrap of wood or soil to be seen, making for two or three months a snowy mound, and the rest of the year a pretty grey background in which can be placed any number of plants in pots, the pots being completely hidden.—C. A. K.

WE are gratified to be able to announce that the Council of the Royal Horticultural Society have awarded the large gold Flora medal to MR. JOHN DOMINY in recognition of the distinguished services he has rendered to horticulture generally, and especially for the remarkable results he has achieved in hybridisation. This honour is well merited, and it could not have been conferred at a more opportune time, when Mr. Dominy is reported to be about to retire into private life.

— LAST year was most unfavourable for CARNATIONS AND PICOTEES. The flowering of the plants was of unparalleled lateness, and thousands of layers failed to root. Florists sustained great losses during the winter, and had to commence the present season with much weaker plants than usual or old stools. This was the case with the senior Honorary Secretary of the southern section of the National Society established for encouraging the cultivation of those flowers and the production of new varieties. Mr. Dodwell's losses amounted to three thousand plants, and it would not have been surprising if the display at Larkhall Rise, Clapham, had this year been only moderate both as regards extent and quality. By some means, however, the skill and energy of the veteran cultivator appears to have surmounted all difficulties, for he has nearly or quite a thousand pots of clean healthy plants, most of which are producing splendid flowers. These not only embrace the best named varieties in cultivation, but a great number of seedlings, not a few of which are of remarkable purity and brilliancy of colour. Many grand seedlings are now in full beauty, and will have passed their best before the Show, notably some magnificent scarlet and crimson bizzars and pink and purple flakes. This is unfortunate, but many others of high quality will probably not have lost their freshness by the date named, and there is good prospect of a fine exhibition, in which midland growers will have a favourable chance of successfully competing. The Exhibition will be held in the

Royal Horticultural Society's Gardens at South Kensington on the 27th inst., and will be worthy of the patronage of all admirers of these chaste, beautiful, and sweet hardy flowers.

— WE continue to hear of instances of the POTATO DISEASE occurring in various districts. The heavy rains accompanied with a rather high temperature have been favourable to the spread of the murrain, and if the storms continue the result can scarcely fail to be disastrous in many fields and gardens. Early varieties that have produced tubers of a good size should be taken up at once, even if the haulm is comparatively green. The tubers if spread thinly in an open shed will mature and soon be ready for storing; if it is not convenient to take them up the tops should be pulled up—not cut off as is so often recommended—and the Potatoes, although they will not increase in size, will mature in the ground. But the work must be done immediately the first specks of the disease are seen on the foliage or stems; a day's delay may render such work quite fruitless. Occasionally a few plants may be seen affected amongst the later varieties, the great bulk being untouched. The importance of promptly removing the tops thus affected cannot be too strongly urged, as it is the only means within the power of the cultivator of checking the spread of the destructive murrain.

— WE have received from Mr. H. Cannell of Swanley a box of PETUNIA FLOWERS GROWN UNDER GLASS, which are remarkable alike by their size, richness, and variety of colours. Many of the single flowers are 5 inches in diameter and of great substance, the colours represented ranging from pure white with faint purple bars to rich reddish purple and glowing magenta selfs. Some of the flowers are fringed and others smooth. Many smaller flowers of excellent form are not less beautiful, some of them being distinctly barred and others chastely reticulated. Even more striking are the double forms, some being purple heavily fringed, almost tasselled, with pure white; some being white in the centre with purple-margined white outer petals; some plum colour faintly margined with white; others purple, heavily margined; some blotched, some striped, and all beautiful. We have never seen finer flowers than these, and they represent a strain of undoubted excellence.

— WE are informed that preparation is being made for holding a great FLOWER SHOW AT THE ALEXANDRA PALACE on August 7th, at which bouquets and table decorations will form an important feature. Particulars of the Exhibition will no doubt be duly advertised.

— IN consequence of the unfortunate weather that prevailed during the LEEDS HORTICULTURAL SHOW, and the great loss thereby incurred by the Society, arrangements have been made for holding a supplementary Show to open on August 2nd. Such efforts of the Committee to retrieve their loss deserve the support that the inhabitants of the populous districts are sure to give if the weather permits them. A liberal schedule is issued, and we observe that two prizes of 2 guineas each are offered in an open class for one ball and one bridal bouquet.

— A CORRESPONDENT states that "A house has recently been erected for ZONAL PELARGONIUMS AT CLOVERLEY HALL GARDENS. It is a span-roofed structure with a bed in the centre and at each side, with a walk all round. The house is full of plants in 6 and 7-inch pots and in excellent condition; the trusses of bloom are of immense size and the colours bright. The collection comprises new varieties of recent introduction as well as old varieties of sterling merit. No plants are more worthy of a good house devoted to their cultivation either for summer or winter blooming. They are easy to manage and never troubled with insects. Mr. Jones is a successful cultivator of *Pelargoniums*."

— "W. B." writes that "The NEPENTHES AT HAWKSTONE GARDENS, SALOP, are most vigorous, the foliage luxuriant and fine, and the numerous pitchers are of an immense size. Mr. Pratt is very successful in growing and propagating Nepenthes. In the conservatory is a fine specimen of *Bougainvillea spectabilis*. In its present position the plant flower as freely as *B. glabra*, and the colour is much darker.

— A CORRESPONDENT desires to know the weight of the HEAVIEST PINE APPLE that has been grown in this country, with the name of the grower and the variety. We remember Mr. Fleming of Trentham exhibiting in the Regent Street rooms of the Horticultural Society a fruit of Providence weighing 14 lbs., and one of the Ripley Queen 7 lbs. 10 ozs. He afterwards cut a fruit of the Queen weighing 8 lbs. 11 ozs. We do not name them as the heaviest fruits recorded, but they are worthy of mention, and we shall be glad if any of our readers can give particulars of heavier fruits. As an instance of successful Pine culture it is recorded that a Mr. Baldwin, who was gardener to the Marquis of Hertford at Bagley, cut thirty-six fruits of Providence in 1822, which weighed 280 lbs. 4 ozs., the largest fruit being 11 lbs. 8 ozs. Mr. Bailey of Shardeloes has, we believe, also grown fruit of about the same weight.

— AT the late Wimbledon Show (a report of which, owing to the extreme pressure on our columns, we were unable to insert last week) there was, we are informed, a falling-off in the specimen plant classes. Ferns were good, Messrs. Nunns, Bridger, and Bentley securing the prizes. Zonal Pelargoniums were numerous, those from Mr. G. Legg, Worple Nursery, being of marked excellence. Table plants, which the Wimbledon gardeners grow so well, were as usual in fine condition, the prizes being secured by Messrs. Bridger, Bentley, Callard, and Law. Roses were an attractive feature, Messrs. Moorman, Gibson, Starr, Curtis, Dr. Booklees (who won the silver cup for amateurs), Coleby, Dixey, and Brown being the successful exhibitors. Lady Peck's prizes for cut blooms of herbaceous plants brought out good competition, Messrs. Fanning, Boylett, and Bridger being the successful exhibitors. Vegetables were superior, and wild flowers from Messrs. Ogden and Appleby pretty. The Exhibition was held in Mr. Schlusser's beautiful grounds at Belvidere House, and was well managed by Messrs. Appleby, Jordan, and Lyne.

— A RARE and very charming Orchid is now flowering in Mr. B. S. Williams' nursery at Holloway—*ANGRÆCUM SCOTTIANUM*. This species is quite distinct from all others, the leaves being narrow, not greatly exceeding an eighth of an inch in diameter, very stout, gracefully arched and channelled. The flowers are white, singularly pure and glossy; the lip being a little more than an inch in diameter, admirably formed and shell-like, the tail-like appendage being nearly 4 inches in length, slender and waxy. By its texture, purity, and elegance this species is a beautiful and noteworthy form of a diverse and remarkable genus of Orchids. It is a native of the Comoro Islands.

— AMONGST other Orchids flowering in the same establishment *CATTLEYAS GIGAS*, *VIRGINALIS*, AND *SUPERBA* demand notice. *C. gigas* is a magnificent variety, the colours being gorgeous and the flowers large. *C. virginalis* is a chaste white flower with a yellow lip, and remarkable for its powerful aromatic perfume. *C. superba*, a difficult plant to grow, is in superb condition, one spike having five richly coloured, smoothly massive flowers that command the admiration of all visitors. *Sobralia macrantha* is also fine; *Masdevallia atro-purpurea*, intensely rich; *Oncidium prismatocarpum*, powerfully Hawthorn-scented; *O. dasytyle*, curious by its creamy lip and nearly black bee-like centre; *Coclogyne Massoniana*, very distinct by its pale buff sepals and chest-

nut brown lip; *Thunias Dodgsonii* and *alba* in excellent condition. The fine collection of plants not flowering—*Vandas*, *Cattleyas*, *Odontogloss*, and others—merit a word of recognition by their manifest health and cleanliness.

— SUSPENDED from the roof of one of the houses NEPENTHES attract attention by their great profusion of fine pitchers. Nearly all the best forms are represented, including the striking new *N. Outramii*. We never saw *N. Hookerii* finer than it is here; indeed, all the plants, which are not large, are remarkable for the great number, freshness, and colour of the pitchers. Fine as are the new Nepenthes now being distributed from the Victoria Nursery, there are others "on the way" that will prove worthy companions to them, and of which more will be heard in due time.

— MESSRS. DANIELS BROS., of Norwich, have sent us flowers of their NEW GIANT VIRGINIAN STOCK. The variety is very distinct and extremely attractive, the colour being very deep rosy purple; it is much the darkest variety that has come under our notice, and is a welcome addition to the other forms of this pretty annual.

— THE *Irish Farmers' Gazette* states that *DISA GRANDIFLORA* was one of the most noteworthy, as also one of the most attractive, plants at the Royal Horticultural Society's Show recently held in Dublin, and exhibited by the Rev. Frederick Tymons. Larger and finer specimens have come under our notice, but we do not remember seeing at a public exhibition so well furnished, well flowered, and symmetrical a specimen as that now alluded to, which had twelve spikes with an average of four highly coloured blooms each.

— ON the 13th and 14th inst. Mr. J. C. Stevens sold the COLLECTION OF ORCHIDS that Mr. Philbrick, Q.C., Avenue Road, Regent's Park, has been some years in obtaining. The following were the principal prices realised:—*Anguloa Ruckerii sanguinea*, 14 guineas; *Odontoglossum vexillarium*, 4½ guineas; *Dendrobium Wardianum*, 9 guineas; *Masdevallia Backhouseana*, £6 10s.; *Angræcum sesquipedale*, 19 guineas and 10½ guineas; *Aërides Lobbii*, 7½ guineas; *Aërides Schroderi*, 24 guineas; *Saccolabium Holfordii*, 19 guineas; *Saccolabium Blumei majus*, 11½ guineas; *Cattleya dolosa*, 11 guineas; *Lælia anceps*, 9 guineas; *Cattleya Trianae rubra*, 15 guineas; *Lælia anceps alba*, 14 guineas; *Sophrontitis grandiflora*, 10 guineas; *Cattleya labiata*, 5½ guineas; *Lælia elegans Turneri*, 10 guineas; *Lælia Wolstenholmei*, 14 guineas; *Cattleya gigas*, £6 10s.; and *Angræcum sesquipedale*, £6 10s. The total amount realised by the sale was £1075 19s.

— MR. FREDK. DURRANT succeeds Mr. Webber as gardener to Ambrose Isted, Esq., Ecton House, Northampton; Mr. J. WRIGHT succeeds Mr. Durrant as gardener to J. E. Cooke, Esq., Knowle Hill, Cobham, Surrey; and Mr. W. GURMAN, late of Springfield, Great Marlow, has been appointed gardener to R. Burrell, Esq., Fairthorne Park, Botley.

AQUILEGIA SKINNERI.

THE Columbines are deservedly admired by all growers of hardy plants, and the increase in the number of distinct and handsome forms within recent years now permits the acquirement of a large and diverse collection. The admirable results that have attended the efforts of some hybridisers are well known, and the numerous intermediate forms thus produced in some instances excel their parents in attractiveness. This is due to the peculiarly variable character of the *Aquilegia*, considerable diversity of colouring being easily induced by judicious crossing, and doubtlessly much more will yet be done in that direction by observant and persevering growers. One valuable quality of the Columbines is the readiness with which the majority can be increased either by seed or division of the plants, and their hardiness in many districts and their elegant habit of growth recommend them as desirable additions to the herbaceous borders.

One of the most beautiful species of the genus is *Aquilegia Skinneri*, which is represented in the accompanying engraving (fig. 17). This plant is a native of Guatemala, whence it was sent to this country about forty years ago by G. U. Skinner, Esq., after whom it is named. The first plants were received at Woburn Gardens, and there flowered for the first time in England. It was then

treated as a stove plant, being regarded as too tender to endure this northern climate without protection; but the weakly unsatisfactory plants obtained under that culture soon induced the adoption of a more suitable course of treatment, and it was found that the plant only displayed its real beauty in the border. Such is the position now usually accorded it, and if the soil be moderately

Fig. 17.—*AQUILEGIA SKINNERI*.

rich and well-drained, and the border somewhat sheltered and warm, the best results will be obtained.

The form of the flowers is well shown in the engraving, but the colour is the most striking quality, the sepals being green, and the long spur-like petals of a rich red tint, fading to an orange shade near the upper portion. The stamens are greatly protruded and they are terminated by large bright yellow anthers, the filaments being of a greenish tint. The stems of the plant are purplish,

and the elegantly divided leaves of a deep rich glossy green. It flowers during the present month.—R.

PEAS AND BEANS IN SUCCESSION.—We are now gathering Peas and Broad Beans from rows from which we have been gathering for more than five weeks. As soon as the first few blooms were open the plants were topped, which caused lateral growths

to issue from bottom to top of each stem, and these are now blooming and fruiting most abundantly—in fact the crop is much larger than that from the first main stems. Those wishing to save seed from any new or good variety of Pea or Bean should adopt this plan, as in good soil it more than doubles the produce.—
A KITCHEN GARDENER.

LA DUCHESSE DE MORNY ROSE.

I SHALL be glad to have the opinions of rosarians upon the following point—whether the above Rose should be shown as a light Hybrid Perpetual and gain honours against such light Roses as La France. Some comment evidently took place at the National Rose Society's Show, held in Manchester on the 17th, when La Duchesse de Morny was placed before La France. Some contended that this should not have been so, and that the Rose in question was not a light Rose. I ask, Can a Rose that answers to the description of "bright but delicate rose colour, the reverse of the petals silvery," be called a dark Rose? If so we might as well say Alfred Colomb and Marie Baumann cannot be called dark where such varieties as Duke of Edinburgh and Charles Lefebvre come. If I understand the schedule rightly Hybrid Perpetuals are divided only into light and dark, and no more minute distinction made. Under such conditions I think Mr. Jowitt is justified in exhibiting La Duchesse de Morny as a light Rose.—A LANCASHIRE GROWER.

ROYAL HORTICULTURAL SOCIETY.

THE following is an epitome of the lecture delivered on the plants exhibited at the last Meeting by the Rev. G. Henslow, Secretary to the Scientific Committee, and for which we had not space in our last issue. The first group of plants to which attention was drawn was a fine series of *Iris Kämpferi* from Japan, exhibited by Messrs. Veitch. The lecturer explained how the process of becoming "double" was carried out—first by the three inner petals, usually small, being much enlarged, an extra number of stamens appearing as small petals, and the style becoming more petaloid, so that probably by continued cultivation flowers resembling *Pæonies*, only purple, might be expected to be produced. The lecturer described the fertilisation by insects of the *Iris* and *Crocus*.

The chief display was made by *Begonias*, consisting of variations from hybrids between *B. boliviensis* and *B. Veitchii* and other species. Allusion was made to the tendency to change the sex; the stamens especially putting on stigmas, while one specimen exhibited showed the pistil surrounded by stamens. The stems of some species contain probably potassium oxalate, and are used like *Rhubarb*, and may also be employed like salts of lemon for extracting ink, though the juice is liable to leave a red stain instead.

A beautiful species of *Utricularia* and another of *Nepenthes* furnished materials for a short digression on the habits of the carnivorous species of those genera.

With regard to *Orchids*, a remarkable species of *Nanodes*—viz., *N. Meduse*, was exhibited by Sir T. Lawrence; *N. discolor* is another very small species about 1 to 2 inches high. A fine *Phalaenopsis* furnished an illustration of the fertilisation by insects, the candle of the pollinia undergoing a remarkable curving process, while at the same time they are depressed; the object being apparently to shorten the distance between the disk and pollen so as to hit the stigma more accurately and effectively.

Gloxinias furnished an illustration of reversion; for it is presumable that all irregular flowers were in their ancestral state regular, and horticulturists now endeavour to select those which assume an erect habit and regularly circular outline, in other words, which are reverting to the ancestral type.

Pelargoniums are remarkable for illustrating the fact that physiological differences are often more pronounced than morphological; for it is found that the forms with fine well-pronounced spots—i.e., one on each petal, will not cross with those possessing only two marked spots, the other three petals having none or faintly marked only. A similar refusal to cross resides in the Zonal *Pelargonium* and the smooth-leaved scarlet varieties.

SCHIZANTHUS AND LOBELIA ERINUS IN POTS.

IN a situation I held many years ago there was a conservatory which held about three hundred plants and had to be kept gay with flowers throughout the year. With the exception of some *Camellias* and a few others, all the plants were removed as soon as they had done flowering, and others coming into flower were brought from the vineries and a plant pit to take their places. Some plants commonly used as outdoor plants were grown in pots for this structure. None answered better or were more admired by my employers and their friends than the *Schizanthus*, which is a well-known annual, and *Lobelia Erinus* white and blue. Both were grown as annuals from seed sown in July, two or three plants being placed in a 4-inch pot as soon as they were large

enough. The plants were well exposed to light and air, were shifted into larger pots as they required it, and had good soil to grow in. About April they were finally potted into pots 11 inches in diameter. By May, when the *Schizanthus* plants began to flower, they were 3 feet or more in diameter and the same in height. When in full flower they were no mean ornaments for the conservatory and sitting-room, being pyramids of butterfly-like flowers. *Azaleas* and *Pelargoniums* flowering in the same house at the same time were not more admired than the *Schizanthus*. As the roots of the *Schizanthus* plants are brittle some care is necessary to keep the balls unbroken in shifting them into larger pots. In growing *Schizanthus* plants in pots the shoots should never be stopped by pinching their points off, and they seldom need training or tying. The varieties of *S. pinnatus* are the best for pot culture and show. *S. retusus* and its varieties I could never grow into fine plants.

Well-grown plants of *Lobelia Erinus gracilis*, blue and white, in flower are very charming. They come into flower about the end of May and last till August. With us they were treated like the *Schizanthus*, and grew into handsome specimens, measuring about 3 feet across; and by reason of their trailing habit of growth, their pots (11-inch) were quite hidden from view by foliage and flower. Two or three of such plants were grown annually, one-third of them blue, one-third white, and the other third blue and white together. The lady of the family I served liked the white plants very much, and had every year two of them in her sitting-room. By uplifting the tangled mass of shoots with her fingers she made her two plants look much larger and better than those in the conservatory; they were in shape somewhat like an umbrella fully expanded. *Lobelias* for pot culture should not be topped. *Lobelia speciosa* and some others are not well adapted for culture in pots, their growth not being sufficiently slender and pendulous.—A. PETTIGREW.

NOTES AROUND MANCHESTER.—No. 2.

DIDSBURY, a village three or four miles south of Manchester, is one of the most healthful and pleasant suburbs of that city, being situated in an open district comparatively free from the poison-vomiting factory chimneys which are so abundant in neighbouring and less-favoured localities. In consequence of this immunity from one of the greatest enemies to vegetation—viz., smoke, the plants and shrubs of all kinds have some chance of thriving and rewarding their cultivators for the care bestowed upon them. Residents have not been slow to take advantage of these opportunities, and all the numerous villas in the neighbourhood have gardens, varying in size and importance, but equally indicating by their neat fresh appearance the attention they receive. The majority merely contain lawns, shrubberies, and flower borders in the typical and somewhat formal style so prevalent in gardens of that character round London and large towns generally; but there are some occupied by gentlemen who have acquired collections of plants of considerable value and extent, and one of the most remarkable of these establishments I will now briefly describe.

BROCKHURST.

It is very doubtful if a better example could be found of the admirable effects that can be produced in gardens of moderate extent by the exercise of artistic ingenuity and care in their design and arrangement than is shown in the one under notice. Although by no means specially favoured in regard to position, except that the garden slopes down to the valley of the Mersey, yet it has been rendered both highly attractive and interesting. Mr. W. Brockbank, the genial proprietor, is a gentleman who has devoted much time and care to the formation of a collection of alpine and herbaceous plants, florists' flowers, &c., and he now possesses nearly eight hundred distinct forms, exclusive of a large number of *Auriculas*. Some of these are grown in houses and frames, but the majority are planted on the rockery, which forms the chief feature of the garden. Not content with the conventional heap of stones that passes for a rockery, Mr. Brockbank has succeeded in producing something which, if only on a moderate scale, has the merit of possessing some pretensions to naturalness. What may be termed the framework is composed of huge blocks of Rochdale flagstone arranged to imitate the stratification of rocks, and, being upon the steep portion of the incline, they are disposed so that they appear to be the natural outcrop of a geological formation. Smaller pieces are employed to fill-up and form sheltered nooks and corners suited to the various requirements of the alpine treasures that are planted in them. Paths wind about at different levels—not obtrusive, broad, gravelled paths, but in judicious accordance with the general design, which altogether is admirable and worthy of adoption by all who can obtain the necessary materials.

In another and lower portion of the garden a marshy position is turned to good account as a home for the various beautiful and interesting plants that frequent such localities, and their healthy condition testifies to the accuracy with which their requirements have been studied. On the slopes overshadowed by trees are Ferns in abundance thriving admirably, much as they are seen growing wild in a shady and woodland nook. Thus Mr. Brockbank imitates Nature as far as practicable in his gardening, and how successfully can only be adequately judged by those who have had the pleasure of visiting his beautiful little establishment.

To enumerate all the plants of interest contained in this collection would far exceed the space at my disposal, consequently I must confine my remarks to the most noteworthy. Spring flowering plants are largely grown, for not only are they very beautiful, but the soil at Brockhurst being of a sandy nature, renders it unsuited to summer-flowering plants, as during the hot season it becomes excessively dry in exposed positions. Spring flowers, however, succeed capitally, Narcissi being particularly luxuriant. Of these there is a fine collection, including many species and varieties, among which the beautiful *Lcedsi* forms are well represented. *Narcissus Horsfieldi* is grown in numbers, and produces a fine display when at its best. Primulas, however, receive considerable attention, and constitute what Mr. Brockbank terms his *spécialité*, although, judging by the fine condition of the plants generally, that would equally apply to all. Primroses of all kinds are grown in the greenhouses, frames on the rockery, and in the borders. The majestic *P. japonica*, the charming little *P. rosea*, and scores of others contribute their attractions; such fine forms as *P. cortusoides*, *P. integrifolia*, *P. viscosa*, *P. denticulata*, *P. farinosa*, *P. scotica*, *P. Munroi*, *P. cashmeriana*, and *P. sikkimensis* being well represented. A great number of forms of *P. acaulis* are also grown, and some are extremely beautiful, the shades of colour varying from white to rich crimson, the blooms being of great size and good form. Auriculas and Polyanthuses are cultivated in quantity, the collection of varieties being especially fine. Among the latter are two rare forms that are greatly valued by florists—namely, Cox's Prince Regent and Maud's Beauty of England, which Mr. Brockbank prides himself upon possessing perfectly true. Many other plants are grown in the borders, bulbs, particularly Lilies, being very abundant.

On the rockery are hosts of charming plants, and some extremely rare. Very noticeable at the time of my visit were clumps of the beautiful *Saxifraga Wallacei*, which was flowering most profusely. Several other handsome species of the same genus were also remarkably fine, particularly *S. pyramidalis*, *S. nepalensis*, and *S. lantoskana*. Globeflowers made an attractive display, including all the best forms in cultivation, and the rare dwarf variety of *T. europæus* called *pumilus*. One especially interesting plant was the Edelweiss, *Gnaphalium Leontopodium*, which has flowered this season and attracted much attention when exhibited at the Manchester Show. Aquilegias were strongly represented, no less than twenty-two varieties being grown. Mr. Brockbank's mode of treating these handsome plants is worth noting, for it appears eminently successful. They are all raised from seed, large numbers of young plants being thus obtained to keep up the succession. The seed from the old plants is also allowed to fall on the soil, and the plants thus produced are pricked off wherever required, generally in moderately rich soil. The value of *Doronicums* for flowering in spring has been recently referred to in the Journal, and at Brockhurst their qualities were admirably exemplified.

The lower portion of the garden or the "woodery" has already been briefly noted, and I have only to add that terrestrial Orchids thrive there luxuriantly. *Cypripedium spectabile*, *C. parviflorum*, and *C. Calceolus* I have rarely seen in such fine condition. They were flowering profusely, apparently quite uninjured by the severity of the past winter, which had affected surrounding shrubs and trees very seriously.

In addition to rockery, woodery, lawns, flower borders, &c., what may be termed the glass portion of the establishment is also well worth notice. Several houses are devoted to plants of various kinds, Roses in pots receiving considerable attention. Vines are well grown, and were at the time I saw them giving promise of an excellent crop. One house has been converted into a "natural" fernery, where Ferns, Selaginellas, and other shade and moisture-loving plants grow vigorously, much taste having been displayed in the construction and arrangement. The houses, although not large, are fitted up with all the latest improvements in the way of heating and ventilation, and prove highly satisfactory to the owner, and creditable to Messrs. Richardson & Co. of Darlington, by whom the majority were erected.

Such is a brief and inadequate description of Brockhurst, which for its size could scarcely be surpassed in beauty and interest; and

in conclusion I may remark that not only does Mr. Brockbank grow his plants well, but he also exhibits them well, as was indicated at the Manchester Spring Show, when he took high positions both with hardy plants and Roses in pots. Although he personally superintends his garden to a great extent, yet he is ably assisted by his head gardener, Mr. Morris, who enters fully into his master's love of plants.

Since the above was written I have received a description of the garden from Mr. Rogers, the Secretary of the Manchester Botanists' Association, whose visit to Brockhurst was recently recorded in the Journal. Mr. Rogers very ably indicates the principal attractions of the garden, and furthermore states that the excursion proved very enjoyable, owing to the cordiality of the worthy proprietor.—L. CASTLE.

COWSLIP, PRIMROSE, AND OXLIP.

MANY years since the late Professor Henslow raised all the above forms from the same plant. Amongst a lot of seedling Polyanthuses I this year had a common Primrose. Coloured Cowslips not unfrequently occur in the marlstone coombes of this parish. I have lately stated that in one of the coombes a large patch of coloured Cowslips, some coloured like common Oxlips, occurred in the spring, and amongst them a decided crimson Primrose. The fine forms of Primrose raised by Colonel Clarke produce seed naturally here, and retain their original character.—SIBBERTOFT.

LECTURE ON THE PELARGONIUM.

BY SHIRLEY HIBBERD.

(Continued from page 14.)

THE Zonal race acquired importance subsequently to the large-flowering section. Those we collectively term "Zonals" were grouped by Sweet under the generic designation *Ciconium*, and the most important of this genus are *Ciconium zonale*, introduced in 1710, and *Ciconium inquinans*, introduced in 1714. These are the two parents of the race, no doubt, but their differences do not account for the fact that in the garden varieties we have every imaginable variation of leafage and of bloom. It is likely that *Ciconium reticulatum* of Sweet (143), a very distinct hybrid, gave the first touch to the variegation of the leaves, which has in recent years attained to such extraordinary development. In any case, this hybrid marks a distinct departure and appears well suited to be the founder of a race.

The "Nosegay" section is the oldest of the Zonals. The founder of this section is *Ciconium Fothergilli*, the figure of which by Sweet (226) would nearly serve to represent a good Nosegay of the present day, and it may therefore be concluded that the Nosegays have been less modified than the Zonals that represent *zonale* and *inquinans*.

Another early section is that with green leaves and pink flowers, of which we may consider Christine the modern type. This section is foreshadowed in *Ciconium cerinum*, which is admirably figured by Sweet (176). Here we have pubescent leaves and flowers of a soft rosy pink colour, the petals of which are beautifully rounded and nearly equal in size. Cultivators who remember *Lucia rosea* will have no difficulty in connecting the dwarf bedding Pelargoniums of the Christine class with this beautiful wax-flowered Pelargonium, which Sweet regarded as a true species.

The most famous of the Zonal section is the green-leaved scarlet bedder known as General Tom Thumb, a descendant of Frogmore Scarlet, and a competitor of Huntsman, Cooper's Scarlet, and many more that the General quickly vanquished from the field. This famous variety was raised by Mr. Willson, gardener to W. Pigott, Esq., of Dullingham House, Newmarket, about the year 1842. It is said that as a seedling it was condemned and handed over to some children to be tormented, and very soon found its way to a dust-bin. But by some accident it was dragged from the dust-bin and planted, and as the summer advanced it manifested its character, and secured its fame and many more admirers than Barnum's *protégé*. But many persons have some kind of claim to the honour of raising Tom Thumb, for there prevailed during some fifteen years—say from 1840 to 1855—a mania for raising scarlet Pelargoniums adapted for bedding; for those were the days of the horticultural scarlet fever, and many varieties nearly alike came forth from various quarters. Many of these passed for genuine Tom Thumbs, and many perhaps were quite as good. However, the original and true variety differed from most of the others in this respect, that it rarely ripened a seed unless it was artificially fertilised, when it was as prolific as any. This fact separates it far from Christine, which is an inveterate seeder. The leafage also puts them far asunder, for Tom has a smooth papery leaf of a yellowish green, and Christine has a thick soft leaf of a bluish green—one takes us back to *inquinans*, the other to *cerifera*, and Nature ordered the characters ages ago in the solitudes that stretch away drearily to the west of Cape Town.

The pink-flowered Christine was raised by Mr. F. R. Kinghorn of Richmond in the year 1852. The parents were Ingram's Princess Royal and an old pink Nosegay, which was formerly much used for training on walls and pillars. The peculiar softness and blue tone of

the leafage of Christine do not appear to be accounted for by the parentage, there being in it such evident traces of the *Cerinum* or *Monstrosum* of Sweet. Mr. Kinghorn, to whom I am indebted for its history, tells me that he very soon made note of its strong individuality, in which it seems to rise to the rank of a species, and reproduces itself freely and truly from seeds. During some fifteen years it was the most popular of all bedding plants, for it outran Tom Thumb at last. The beautiful Rose Queen, sent out in 1855, was one of the good things obtained by Mr. Kinghorn in the same batch with Christine. This has higher quality, but never proved so good a bedder, and therefore never attained to great popularity.

It would be unfair to omit all mention of the variegated-leaved varieties, because in a good bedding display they contribute features fully as important as the strong colours. They tone down and harmonise and divide. In the year 1844 there were very few variegated Zonals known, and only one with bright scarlet flowers; this was called Lee's Variegated, and was very scarce. It was, I think, raised by Mr. Bailey, then gardener at Nuneham Park. Mr. Kinghorn selected this Lee's Variegated to supply pollen for a cross on the old *Compactum*, which was the seed parent, and in the first batch of seedlings from this cross he obtained the celebrated *Cerise Unique*, and the much more celebrated Flower of the Day, the most useful and most famous of all known variegated-leaved Zonals. Mr. Kinghorn to this day considers this was the greatest advance ever accomplished at one bound in work of this kind, and I thoroughly agree with him. The large seedling plant and two smaller plants of Flower of the Day were purchased by Messrs. Lee in August, 1849, and in August, 1850, they had a stock of 1500 plants of various sizes to offer for sale—a wonderful sight in those days, and one worth seeing even now.

It so happens that the last-named, most useful of all the silver-leaved varieties, conducts us direct to the fountain head of the whole race of the tricolors. In the year 1850 Mr. Kinghorn raised from Flower of the Day the beautiful variety known as *Attraction*, the leaf of which has a silvery margin and a dark zone, diffusing subdued rays of red and rich brown outwards upon the creamy band that girdles it. The *Attraction* was the first silver tricolor, and one of the parents of the first golden tricolor. Mr. Grieve, in his admirable *History of Variegated Pelargoniums*, tells that he fertilised a dark-zoned variety known as *Cottage Maid* with the pollen of *Attraction*. Amongst the seedlings occurred one that was the parent of the dark-zoned Emperor of the French, from which came the whole race of golden tricolors. From *Cottage Maid* and *Golden Chain* (the latter being the pollen parent) Mr. Grieve obtained *Golden Tom Thumb*, and from Emperor of the French and *Golden Tom Thumb* (the latter being the pollen parent) he obtained *Golden Pheasant*, the first true golden tricolor. This same Emperor of the French, grandson of *Attraction*, produced by the pollen of *Golden Pheasant* the two most famous of the tricolors, Mrs. Pollock and *Sunset*.

The double Pelargoniums have had a career of fifty years at least. A handsome double purple, named *Veitchianum*, not of the zonal section, but allied to *Barringtoni*, was raised by the late Mr. J. Veitch at Exeter about the year 1828, and its portrait appears in Sweet's supplementary volume (81), where nearly next door to it is another double named *Implicatum* (86), which is as like the double *cucullatum* Mr. Cannell has been growing of late as can be expected of things that are probably different.

But the proper history of the doubles begins with Wilmore's Surprise, a handsome semi-double variety, which was described and figured in the *Gardeners' Chronicle* of August 17th, 1850. This was found by Mrs. Wilmore, of Strawberry Vale, Edgbaston, growing in the midst of a plantation of Hollyhocks, and so unaccustomed were the eyes of the florists to such a thing that it was considered to be a true hybrid between a Pelargonium and a Hollyhock. A remarkable fact in the history of this variety is that simultaneously with the finding of it in the garden at Edgbaston it was obtained by the late Mr. Beaton as a sport from *Diadematum rubescens*, and was by him named *Monstrosum*. The Edgbaston plant was shown by Messrs. Lee, of Hammersmith, at Regent's Park on the 30th of June, 1852, and Mr. Beaton suppressed his *monstrosum* in favour of it.

The double Zonals are of later date, one of the earliest being the crimson-scarlet *Gloire de Nancy*, which was first shown in this country in the year 1866. In the year 1869 there were seventeen double Zonals brought into public notice, and of other sections in that year the collective name was *Legion*. At this point of the story the subject becomes too large to be handled on the present occasion. It is quite certain that during the few years when Geraniums were everything and all other vegetables nothing in human estimation the heads of gardeners were so crammed with zones and margins, and trusses and pips and beds, that there was no room for anything else, and the phenomena of the tulipomania were reproduced in a newer fashion, and no one was fully aware of the fact that the world had gone mad on the subject of Pelargoniums.

Now that we can again survey the subject calmly it will be observed that two classes of Pelargoniums remain in full favour with the public. The large-flowered show varieties and the large-flowered single Zonals take the lead, and they are pleasantly followed by a crowd of Ivy-leaved, double-flowered, and variegated sorts that are useful and beautiful, but no longer oppress us by their multitude and similarity. The Pelargonium Society has set up a severe standard of judging, and a variety must be distinct and good to pass through the

sieve. Moreover, the raising of varieties has been to a great extent reduced to scientific principles, and we obtain as a result new characters suggestive of the great extent of the field that still lies open to the adventurous spirit in cross-breeding. No one in recent years has contributed more directly towards the scientific treatment of the subject than our painstaking Treasurer Dr. Denny, of whose labours I propose to present a hasty sketch.

Dr. Denny commenced the raising of Pelargoniums in the year 1866, having in view to ascertain the influence of parentage, and thus to establish a rule for the selection of varieties for seed-bearing purposes. In raising varieties with variegated leaves, as also with distinct and handsome flowers, he found the pollen parent exercised the greatest influence on the offspring. The foundation of his strain of circular-flowered Zonals was obtained by fertilising the large starry flowers of *Leonidas* with pollen taken from the finely-formed flowers of *Lord Derby*. From 1871 to the present time Dr. Denny has sent out sixty varieties, and he has in the same period raised and flowered and destroyed about thirty thousand. These figures show that when the selection is severe, and nothing is allowed to pass that is not of the highest quality, there must be five hundred seedlings grown for the chance of obtaining one worth naming. The late Mr. John Salter used to say that it was needful to flower two thousand seedling *Chrysanthemums* for the chance of one worth naming. Therefore, if the comparison is of any value, it shows that raising Zonals is a very profitable business, the chances of success being four times greater than with *Chrysanthemums*. But Dr. Denny obtains more good things than he sends out, for he makes every year a selection of plants for seeding, and these amount to about 3 per cent. of the total number. It will be seen, therefore, that for every one sent out under name there are about fifteen equally good or nearly so, but for some reason or other they are not parted with, but are reserved to supply seed or pollen, and are then destroyed to make room for a new selection.

Amongst many interesting results of our friend's observations is one that strikingly confirms a suspicion that accompanies a study of Sweet's portraits—it is that some varieties assume the character and bearing of species, and by self-fertilisation reproduce themselves with peculiar exactitude. No one can doubt that many of the so-called species of plants, whether of Pelargoniums at the Cape or of Willows in England, are as truly hybrids as any that are raised in gardens. And this brings us to the question, What is a species? and the question suggests that if in treating this great subject I scarcely knew where to begin, I certainly know where to leave off. I confess I do not know what is a species—and so, thanking you for your kind attention, I now return to the golden silence.

LUCKNOW HOUSE, ADDISCOMBE.

THE above address will be by no means unfamiliar to members of the National Rose Association and other scientific societies. After acting as Judge in several classes at Croydon, and having the satisfaction of awarding a first prize to a very meritorious twenty-four of the invaluable Hon. Treasurer possessed by the National Rose Society, we adjourned to Lucknow House, where, after the rites of much hospitality had been duly observed, I obtained at last my much-wished-for introduction to see Mr. Mawley's wonderful garden with its three hundred Rose trees.

People talk of it being impossible to cut a good twelve on any given show day without possessing six or seven hundred Rose trees, and how very many now get into their thousands? yet here is a garden that had three hundred last year, and now has barely 380 plants, the flowers from which won more first prizes last year than I can well enumerate. To give one instance: while its master was starring it with some of them at Manchester, the spare blooms left behind went to a neighbouring local show, and with ease won a first prize for twenty-four, defeating, I think, five of the trade besides other amateurs.

Here, then, was the garden which I, with my eight hundred Rose trees, last year met at the National and was defeated, and again at the Alexandra with the same result. Why, the whole house and garden does not cover the space of half an acre, yet it has a south wall border of all the best Teas, enjoying the richest health, which anyone might be proud of. At right angles to this is a double row of robust H.P.'s—really robust is too feeble an adjective. The finest plants of all (a rapidly increasing plan) were all budded where they grow and never moved, the seedling Briar being the stock most favoured. Besides the richest viands and waterings weekly, twice a week the earth is turned over between the plants, thus carrying out Mr. George Paul's invariable exhortation, "Keep the hoe going," to something more than a pitch of perfection.

Tearing myself away from the Roses, I had just time for the glance round the scientific instruments for which Lucknow House is famous in a very wide scientific circle. And here I am distinctly out of my depth. There were two rain gauges, one of them only consulted once a month, which was of itself perplexing. Then a thermometer which went down a wooden well and came

up again, and showed the earth temperature at the daily depth of a foot. Then there was a stand of thermometers, the explanation of which would be bewildering could I hope to reproduce it. Then an instrument was shown me for weighing the rain, as if they had not had enough of it in the gauges! Last year must have given some employment. Then an anemometer—in fact two; then an instrument for registering the hours of sunshine, which pleased me most of all through its brilliant simplicity. Visiting it on the roof of the house was really an almost perilous process. I had observed with some dismay that the temperature on the grass was 70°. However, I had to follow “my guide, philosopher, and friend” up through a trap door into a little chamber under the slates, which he pleasingly suggested to me to touch. On emerging, all but failing, I gasped out an entreaty that he would test the temperature here. Of course a huge thermometer was immediately produced, and he calmly remarked that it was slightly over 100°. The Black Hole of Calcutta must have been cool by comparison. However, I was repaid by the heliograph, a large round glass globe, which acts as a burning glass on a long strip of blue card, placed daily beneath it, and graduated into hours division, which are traversed by a line of scorching whenever there is sunshine. I should have mentioned before that the interesting inmates of the garden wear tin helmets in wet weather, and the same with a white cap cover when afraid of the heat. That which I have attempted to describe is a marvellous instance of how high scientific faculties when directed to Rose-growing can make a great success out of very limited appliances—one more proof, if it were needed, that cleverness is only another word for a great faculty for painstaking. Like the first Cæsar—

“Nil actum reputans dum quid superabat agendum.”

“Counting nothing as done while anything yet remained over to be done.”

—A. C.

A WEEK OUT—KEW GARDENS.—No. 2.

CONTINUING my notes from page 44 I will first refer to the Orchids that were flowering in the national collection. These were *Vanda suavis*, *V. tricolor*, *Aërides affine*, *A. odoratum*, *Lælia purpurata*, *Epidendrum radiatum*, *E. expansum*, *Trochilus linearis*, grassy tufts; *Epidendrum virens*, singular green flowers; *E. variegatum*, green and black-barred flower; *E. ellipticum*, pink; *Cattleya Mossiae*, *Cœlogyne ochracea*, white and yellow, very sweet; *Brassia verrucosa*, green and white, very fine; *B. maculata*, yellow-barred; *Thunia Marshalli*, white, handsome; *Lycaste Deppci*, greenish white, yellow-spotted; *Masdevallia Lindenii*, pink; *Mesospinidium roseum*, pale rose, beautiful; *Lycaste aromatica*, yellow, fragrant; the lovely *Utricularia montana*, an epiphytal Bladderwort, growing in baskets, flowers white, with bright yellow palate, very beautiful; *Odontoglossum pulchellum*, white, purple-spotted; *Oncidium maeranthum*, immense spikes of large flowers, deep yellow, lip blotched with purplish crimson, very showy; *O. sphacelatum*, *O. leucochilum*, and *Maxillaria tenuifolia*. Of *Cypripediums*, *C. barbatum*, *C. Parishii*, and *C. longifolium*. In the *Sarracenia* house were *Drosera binata*, very pretty; *Sarracenia hybrida*, and the beautiful *S. Moorei* in good form.

Conspicuous at the entrance to the succulent house was the beautiful twining plant *Bomarea Carderi*, bearing pendulous terminal cymes of bell-shaped flowers of a pale rose or pink colour, the ends of the segments spotted with purplish brown; a very handsome greenhouse climber. In addition to a lot of grand *Agaves*, &c., were the lovely *Asparagus consanguineus*, with foliage finer than any Fern, a splendid plant for decorative purposes and sprays for cutting—finer even than *A. plumosus*; *Jatropha podagrica* with its gouty stem and fine orange scarlet umbel-like heads of flowers; and the old but very useful *Euphorbia splendens*. In fine contrast were *E. lactea* with huge stems and yellow flowers; *Opuntia monacantha* had grand deep yellow flowers, and *Sempervivum velutinum* had spreading bunches of yellow flowers.

Of Ferns I remarked in the tropical house *Gymnogramma trifoliata*, *Lygodium pinnatifidum*, *L. dichotomum*, and *Oleandra articulata* as fine pillar plants, the latter a creeping kind, and fine for overhanging rocks or baskets. In *Trichomanes* were *T. frondosum*, very fine; *T. alatum*; *T. trichodeum*, small, elegant, very beautiful; and the curious Liverwort-like *T. membranaceum*. *Hymenophyllums* were very fine, particularly *H. javanicum*, *H. hirsutum*, *H. ciliatum*, and *H. lineare*, *Trichomanes pyxidiferum* being very beautiful. These are grown under glasses.

PALM HOUSE.—*Higginsia Ghiesbreghtii* variegata was noticeable for its finely marbled distinct foliage and adaptability for decorative purposes. The Malay Apple (*Jambosa malaccensis*) with scarlet bottle-brush-like flowers produced freely from the old wood, and is only suitable for large houses from its tree growth. *Encephalartos longifolius* is a noble Cycad, very fine for conservatory,

also *Podocarpus cupressina* with Yew-like foliage. *Acalypha marginata* is one of the most distinct of this fine genus of decorative plants, and in a small state makes good table plants, having bronzy leaves margined bright rose. *Stigmaphyllon ciliatum*, a fine climber with yellow flowers; *Petræa volubilis*, twiner, with bluish purple flowers, very effective; and the singular *Vitis gongyloides* was noteworthy. *Crinum asiaticum* with white flowers and pink stamens was very effective and sweet-scented. *Echmea glomerata* with lovely blue flowers, which in contrast with the scarlet bracts are very pleasing, and *Sterculia ornata* had effective marked ornamental foliage.

AQUATIC HOUSE.—Here were the pink Sacred Bean (*Nelumbium speciosum*) and the yellow species (*Nelumbium luteum*), and pink and white Water Lily (*Nymphaea versicolor*) the blue-flowered *Pontederia cærulea*, and yellow-flowered *Jussiaea natans*, and *Limncharis Plumieri*, *Thalia dealbata* relieving the flat water surface admirably. *Ceratopteris thalictroides* thriving admirably treated as a semi-aquatic. The railing around the tank had trained to it *Ipomœa* (*Batatas*) *paniculata*, bearing large pink *Convolvulus* flowers, a fine climber where there is plenty of room. *Russelia sarmentosa*, semi-scandent, a pillar plant, bearing scarlet flowers, finer even than *R. juncea*.

TEMPERATE HOUSE.—*Eutaxia myrtifolia* with its pretty orange Pea-shaped flowers was very beautiful, and the highly ornamental *E. longissima* of pendant habit and narrow striped leaves. *Kerria japonica* variegata forms a highly ornamental shrub, profusely flowered (yellow); *Hydrangea japonica rosea alba*, a very neat-growing free-flowering plant for pots; *Rhododendron Jenkinsi*, white waxy flowers, and very sweet; as was also *R. Maddeni*, white; *Rhodochiton volubile*, purple Bellflower, a neat pillar plant; *Swammerdamia glomerata*, with heads of white flowers, a pretty evergreen shrub about 3 feet high; *Bossia linophylla*, drooping habit, bearing bright yellow Pea-shaped flowers profusely, very fine, contrasting grandly with the bright red flowers of *Boronia elatior*; and the pretty *Bauera rubioides*, rosy purple; *Clanthus puniceus* was fine as a pillar plant, bearing its Pea-flowers abundantly; *Ruscus androgynus* is the most graceful of all pillar plants for a lofty conservatory, its fine pendant foliage having a grand effect; *Coprosma lucida*, bright shining evergreen, loaded with yellow berries; *Malva cæpensis*, fine white eup-shaped flowers, very effective; *Fuchsia thymifolia*, very pretty habit and foliage, with beautiful crimson flowers; and the evergreen *Serissa foetida*, bearing profusely white semi-double flowers; the very fine *Viburnum plicatum*, with balls of white; and the *Funkia undulata* variegata, as fine for decoration as many plants more choice, rare, and expensive.—G. ABBEY.

YELLOW IN THE FLOWER GARDEN.

THOSE who write so strongly against bedding-out, or the scarlet-and-yellow style of summer flower garden decoration, never fail to point out the “vulgar” way in which Golden Feather, yellow *Calceolarias*, and other plants and flowers of this colour are employed; but I had no conception until a few days ago of the very little regard that is paid to the teaching of the “floral reformers.” Of all the colours used in the London parks and gardens none predominate so much as yellow. To such an extent is this colour employed, that in looking sideways at a series of carpet beds in Battersea Park scarcely anything but yellow can be seen, and to see a bed in any of the parks without yellow in it is quite the exception. At the Crystal Palace large circles of yellow *Calceolarias* take the eye from everything else; and altogether I should say country gardeners going to London for new ideas must return with the determination to employ yellow with more caution than ever. This colour in proper proportion may be adopted with the best results in many combinations, but, in my opinion it is one of the most dangerous colours to work with, and should never be employed to a very great extent. While on this subject I may say that some of the most pleasing beds of the season are those planted with a well-balanced mixture of white-leaved *Geraniums* and blue *Lobelia*.—J. MUIR, *Margam*.

THE CELERY FLY.

JUDGING from several inquiries on the subject that have reached us this week we fear that this insect is much too general. Last year many crops were ruined, and unless prompt measures are taken to examine the plants daily and remove the affected leaves or crush the maggots in them similar losses may occur this year. All our inquirers do not appear to know that the blisters on the leaves contain small green grubs, and that these grubs are the larva of the Celery Fly (*Tephritis onopordinis*). The grubs may be found in the leaves of the Celery in June, July, September,

October, and November; for there are two or more broods of them in the course of the year. The grubs, though less frequently, are found doing similar damage to the leaves of Parsnips. When full grown the grubs descend into the earth and remain in the chrysalis state until the spring following, when they give birth to the fly. This, the Celery Fly, may usually be found upon the leaves of the Laurel, hovering over flowers and resting upon palings in the sunshine, from the middle of May to the end of July. It is one of the most beautiful of the English two-winged flies. The general colour of the body, which is five-jointed, varies from rusty brown to shining black; head buff, with black hairs;

Fig. 18.

legs yellow; thorax (throat) sprinkled with long black hairs; wings black, with various pale spots; eyes green. The whole length of the insect is not more than one-sixth of an inch, and its wings when outspread barely half an inch across. The cross lines in our woodcut show these proportions as well as the insect magnified. The motions of this fly are very peculiar; seated upon a leaf in the sunshine, the wings are partially extended, yet partially elevated, and it has a sidling kind of motion.

We shall be very glad to hear from our practical correspondents the best modes of preventing the attacks of this destructive insect, while there is yet time to preserve the Celery crops from serious injury.

FRUIT HOUSES.

Pines.—The fruits of plants started early in the year will, as regards the early varieties, now be ripened off, and later varieties which were started at the same time will be sufficiently advanced to allow of the plants being removed to a vinery or other house with a somewhat dry atmosphere. This will afford additional space to the successional plants; and in preparing beds at this season judgment and experience are required, as too much heat at the roots of the plants is very injurious. Fermenting beds which were renewed by liberal additions of fresh material in spring will only require turning over to a depth of about 18 inches, whilst those not renewed at that time should have a foot of fresh tan incorporated with the old. Suckers from the plants alluded to above may be potted so soon as the house for receiving them is in readiness—viz., a close moist pit, having a fermenting bed with a temperature of 90°. The fibrous loam employed in potting should be rammed firmly in the pots and round the base of the suckers, watering once and plunge without delay, covering the soil in the pots with the plunging material so as to prevent it becoming very dry at the surface. With this precaution water will not be needed again until new roots are formed, but a light syringing occasionally will be beneficial. Effectual shading will be necessary when the sun is powerful, ventilating a little at 80° to 85°. The suckers started in June should be transferred to larger pots before the roots become very much matted together; 9 or 10 inches will suit Queens, and 11 inches others of stronger growth. Water the plants immediately after potting, and plunge them in a bed having a temperature of 90° to 95°. A batch of suckers should be reserved on the stools for starting at the beginning of September.

Cucumbers.—The rainy weather has not been favourable to Cucumbers, and the absence of sun has resulted in a plentiful crop of yellow

fruits and abundance of mildew in the foliage, with canker both at the collar and in the old growths, particularly where fire heat has been discontinued. In such weather gentle fire heat by night is advisable; dusting freely with flowers of sulphur for the mildew, whilst for canker the efficacy of quicklime has often been pointed out. After a period of dull weather Cucumber plants are liable to flag and have the leaves scorched, which should be prevented by judicious shading. Pot off the autumn fruiters, pinching out the growing point at the second rough leaf, completing the preparation of fermenting material and soil, removing the old plants preparatory to a fresh start; it being essential that the house be thoroughly cleaned. The only means of securing a free and fruitful growth is to pay close attention to ventilating, watering, shading, stopping, and well thinning out the growths periodically. In fine weather water copiously, and syringe freely between 3 and 4 P.M. If plants be now placed out in frames they will afford fruit in late summer and to a late period, due attention being given to line the beds when the weather is cold.

Melons.—Much that has been advised for Cucumbers applies to Melons. In wet sunless weather fire heat is necessary for plants setting as well as those ripening their fruits, as without dryness neither a good set nor a good flavour is to be had. The syringing should be discontinued for plants in any stage of growth in wet sunless weather, and more than ordinary vigilance should be exercised in looking for canker and cracked fruits. The last batch in pits and frames should be growing freely, one leader being trained to the back and the other to the front. The soil cannot be too firm to check the tendency to luxuriant growth, which in young plants at this season is very marked. The seeds for the last batch of plants should be sown without delay, which will afford fruits as late as they can be had of fair flavour. The plants for fruiting in October should be placed out without delay in a light house, and where plenty of heat can be afforded when necessary. Plants setting their fruits in pits or frames will require to have moisture sparingly applied, not, however, permitting flagging. In fine weather syringe freely, and afford a plentiful supply of water to plants with crops not actually in the setting or ripening stage, keeping the growths well thinned except when the fruits are setting, when the growths as the blossoms are impregnated should be stopped one joint beyond. Earth-up the roots of plants which have just set their fruits.

FLOWER GARDEN.

The weather has been such that plants delighting in moisture have had enough to carry them on for a long time, and where mulching has been practised little if any further watering will be necessary. Flowers, of course, in wet weather are few except Violas, which appear all the brighter, but Calceolaria flowers become filled with water and drop off. Examine the beds frequently, removing dead or decayed leaves and flowers; and to have Verbenas fine they should be frequently picked over, and kept well thinned by pinching back a portion of the shoots. Carpet-bedding plants should be regularly pinched and pegged twice a week, as such free-growing plants as *Mesembryanthemum cordifolium variegatum*, *Stellaria graminea aurea*, and others soon encroach on plants of less vigorous growth, and the effect depends in a great measure upon the lines forming the different designs being kept clear and distinct.

Continue sowing and pricking-out hardy perennials, such as Carnations, Picotees, Brompton Stocks, Wallflowers, &c., as soon as large enough to handle. Pansy seed should also be saved and sown, and cuttings inserted, also Violas for spring flowering. If the flowers of Marigolds and Asters are required extra fine the buds should be freely thinned, reserving the most promising only. Dahlias and Hollyhocks, and plants having a large leaf surface for the wind to act on, should be securely staked as they advance. Roses have had a hard time, and are now being attacked with mildew as they were in the spring with aphides. Syringe the bushes with a dilution of pentasulphide of calcium, employing a wineglassful to a gallon of water, or dust with flowers of sulphur. Continue budding, and insert cuttings under handlights in gentle heat. Tropæolums and Clematises should be trained. The latter are now in great beauty, but unfortunately are not so continuous-flowering as could be wished, and although fine for bedding they are not in at the right time or only flower for a

short time, and in late summer when most required they are over. The best places for them are archways, old stumps, and rockeries.

PLANT HOUSES.

Stove.—Climbers trained to the roof wires should be frequently examined, thinning and regulating the growths, or they will become so entangled as to render the work difficult, besides doing injury to growths it is desirable to retain. Some roof climbers are a harbour for insects, as they are not so forcibly syringed as to dislodge such pests as mealy bug and red spider. The roof climbers should of all others be kept free from insects by the prompt application of remedial measures. *Stephanotis*, *Ixoras*, *Dipladenias*, and similar plants done flowering should be similarly treated for mealy bug and scale, &c., as the *Gardenias*, giving a second or third dressing at intervals of a few days or before the young growths are started, though at the strength named it does not injure the young foliage. Young plants of the above named should be moved into larger pots if necessary, and growth encouraged as for *Gardenias*.

Eucharis amazonica.—Plants that flowered early and have made and completed a growth, should be rested, withholding water and keeping them rather cooler for about a month or six weeks, affording sufficient water to keep the leaves from injury, and after this, being returned to heat, they will quickly produce flowers. Plants that flowered but recently should have every encouragement to induce growth by the supply of plenty of moisture both at the roots and in the atmosphere.

Winter-flowering Plants.—*Aphelandra aurantiaca*, *A. Roezli*, *A. cristata*, and *A. nitens*, *Centropogon Lucyanus*, *Eranthemum pulchellum*, *Gesneras* of the *exoniensis* and *zebrina* type, *Thyrsacanthus rutilans*, *Scutellaria Mocciniana*, and *S. pulchella*; *Sericographis Ghiesbreghtiana*, *Plumbago coccinea superba*, *Poinsettias* and *Begonias*, should be encouraged to make all the growth possible by keeping them near the glass in a growing temperature, and syringing them every evening. *Euphorbia jacquiniæflora* is of straggling growth, and may be improved by stopping the shoots, but it should not be done after the beginning of August.

Anthurium Schertzerianum.—Plants of this Aroid will now have passed their principal flowering; and although the plants that flowered early have a disposition to continue throwing flowers, the next month or six weeks is a good time to pot large plants. Employ fibrous peat in lumps as large as an egg, rejecting the small by sifting which should form half the compost, the other half being composed of equal parts sphagnum, charcoal, and potsherds broken moderately small, with a little sand. Good drainage is necessary, as when growing very plentiful supplies of water are required. *Achimenes* flowering in baskets will require liberal supplies of liquid manure to keep them in good condition. *Gloxinias* need similar attention.

NOTES ON VILLA AND SUBURBAN GARDENING.

FRUIT HOUSES.

Grapes.—The thinning of all late unforced *Grapes* must be completed before the berries become crowded. Fully two-thirds of the berries in most instances should be removed, especially if those retained are expected to keep well. Close-growing free-setting varieties especially require careful thinning. Syringing overhead is usually discontinued after the flowering time, but the walls and floors are frequently damped to insure a moist growing atmosphere, which also helps to ward off the attacks of red spider. This insect is very apt to appear after the syringing is discontinued, especially on heavily cropped Vines should the latter receive an insufficiency of moisture at the roots. The insects are very minute, but they are easily discovered by the yellow tinge which the foliage assumes on the under side. Where they are thus found active measures must at once be taken against them, or they will materially affect the finishing of the crop. Syringe the foliage forcibly early in the mornings, and again when the house is closed for the evening. Clear water, filtered if possible, must be employed, and the bloom on the berries will then be unaffected. Syringing must be discontinued when the berries are commencing colouring, at which time ventilation may be provided during the night. Water inside borders frequently; once a week is not too often, especially where the borders are limited. Vary the

waterings with either liquid manure or with some artificial manure. Employ the latter very carefully, as they are really injurious if used to excess.

Tomatoes.—Those being grown either in pots or boxes will now require abundance of water at the roots, as if allowed to become very dry the newly set fruit are liable to become misshapen, and it will also induce premature ripening in the case of larger fruit. Supply liquid manure frequently. When the first bunches of bloom are set give the plants a good top-dressing, consisting of equal parts of rough turfy loam and well-decomposed manure, into which they will readily emit fresh roots. See that the original soil is sufficiently moist previous to top-dressing, and afterwards examine it frequently. All side shoots should be removed, or they will rapidly smother the bloom. Take the tops off those plants of large-fruited varieties which have perfected three bunches of bloom, but the small-fruited varieties, such as *Vick's Criterion* and *Nesbit's Victoria*, may be allowed to grow on. Thin out the bunches if large fruit are in request.

Cucumbers.—Many are now growing these in their houses, and, as with the *Tomatoes* and *Grapes*, find them both ornamental and useful. Keep the roots active and near the surface by giving a top-dressing of turf and manure occasionally. Water frequently with farmyard liquid manure; failing this, sprinkle a little artificial manure over the surface of the bed and water it in. Thin out the growth if at all crowded, pinch back the young shoots to second joints, and avoid heavy cropping, red spider to be kept down by syringing overhead morning and evening and frequent damping of the floors and walls; and thrip—which also is very quick-spreading and injurious—is most effectively dislodged by an occasional fumigation with tobacco.

GREENHOUSES AND FRAMES.

Coleuses.—The small varieties are best grown rather flatly, but the larger-foliaged varieties make excellent pyramids. Give the former 5 or 6-inch pots, and the latter 8 or 9-inch pots, and water frequently with liquid manure when the plants are well established. Any soil may be used providing the pots are well drained. Keep the plants well pinched back till a good head is formed, taking up the central shoot in the case of pyramids, and for a time pinch back all the side shoots. Syringing overhead injures the colour of the foliage.

Gloxinias and Begonias.—Seedling plants in small pots should be shifted into 4-inch pots. Employ a compost consisting of equal parts loam and leaf soil with some sand for the *Begonias*, and two parts loam to one of leaf soil and sand for the *Gloxinias*. The latter should not be potted deeply, and though they like plenty of moisture in the atmosphere none should be placed on the foliage. Do not pinch back the Tuberous *Begonias*. Those *Begonias* intended for flowering during the winter should be pinched back to render them stocky, and gradually shifted on; such species as *B. nitida* and *B. fuchsoides* into 10-inch pots, and such as *B. Digswelliana* and *B. Saundersoniana* into 5 or 6-inch pots. Loam and peat, or loam, leaf soil, and sand, will suit them well. If *B. Weltoniensis* is wanted in flower in the autumn pinch back the plants and shift them on.

Chrysanthemums.—The tops of old plants strike readily in a little heat, and will, providing they are not pinched back, flower freely. Place about five cuttings of any one variety in 3-inch or 4-inch pots, and one in the centre. Keep the plants rather close and shade till rooted, when they should be gradually hardened, and eventually shifted into 6-inch pots and placed outside. Employ rich loamy soil, to which may well be added some crushed oyster shells and a sprinkling of soot, both for these and the older plants, which should now receive their final shift. Return these to an open sunny spot; water regularly. Place stakes to standards, and rub out all their side shoots.

Miscellaneous Plants.—Specimens of the large-flowering *Pelargoniums* that have bloomed should be placed in a sunny open spot and ripened off by gradually withholding water. Young flowerless growth struck at this time can easily be grown into specimens for next season. They will strike in light soil containing plenty of road grit on a greenhouse shelf. Sturdy cuttings of free-flowering *Zonal Pelargoniums* struck in the same way, and afterwards kept in 4-inch

pots in a sunny spot, topped once and not allowed to flower, will give a good supply of bloom in the early winter months. Place older plants also in a hot position, and pick out bloom buds as they appear. Keep young plants of *Browallia elata* closely pinched back, and shift into 5-inch pots. These also should be in an open position. They are useful winter-flowering plants. Strong clumps of *Spiræa japonica* should be divided, and either repotted or, better still, be planted out in moderately rich soil and lifted in the autumn as required. They are very suitable for the herbaceous border, as they are perfectly hardy, in the southern counties at all events. Plants treated as above have surpassed imported clumps either forced or otherwise. Bright sunny positions will be found injurious to *Cinerarias*. Keep them growing at the back of a north wall. Old plants of *Cyclamen persicum* did not succeed well where planted out during the last season, neither is it advisable to place them out this season. Shake them out and repot into pots varying in size according to the corms; a 6-inch pot is suitable for the largest. Employ soil consisting of two parts turfy loam and one of leaf soil and well-decomposed manure, with an addition of charcoal and sand. The pots should be well drained and the corms about half buried in the soil. They will do best in a cold frame, but will succeed in the open. Keep young plants growing freely, they will succeed in a half-spent hotbed. A cold frame is also suitable for Chinese *Primulas*, or they may be grown on a greenhouse shelf. Roses in pots ought to be out in an open spot, and should be kept supplied with water.

Camellias.—These also may now be repotted. Employ soil consisting of equal parts of coarsely broken turfy loam and peat, with some silver sand and charcoal, clean pots well drained, and pot rather firmly. Treat unhealthy plants in a manner similar to that advised for unhealthy *Azaleas*. Syringe them frequently, and do not remove them from the greenhouse before the buds are set. An occasional supply of liquid manure given to well-rooted plants not requiring to be repotted will materially assist them in the formation of fine bloom buds.

TRADE CATALOGUE RECEIVED.

Osborn & Sons, Fulham, London.—*General Catalogue of Plants.*

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Botanical Work (*Flora*).—If you enclose a stamped directed envelope to Professor Oliver, The Royal Gardens, Kew, that gentleman will no doubt supply you with the information you require.

Decorative Pelargoniums (*J. W.*).—The flowers you send are decidedly handsome both in size and colour, but they appear somewhat rough and irregular in form, though that may be partly due to the packing. It would probably prove a useful variety for decorative purposes.

Peaches Decaying (*J. E., North Wales*).—The fruits have been punctured by an insect of some kind, which if you can find and forward to us we will endeavour to tell you its name, and furnish you with some information relative to its habits.

Rushes for Securing Rose Buds (*W. W.*).—The reference which you require will be found under the heading of "French Notes" on page 312 of vol. xxxvii. of this Journal, the issue of October 16th, 1879, where "D. Deal," has described the use of Rushes in the nursery of M. Margottin at Bourg-la-Reine.

Grapes Crushed (*P. J.*).—If you will send us berries packed in a small box, so that they arrive in the same condition in which they were sent, we will endeavour to answer your inquiries respecting them. Those sent loose in a linen bag came to our hands a flattened mass, and it is impossible for anyone to arrive at any conclusion as to their state when cut from the Vines.

Garden Expenses (*A Young Gardener*).—All proper expenses you incur, including the cost of stamps and paper employed in writing letters in the discharge of your duties, should be defrayed by your employer. In regard to the

other question you have no claim, and the "custom" you allude to is not by any means generally established.

Purchasing Plants (*J. P., Dublin*).—It is impossible for us to recommend nurserymen; it would be manifestly unfair for us to do so. By reading the reports of shows anyone may readily determine those growers who make a speciality of any particular class of plants; besides, such growers always advertise in our columns.

Heating with Pipes below the Boiler (*R. W.*).—You will find the communication to which you refer on page 98 of our last volume, the issue of February 5th of the present year. If you do not possess the number it can be had from the publisher in return for 3½d. in postage stamps, and a request for No. 984 of the Journal. The plan of heating there described answers well when rightly carried out.

Fungus on Roses (*M. J. L.*).—The leaves are seriously affected with the black fungus. Syringe them with a solution of soft soap, 5 or 6 ozs. of soap being dissolved in a gallon of water; or nicotine soap, 4 ozs. to the gallon, and when wet dust the affected parts with sulphur. Another remedy is to sponge the leaves with 2 ozs. of blue vitriol (sulphate of copper) dissolved in hot water, and added to two or three gallons of cold water.

Cucumbers Not Setting (*Dan*).—Your frame is probably too moist and cold at night, and the growths, perhaps, too crowded. The fault is not in the soil. The weather of late has been very unfavourable for Cucumbers. Keep the growths thin and the surface of the bed drier, not watering through a rose to wet the flowers and fruit, which should rest on bits of slate or glass, not on the soil.

Paraffin versus Ants (*W. A. B.*).—We know that paraffin will drive away ants when poured on their nests, but it is dangerous applying it in an undiluted state to the soil in pots and close to the stems of plants. Your mode of saturating manure with the oil, and applying as a top-dressing, is safer than pouring it into the soil. We advise caution in the use of this powerful "insecticide," as we have seen both Vines and plants killed by employing it injudiciously.

Aniseed Tree (*Young Gardener*).—You are right, there is a shrub known by that name. Its botanical name is *Illicium anisatum*, the fruit having the flavour of anise, being used as a spice in Chinese cookery; there are other species, and the seed of *I. religiosum* is burnt as incense in Chinese temples. They are half-hardy evergreen shrubs, and are increased by cuttings of the young ripened shoots in sand under a glass in summer; by layers, from a stool in a cold pit, where they generally remain two years before being removed; sandy loam and peat. They require the protection of the cold pit or greenhouse in winter, though *I. floridanum* has stood out in many places with but a slight protection in severe weather. All the species we have named are natives of Japan.

Peaches "Woolly" (*P. T. B.*).—Dr. Hogg, though an excellent Peach of high colour when grown out of doors or on walls protected with glass, the trees not been forced, yet it is not always of superior quality when ripened with the aid of artificial heat. The other varieties you name, especially Royal George, are usually of excellent quality when slightly forced; but to have the fruit in the best condition the trees must be carefully and properly watered and ventilated, and they must not be overcropped. If you have carried out the instructions that have been frequently given in "Work for the Week" we think your trees have been too heavily cropped. A greater number of Nectarines would ripen well on a tree than would Peaches on a tree of the same size and vigour.

Grapes Dropping off (*A. J.*).—What you term cankering is certainly not the result of any pilfering to which the bunches may have been subjected, nor is it a case of shanking. So far as we can judge from the small bunch before us your Vines are in a very debilitated state. Either the roots have not access to the food they need or have not strength to appropriate it. What is the average circumference of the fruit-bearing laterals, and the diameter of the foliage? We suspect that like the bunch and berries they are small. Very possibly the Vines have received some check and injury by a low temperature and moist atmosphere, but we think the chief cause of the evil is a lack of the support that is requisite to the production of stout footstalks and large fruit.

Rose Leaves Blistered (*A Munster Subscriber*).—The foliage is deficient in texture, and cannot resist the effects of the sun. The blistering is the most marked on Roses growing in poor soil, and especially on plants that have long occupied the same positions, and consequently exhausted the soil. Blistering is also caused in some instances by small grubs eating the foliage. Give your Roses copious supplies of liquid manure, and enrich the surface with manure to retain the moisture in the soil; also examine the growth closely, removing any maggots that you can find. At the winter's pruning remove all the weak wood entirely, and shorten the young and straggling shoots to induce more vigorous growth.

Packing Bulbs for New Zealand (*G. O. S.*).—The bulbs should be taken up when the foliage decays and dried of superfluous moisture, for if moist or even damp they would in all probability decay before reaching their destination. We know of no better material for packing them in than the husks or chaff of Buckwheat; failing this soft and perfectly dry Oat chaff would probably answer very well. A layer of the chaff should be placed at the bottom of a zinc-lined case, then a thin layer of bulbs, which should not quite touch each other, followed by a thicker layer of chaff, and so on until the case is quite filled, the whole being shaken and made firm as the work proceeds. If anyone who has had experience in packing bulbs for the Antipodes can state a better plan we will readily publish it.

Peach Trees Gummed (*C. S.*).—As only the trees in pots are unsatisfactory, those trained on the back wall being healthy, and as the former were placed in the open air after fruiting last year, we conclude that the growth was not matured owing to the singularly wet and dull weather to which they were subjected; and further, if the trees were left outdoors during the winter or until December, they were probably injured by the sudden and severe frosts that occurred in November. Keep the growths thin, removing any that are very luxuriant, and expose the trees to all the heat, light, and air possible to insure the maturation of the wood, and your trees will probably recover. Do not place the trees outside quite so soon, and house them a little earlier than usual, the time being determined by the weather.

Lettuces not Hearting (*J. M. C., Chester*).—Possibly your plants have received a check by transplanting during the dry weather that prevailed during April and May, or the soil may be light, thin, and poor. To prevent premature seeding no plan is equal to that of sowing the seed very thinly in drills where the plants are to remain until cut; but it is important that the soil be rich and deep, and that the plants be thinned very early, so that no crowding occurs when they are young. Many Lettuces are spoiled by the seed being sown too thickly, and the plants afterwards left too long in the seed bed before they are trans-

planted. If none of the circumstances suggested have promoted the premature "piping" of your Lettuces we attribute the cause to the seed not being of good quality. Last year was most unpropitious to the ripening of seed, and sound and well-matured seed is the first essential to satisfactory crops. If imperfect seed is the cause of your failure it does not necessarily follow that the seedsman is blameable, for we know that the chief nurserymen and seed firms made special efforts to obtain the best stocks that were procurable for supplying to their customers.

Insects on Vines (*J. S. S.*).—Without seeing the insects—and there are none on the leaves sent—it is impossible for us to tell you what they are. But whatever they are you appear to be able to destroy them, and you cannot do better than continue the treatment you have found effectual. Timely applications of quassia water might render the shoots and leaves distasteful to the insects and prevent their attacks, which is better than enre. We must inform you, however, that the numerous warts on the larger leaves are not caused by insects. Your vinery has been kept too close and moist at some time, and ventilation has been delayed too long in the morning. One leaf is certainly scorched, and the whole of them indicate that the ventilators have been closed when there was much moisture in the atmosphere when the sun has been shining on the house. Never close the house entirely, but leave the ventilators open an inch or two all night, increasing the ventilation very early in the morning in advance of the rising temperature, and do not syringe the Vines or damp the house late in the afternoon. Had you adopted this practice throughout the season your Vines would not be in the condition they are now; they will not, however, we think, be seriously injured if you keep them free from insects, admit more air, and employ less moisture. We do not think the man who supplied the Vines can be properly blamed for their present condition.

Melons Unhealthy (*Idem*).—The leaves sent are much infested with the red spider. If the plants are trained on a trellis syringe them forcibly; if in a frame sponge the leaves, especially the under surfaces, with a strong solution of soft soap. The red spider, not the fungus, is the cause of their present very unsatisfactory state.

Cucumbers Unhealthy (*J. S., Nottingham*).—The portion of roots you have enclosed enables us to say that they are affected with the "disease," all particulars of which you will find, with an illustration, on page 74 of No. 852 of the Journal, which can be had from the publisher in return for 3½d. in postage stamps. Mr. W. G. Smith there states a remedy, "salms," and he is supported by Mr. D. T. Fish, but other cultivators consider that to attempt applying a remedy to Cucumber roots badly affected with excrescences is to waste time needlessly. One who has had great experience gives the following advice in cases similar to yours:—"Raise fresh plants from seed, not from cuttings of the affected plants, which destroy. Remove the whole of the soil, give every part of the interior walls a thorough dressing with hot limewash, scour the whole of the woodwork, close the house, and fill it with fumes of sulphur; then put in some fresh sweet soil, and fresh plants will probably prove quite healthy." We should be glad if those who have Cucumbers thus affected would try carefully experiments with paraffin, as it is just possible that a strength might be found that would kill the vibrios, nematoid worms, without destroying the plants. It must be understood, however, that those trying such an experiment must be prepared to sacrifice some of the plants, but this would only be killing them a few weeks before they succumbed to the disease. We should commence with applying the paraffin at a strength of a fluid ounce to a gallon of water, increasing the strength in different portions of the bed. The result of such an experiment carefully conducted would be interesting and might be useful.

Melons not Setting (*F. J.*).—Plants growing in frames placed on manure are not unfrequently very exuberant from the roots of the Melons passing through the soil into the rich compost below, and over-luxuriance is not favourable to the setting of the fruit. The only course we can recommend you to pursue is to remove some of the exuberant growths, so that those remaining are so thickly disposed that the sun can shine on every leaf. Tread the soil very firmly, being very careful not to injure the foliage, and do not give any water for some days, or only just sufficient to prevent the foliage flagging. If the ends of the main shoots are cut off when they reach nearly to the sides of the frame, the axillary growths following will produce pistillate flowers, to which pollen should be applied from the staminate an hour after the frame has been opened in the morning. The fruit-bearing laterals should be pinched at one leaf beyond the flower immediately the latter is seen and before it expands. By carrying out this advice we think you will yet obtain some Melons. No growth should be permitted except that for fruit-bearing, and all laterals should be removed except those on which the fruit sets. We doubt if you will be able to ripen a second crop from the plant now swelling its fruit, but you may do so if the autumn proves warm and bright. After cutting the fruit carry out the advice as to pruning and stopping above recommended, and encourage fresh growth by keeping the frame close and moist until flowers appear on the plants, then maintain a drier atmosphere until the fruit has set, afterwards keeping the frame as warm as possible consistent with efficient ventilation. We thank you for your remarks of approval.

Lapageria rosea Culture (*A. B. S.*).—This plant is not difficult to cultivate either in a pot or border. Good plants can be grown in 11-inch or 13-inch pots, the shoots being trained to a trellis, a flat one being most suitable. Whether grown in a border or pot, good drainage should be secured. A border 4 feet long, 2 feet wide, and 2 feet deep, clear of the drainage, will support a large plant. The drainage should be, as already stated, very good, for, during the season of growth, the watering must be plentiful, and at no time must the soil be allowed to become dry. During the growing season a plant in a large pot will require a gallon of water daily, and one in a border thrice the quantity.

Names of Plants (*J. Mark*).—The two large leaves appear to be those of *Malva moschata*. The fragment of a fleshy leaf resembles an *Echeveria*, but such diminutive scraps are quite insufficient for identification. (*G. O. S.*).—The plant is *Veratrum nigrum*, commonly known as the Black Hellebore, though it is by no means related to the true Hellebores, being allied to the Lilies. It is a native of Central and South Europe. (*E.*).—We only undertake to name species, not varieties, of plants, which are too numerous and similar, and can only be determined by comparing them with others in a large collection. The *Coleuses* you have sent are not species but varieties, yet as we recognise 2 as *Ajax*; 3, *Beauty of Fife*; 4, *Murrayi*; and 5, *Beauty of Widmore*, we name them for you. Send leaves of the others to the nurseryman from whom you purchased the plants. (*C. S., Forfarshire*).—1, *Knaulia arvensis*; 2, *Scorzonera hispanica*; 3, Probably a species of *Geranium*, but the specimen was too much withered for identification; 4, It is a *Centaurea*; 5, *Cherophyllum sylvestre*; 6, *Stachys palustris*. (*R. H. C.*).—*Streptocarpus Rexii*. (*Mrs. Davies*).—The fleshy plant is *Sedum azoicum variegatum*, the other is *Campanula fragilis*. Stop the shoots of *Rivina humilis* if you wish to obtain bushy specimens.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE ROYAL COUNTIES (HANTS AND BERKS) AGRICULTURAL SHOW.

(Continued from page 59.)

OUR last week's report concluded with remarks upon the Jersey or Alderney classes; but the Guernsey, being also a Channel Island breed, we must consider the merits of these and two other breeds which were exhibited on the occasion. For the best Guernsey bull of any age, and under two years old, with two entries and one entry respectively, first prize for bull of any age was awarded to Major A. C. Macleay of Lyndhurst, Hants; the second to Mr. J. Carter, Privett Lodge, Gosport. They were both very good animals of the breed, but they do not gain public estimation, the chief difference between them and the Jersey breed being that the former give richer milk, but less of it; in fact, their milk is commonly employed in some dairies for the purpose of colouring the butter. The bull under two years of age which received the award belonged to the Rev. J. G. Nichol of Micheldever, Hants, and we thought it a useful animal, and rather superior to the older animals in the former class, showing as he did all the qualities of the breed, with a good outline and correct form. For the best Guernsey cow, six entries, first prize given to the Messrs. Wooldridge of Woodcote, Chichester; the second prize was taken by the Rev. J. G. Nichol. Both the prize animals, as well as the reserve number in this class, were good specimens of the breed, and we think with some extra attention in the selection of this stock that they may be reared so as to lay on fat during the milking period, and by judicious feeding may afterwards be turned to advantage by sale as fat animals. For Guernsey heifers under three years old, two entries, both prizes were taken by the Messrs. Wooldridge with very promising animals, and capable of producing stock of better outline and aptitude to fatten than we have yet seen of this breed if judiciously selected, with the object of obtaining extremely rich milk also.

Ayrshire Cattle.—For the best bull the first prize was given to Mr. G. Ferme of Streatham Hill, Surrey. This animal represents very fairly the breed, which is very hardy, and in various districts in Scotland they are able as dairy stock to bear the effect of the climate better than any of our English stock. For the best Ayrshire cow, eight entries; and for Ayrshire heifer, two entries.—In both these classes the exhibits were the best specimens of the breed we have seen, Mr. G. Ferme taking all the prizes with a class of stock which are great milkers, and will be more appreciated when they are better known, for in the various counties where the land is poor and the climate cold and stormy we generally find a crossbred or nondescript stock, which are anything but profitable as dairy cattle. But for the poorest and most exposed districts we can with confidence recommend the Ayrshire cows as the best and most profitable dairy cattle. **Brittany Cattle.**—There were classes for this breed, but they neither attracted much competition nor attention from the visitors to the Show-yard, for we find that the other milking breeds offer superior advantages.

Horses for Agricultural Purposes.—These usually form one of the most popular features of an agricultural exhibition. For the best cart stallion foaled before the year 1878 the first prize was taken by a splendid specimen well adapted for raising stock for farming purposes, being of good size, with clean legs, and very active. This animal was exhibited by Col. R. Loyd-Lindsay, V.C., M.P., Lockinge Park, Wantage, Berks. This horse also received the

champion prize as the best cart stallion in the Show-yard. The second prize was taken by Mr. J. S. Hodgson, Haslemere, Surrey. The third prize was awarded to Mr. E. A. Caldicutt, Court Farm, Reading, Berks, for a horse which we thought ought to have been placed second instead of third, for it was a magnificent animal, and stands as No. 276 in the "Pedigree Stud Book" of the English Cart-horse Society. Now, this stallion is of immense power, although not high enough for a London dray horse, yet he is over 16½ hands in height, and of substance in proportion. We heard it stated that he was placed third because he had large hocks. We view this matter as merely exhibiting joints of extra muscular power, for when the legs are flat with soft silky hair the large hocks do not indicate any constitutional tendency to grease or joint humours, so common to horses with big bony round legs, and padded with thick coarse hair. What we also admired in this animal was that, notwithstanding his great weight and power, he was as active as possible—certainly the most active of the farm horses shown, and this is the style and type of animal that we have always recommended to the notice of the home farmer, as being capable of drawing a plough in all summer work, or with two such to a double-furrowed plough. This we contend is the only true farm horse economy, for such an animal in ordinary draught or team is equal to pull 25 to 30 cwt. with ease. Her Majesty the Queen exhibited a well-bred Clydesdale stallion in this class, but it was not noticed by the Judges as commended or reserved number, although he was of full pedigree, and numbered in the "Stud Book" 1252. For the best cart stallion foaled in the year 1878 the first prize was awarded to Messrs. E. and A. Stanford of Ashurst Steyning, Sussex, for a remarkably promising Clydesdale stallion just under two years of age, which was much admired for its correct form and activity; in fact, just such an animal as many noblemen and gentlemen should possess and keep on the home farm for the use and benefit of the tenantry and farmers of the district, charging only a moderate price for service. The second prize was taken by a Suffolk stallion two years and two months old, belonging to Lord Northbrook of Stratton Park, Micheldever, Hants. This horse was very active but rather light, and wanting in substance for agricultural purposes. The third prize was given to a stallion of Clydesdale origin, bred and exhibited by Mr. William Drewitt of Bramley, Surrey. This was a very fine animal with plenty of substance, flat legs, and capital action, and we thought ought to have been placed second instead of third, because this breed and style of animal are of better constitution than the Suffolks generally, and will continue in farm work much longer. Her Majesty the Queen took the reserve number with a fine and well-bred Clydesdale stallion two years old, bred at the Shaw Farm, Windsor, and it was no discredit to be so placed in the company of such remarkable animals as formed this class. Class 18, for the best gelding or filly foaled in the year 1878, eight entries. First prize given to Messrs. E. & A. Stanford, who also held the reserved number and a high commendation, thus showing that their style and type of horses were held in high estimation by the Judges. Mr. J. S. Hodgson took second prize with a well-bred animal. Her Majesty the Queen exhibited two animals in this class, one of which was commended, and justly so, for both were Clydesdale fillies of great excellence. Class 19, for the best entire cart colt foaled in 1879, four entries, Messrs. Stanford again took the first prize and the reserved number in this interesting and promising show of youngsters, Mr. Wm. Drewitt taking the second prize. Class 20, for the best filly foaled in 1879, four entries. Again Messrs. Stanford took first prize and reserved number, the second prize being awarded to Mr. W. B. Stubbs of Alresford, Hants. Class 21, best mare and foal, and Class 22, best mare for breeding purposes. In both these classes, although the entries were four and five respectively, Messrs. Stanford took the first and third prizes in the former class, and first prize and reserved number in the latter. This must indeed be considered a great achievement at an exhibition wherein we do not hesitate to say that all the best animals known of the different ages to be found in the southern counties were entered, and it establishes beyond doubt that Messrs. Stanford's stud of Clydesdale stock is not only worthy of the attention of all breeders of farm horses, but that they exhibit a uniform type and style worthy of imitation throughout the kingdom, for this stock is of long standing reputation as well as of great present success in the show yard. We will pass over the hunters exhibited by thirteen competitors in Class 23, because the remarks which we propose to make in Class 24, referring to hacks, will for the most part apply with equal propriety in both classes. In the class for hacks or horses fitted for general purposes there were twelve entries. First prize awarded to Mrs. G. Prior, Horndean, Hants; second prize to Mr. H. A. Martin, Cosham, Hants. Both these horses were well-finished animals as regards outline and shape, and well worthy of the

prizes they obtained. We wish, however, to say that all the animals taking prizes in the hunter and hack classes were exceptionally good in themselves, but in the classes to which they belong—taking the breeding of these animals as compared with the hunter and hack horses of forty or fifty years ago—they are altogether different animals in shape, power, and endurance compared with the horses of that period. The old style and formation of both hunters and hacks has been crossed out by the racing or pure "blood" stock, and instead of the strong, short-backed, weight-carrying animals we have now and then a good animal, but generally a generation of nondescript animals with inferior legs and weak constitutions. They may, however, in all their variations answer the purpose of the breeders to some extent, for the demand for them is now divided between the hunting and harness horses and that which draws the tradesman's advertising van, so that really there is little inducement to attempt to re-establish the old style and type once so much valued in this country by both breeder and user.

Pigs.—For the best Berkshire boars and sows of different ages the competition was good, and the prizes were taken by Mr. E. Tombs, Bampton, Oxon; Mr. C. E. Duckering, Kirton, Lindsey; Mr. H. Humphrey, Shrivvenham; Mr. Russell, Swanwick College Farm, Cirencester; and the Messrs. Hewer of Sevenhampton, Wilts. Having given the names of the prizewinners it will enable parties to know of whom to obtain the best stock. This breed is well known to be adapted for the production of the best bacon, as they afford a good proportion of fat and lean meat; they are also very prolific, and are usually good mothers. The large white breed were not represented on this occasion, which we regret, because we know they are so valuable for crossing with the Berkshire; in fact, we think this cross is more profitable than any pure breed, as they come earlier to maturity by making the best quarter pork at the earliest age. For the best pair of sows of a small white breed, only one entry by Her Majesty the Queen. These were, however, very choice animals, and bred at the Shaw Farm, Windsor. For Sussex pigs the prizewinners being Mr. J. Kent, Bognor, Sussex; Messrs. Stanford, Steyning; and Mr. Wheeler, Shepton-on-Stour. Each of these exhibitors entered some capital specimens of this breed, which are much approved in some southern districts. The show of pigs as a whole was adverse in one respect—that is, as breeding stock being too fat, and, in the helpless condition in which they were shown, were for the most part incapable of propagating their species.

WORK ON THE HOME FARM.

Horse Labour.—At intervals when the farm horses are not required in actual cultivation of the land, such as ploughing, harrowing, rolling, &c., chalk and lime may be carted to the farm, the former being placed near to where it will be required in dressing the land, the latter to be stored in a dry outbuilding ready for use during the autumn. After the field hay has been cleared it will be found in various instances, especially on the mixed soils in the enclosed districts, that there will be some couch grass in the Clover lea. Whenever this is found to be the case—and it is unfortunately but too common, in consequence of several difficult seasons when the land could not be effectively fallowed—the lea land should be rather ploughed and then scarified with Coleman's implement, not using the shares but the points only, in order that the land may be laid up rough, and in this way the white roots of the couch will be lifted out of the land to be dealt with and worked out by dragging, harrowing, rolling, &c., instead of being partially left in the land by the cutting action of the shares. After the land has been cleared of couch, which it may be by several scarifyings, the dung intended for the Wheat crop may then be laid out and spread, and about the last week in August or the first week in September the land may be ploughed and pressed, and thus remain to get mellow and stale, and only be worked down fine just before the act of drilling the seed for Wheat. Any light work, such as second or third scarifying, may be done with the strong iron-framed horse hoe, using the points or tines only, and drawn only by one horse, and in this way any remaining couch roots will be effectually removed at little cost, because the one horse will do 2½ acres per day, whereas Coleman's heavy implement would scarcely do 4 acres per day with three horses attached. It is, however, very important that the animals for single horse labour should be powerful, active, and in good condition; the strongest horse hoe should be obtained, so that it may be available not only for forcing root crops, but with appropriate shares, knives, and tines be capable of hoeing corn crops and doing scarifying work as well.

Hand Labour.—The hay in the backward districts and in the irrigated meadows everywhere will still be in the process of cutting, making, carting, stacking, &c. Great delay has taken place for some time past owing to showery weather, and considerable injury has been done to the hay crop. We therefore recommend in order to restore to some extent the lost condition and feeding value, the use and application at the time of stacking of certain spice or flavouring materials. The men will also be employed in tucking and trimming the hay stacks, and in drawing and piling straw for thatching, &c.

Turnip hoeing will be continued, and in some districts where labour is scarce we find that the Swedes, Turnips, &c., have made such rapid growth lately, and are so thick in the lines, that it will be difficult to complete the hand-hoeing in a proper manner if the work is delayed. We therefore recommend wherever the plants are thick in the rows that, instead of dragging or harrowing the lines across, to work the horse hoe across the lines with three cutting shares—that is to say, by reversing the outer shares or knives. The plants will then be cut out into bunches at the required distance, or indeed any distance, by a correct adjustment of the shares. This plan has the advantage of moving the ground as well as setting out the plants in bunches at intervals, and maintains them in growing condition until they can be singled out in a regular manner by hand-hoeing. Sowing common Turnips will still be continued with the prospect of a useful crop. Planting or ploughing-in plants of the Thousand-headed Kale may be continued, or in fact various kinds of Cabbage or Broccoli may be planted during the month of July with a fair prospect of obtaining a useful crop, especially of the small Drumhead Savoy, for late spring use. At this time, too, may be sown the new variety of Early Horn Carrot seed as sold by the principal seedsmen; these roots will be ready for sale in bunches in the vegetable markets for consumption in the autumn and early winter months, and will pay well where the land is within reach of any large town. The early fairs for sheep are now taking place, particularly of the Hampshire or West Country Downs, and if the ewes are purchased now they will offer to the ram almost immediately on their arrival at their new home. They should receive a generous diet, and particularly cake or cracked Beans at the time they are feeding upon the Clover or Saintfoin leaves, with a fold of Rape at night time; we consider Rape as the best vegetable food to induce the ewes to offer early to the ram. As fast as the ewes have been served they may be drafted and kept until lambing time without cake or any food costing extra money. The dairy cows will now in some instances be on the wane as to the quantity of milk given unless food besides the pasture grass is supplemented, especially where the grassland is inferior in quality of herbage. Various kinds of green fodder will still be available for the purpose when its use has been anticipated, such as Clover, Lucerne, spring-sown Trifolium, late-sown summer Vetches with tall Rape, &c.

ROUP IN FOWLS.

ROUP is the most troublesome, offensive, and with the single exception of cholera, the most fatal disease that the poultry breeder has to fight against. It generally commences with hoarseness and sneezing, and while in this stage may be easily cured. In the second stage of the disease the eyes become swollen, and nose and eyes discharge a thin watery substance that thickens and becomes very offensive as the disease progresses; ulcers form in the mouth and throat and around the eyes, the head swells, one or both eyes are closed, the comb turns black, the fowl loses its appetite, wastes away and dies.

Roup never comes without a cause, and the cause may be found in damp, filthy, ill-ventilated houses, wet swampy yards, impure drinking water, food that is insufficient in quantity and quality, crowding too many fowls in one building without paying the slightest attention to the sanitary regulations necessary to keep them in good health.

Roup is contagious, and when it once gets started in a district the premises of the most careful poultry breeders are liable to be invaded; but if you permit none of the causes mentioned to exist around your own premises, and provide dry well ventilated houses, so arranged that the fowls will not be exposed to draughts, it will go a long way towards preventing this insidious disease from getting a hold among your fowls.

The fact that fowls sometimes get along amid the filthiest surroundings with no attacks from roup, shows that filth and this disease are not inseparably connected. Roup in poultry is like diphtheria in the human subject. It is a disease as different from all other diseases as Wheat is from Oats, and, like Wheat or other grain, must spring from seed. The filthiest drains, cess-pools, or streets near human habitations may not cause diphtheria. Before this disease appears in a locality the filthy districts and the clean ones are alike exempt, but after it appears the places having the worst surroundings offer it the most congenial home, and it is apt to come there soonest, stay longest, and show the most severity at such places. But the cleanest, neatest families are not entirely exempt from diphtheria either. Just so when roup is not epidemic, the fowls in the foulest poultry houses escape its ravages; but when it is prevalent in a country it thrives and shows the most malignant form in damp dirty fowl-quarters.

When the roup makes its appearance among fowls, separate the sick from the well fowls at once, and thoroughly cleanse and disinfect the house. Whitewash the inside of the house, clean and disinfect the feed boxes and drinking vessels, and afterwards fumigate the house with sulphur.

Give the well fowls a tablespoonful of castor oil apiece, and

fumigate them by throwing a handful of sulphur on a pan of live coals placed in the house after the fowls have gone to roost. Give sulphur, pulverised charcoal, and pepper in the food once a day until the disease disappears from your premises.

If the sick fowls have not advanced beyond the first stage of the disease give them a large dose of castor oil, fumigate thoroughly with sulphur, feed only cooked food seasoned, and in addition give three drops daily of a solution of carbolic acid and water—sixty drops of water to one drop of the acid forms a solution. In mild cases this course of treatment will cure in less than a week.

After the disease has progressed so far that the head and eyes have become swollen, the matter from the nostrils offensive, and the mouth filled with ulcers, kill the worst cases and bury them. Give the others the same treatment recommended for the mild cases, except that chlorate of potash may be given in the drinking water once a day, and pulverised chlorate of potash, or burnt alum applied twice a day to the ulcers in the mouth and throat. Do not return the fowls that have been cured to the general poultry house for at least a week after recovery.—(*Prairie Farmer*.)

TOY PIGEONS—THE NUN.

THERE are few prettier Toy Pigeons than the Nun. In the old Pigeon books it always had a prominent place, and is well described in the "Dovecote and Aviary," a charming book of the days of our childhood, but now rather behind the times, since Pigeon fancying has become quite a scientific pursuit. Nuns were formerly far more popular among fanciers than they are at present; this change is, we fear, due to dishonest practices which the mania for exhibitions has stimulated. The variety is one which it is not easy to breed to anything like perfection, but which unfortunately is easily "improved" by trimming. The result of this is that unscrupulous exhibitors have so often carried off prizes with trimmed birds that honest fanciers have become disgusted, and have either given up the breed or kept their birds at home, and committees of shows seldom give special classes for it. The Nun is not a bird of many points or those very difficult of description, but its markings require to be very precise, not only for correctness from a fancier's point of view, but even to satisfy an ordinary eye for beauty. It is a small Pigeon with small straight (*i.e.*, not "downfaced") beak, and has the feathers all round the back of the head turned upwards, so as to form a cup or shell extending almost from ear to ear. The general plumage of the bird is white with the exception of the tail, the flight feathers, and the head, which are of some one colour, hence doubtless its name, the coloured or black head giving the idea of a Nun's veil. The chief merit of a good specimen is the precision of the head and wing markings.

1, The head should all be coloured within the shell, while the curling feathers of the shell itself should be white; the coloured part should extend downwards from the extremities of the shell in a nice curve and form a well-rounded semicircle on the breast. The difficulty is of course to get these peculiar markings clear and defined; in the shell the coloured feathers are apt to extend backwards, and on the other hand white ones often appear on the cap of the head itself. It is not difficult to see that a little plucking of these, which it is almost impossible to discover, may make the greatest difference in the appearance of the bird. On the breast, again, the semicircle is often ill-defined or misshapen, and the same process will make it perfect, or as fanciers call it "clean cut."

2, As to the flights. The old books give the proper number of those that should be coloured as six; of late several more have found favour with judges. Our idea is that eight or nine give the bird the prettiest appearance, causing the white part of the wing to look nicely rounded off. If possible there should be the same number on both sides. A bird which has this perfection is very valuable.

The eye of the Nun should be "pearl"—*i.e.*, the iris of a very pale pink. The colour of the beak varies, Nuns with black markings having dark, those of all other colours pink beaks. The colours of the markings are black, red, yellow, and blue, and they are called black, red, yellow, and blue "headed," according to their colour. Blacks are by far the most numerous, and certainly the contrast between their general plumage and their markings is very pretty. Good reds and yellows are rarely seen; in English lofts blues are almost extinct. We have seen them, and much admired the softness of their appearance, especially when mixed with the other varieties. The German fanciers occasionally send over Nuns with markings reversed—*i.e.*, the body black or coloured, the head, flights, and tail white. Such are no novelty, for Temminek says (we quote the translation of the "Dovecote and Aviary,") "the most beautiful specimens are those which are

black, but have the quill feathers and the head white. They are called Nonnains-Maurins."

We have found Nuns extremely prolific and excellent nurses. They are active birds and attractive in flight, and to be thoroughly appreciated should have their liberty. We have noticed a peculiarity mentioned by the author of the "Dovecote and Aviary," that when newly hatched the young of the black-headed variety have feet and bills quite dark. From our observations on the difficulty of breeding very perfect specimens it may easily be conjectured that a genuinely nearly perfect Nun is a valuable bird, while from their great prolificacy faulty ones are almost valueless. A young fancier need hardly be warned that birds which at a show seem nearly faultless are not always in reality so, and that unless their exhibitor is well known should not hastily be purchased. We wish some enthusiastic amateurs would take up the breed and improve it in accuracy of markings, as it certainly might be improved by careful selection. The various peristeronic societies, too, in some of which the members bind themselves to show only *bonâ fide* untrimmed birds, might well give more encouragement to it.—C.

VARIETIES.

MR. O. E. CRESSWELL requests us to inform the members of the Poultry Club that he has returned from Sicily to Morney Cross, near Hereford, and can again attend to the business of the Club.

— **POULTRY SHOWS.**—We receive almost daily schedules of more summer shows to be held shortly. The Neath Show of Flowers, Fruit, Dogs, Poultry, and Pigeons is fixed for August 5th. The Poultry and Pigeon classes of the Swansea Show to be held on August 25th and 26th are good. The proportions of the Show of the "Royal Manchester, Liverpool, and North Lancashire Agricultural Society," to be held at Crewe on September 2nd to 6th, are very large.

— **FOOD OF SWANS.**—"H. F." tells us their favourite food is the American Pondweed and insects. There is little doubt but that they eat the ova of fish, but they will not eat fish, excepting it might be as soon as the ova hatches, certainly not when larger.

— **BRITISH BEE-KEEPERS' ASSOCIATION.**—The following are the arrangements made for the South Kensington Show:—Tuesday, July 27th, four o'clock P.M., quarterly Committee Meeting, at which the representatives of affiliated associations are entitled to attend. Special subject for consideration—"Suggested rules and regulations for county associations affiliated with the central Society." Six o'clock P.M., Conversazione. Subject for discussion—"The relations of bees to flowering plants," to be introduced by Frank R. Cheshire, Esq., of Avenue House, Acton. Wednesday, July 28th—General Meeting of the members of the Association at 5.30 P.M.; chair to be taken by the President, the Baroness Burdett-Coutts. Thursday, July 29th—Distribution of prizes by the Lady Aberdare at 5.30 P.M. All the above meetings will take place in the large conservatory adjoining the Show. On Tuesday, July 27th, the Show will open at twelve o'clock noon; on other days at 10 A.M. The Show will remain open on Friday and Saturday, July 30th and 31st, and on Bank Holiday, Monday, August 2nd. Members attending the Show will be required to bring their tickets of membership, which have been forwarded to all those who have paid their subscriptions for the current year, otherwise they will have to pay for admission to the gardens.

— **FEEDING MILCH COWS.**—An American dairyman answers the question "How shall we get the most milk from a cow with the least expense?" by stating:—Give the cows good pasturage and plenty of good water, with food composed of two parts of shorts and one part of corn meal given morning and evening, two quarts each time. Treat the cows gently, and then if they do not give good supplies of milk reject them and get cows that will. Too many cows are kept by milk-producers that do not pay for keeping. Let such be turned off for beef, and fill their places with such as have good milk-producing qualities. Good cows and good feed, with care and kind treatment, will lead to the answer of the above question.

— **USES OF THE POTATO.**—In France the farina is largely used for culinary purposes. The famous gravies, sauces, and soups of France are largely indebted for their excellence to that source, and the bread and pastry equally so, while a deal of the so-called cognac

imported into England from France is distilled from the Potato. Throughout Germany the same uses are common. In Poland the manufacture of spirits from the Potato is a most extensive trade. "Stettin brandy," well known in commerce, is largely imported into England, and is sent from thence to many parts of our foreign possessions as the produce of the Grape, and is placed on many a table of England as the same; while the fair ladies of America perfume themselves with the spirit of Potato under the designation of eau de Cologne. But there are other uses which this esculent is turned to abroad. After extracting the farina, the pulp is manufactured into ornamental articles, such as picture frames, snuff boxes, and several descriptions of toys, and the water that runs from it in the process of manufacture is a most valuable scourer.

— **BEE-KEEPING IN PARIS.**—It is not generally known that among the industries of Paris the keeping of bees is one that is much practised, and frequent complaints have been made to the police about the nuisance this occasioned. One inhabitant alone in the 19th Arrondissement keeps from eight to nine hundred hives, and there are a great number to be found in the 13th Arrondissement, near the goods station at Ivry. Valuable as is the possession of bees to the owners, there is no question but that they do a great deal of damage in various directions. At the Say sugar refinery, for instance, it is calculated that the damage amounts to 25,000*f.* a year, for a whole jarful of syrup will be completely emptied in less than a couple of hours, and two or three bushels of bees are taken or destroyed within the day. The workmen, who are obliged to follow their occupation bare to the waist, suffer terribly from these little pests, and frequently get badly stung.—(*Leeds Mercury.*)

PREVENTING EXCESSIVE SWARMING.

SINCE I last wrote I am happy to say that my method of management so as to prevent excessive swarming, as described in the Journal of July 1st, has answered fully up to my hopes. In the particular case detailed at page 20 the "one swarm" mentioned, a natural one, swarmed again on the 29th of June. This was no second swarm, or "cast," in the ordinary course of things, because I had then destroyed all the royal brood. The bees had simply renewed their preparations for swarming by constructing a fresh number of royal cells which were tenanted in the usual way. I had no hive full of brood to give this swarm as before, because I wanted its brood box to help another stock (see below), so I hived them in a large box with glass windows, putting them in the old place, and setting over it the two supers in which they had been working up to the time the swarm issued. It was so huge a swarm that it filled all three boxes from top to bottom. Before returning the supers I extracted about 10 lbs. of beautiful honeycomb from the larger super and 4 lbs. from the smaller, so as to give them more room for work. The bees began at once to work in all three simultaneously, and honeycomb is now sealing fast. I may mention that the original stock out of which the same queen swarmed on the 15th June has not swarmed again as I half feared at the time. It is now quite full of sealed honeycomb, and the bees are working in a sectional super.

Only two other stocks have attempted to swarm in my apiary. One was a sixteen-bar framer, not however fully worked or filled with brood. The bees were found accidentally *en masse* on an espalier on the 26th of June. Not knowing at the time out of which hive they had issued, they were established separately and put in a large box hive in my bee house, otherwise I should have put them in place of the parent hive and so prevented it from further swarming. As it was, the swarm not being a very large one, I had to strengthen it by setting under it the "brood box" above mentioned, taken from the bees which swarmed on the 29th. In the interval the bees had constructed several combs, which they have largely extended since; in fact, as I write, owing to the rapid and continued increase in the population, the large box in which they were hived (now a huge super) is nearly full of comb, while breeding has never ceased for a day since the swarm was established. Weather permitting I hope to have a great harvest from this swarm, which indeed may virtually be considered a non-swarmed stock.

To return to the parent hive. As the bees attempted to swarm again on the 5th July I thought it prudent in view of my absence from home to divide its sixteen-bar frames, making two stocks of it. These are now doing well, one of them actually working in a super. The only other hive in my apiary from which up to the present time (July 15th) a swarm has come is an Abbott-Woodbury. It

issued first on the 25th of June, and was returned after excision of all royal cells. It swarmed again on the 5th of July, having taken only ten days to reconstruct royal cells and repopulate them. In the interval, however, the bees yielded me $11\frac{1}{2}$ lbs. of rich honey in a doubled Lee's Crystal Palace super. To effectually prevent any further attempt at swarming I set over them a full-sized Woodbury without the intervention of any top or adapting board. Into this Woodbury (super) I also put one of their own bar-frames full of brood. Here they are doing splendidly, having the full benefit of their enormous population as if they had never attempted to swarm. The bar-frames in this super have guide combs of artificial fabric, more or less worked upon during the temporary occupation of this Woodbury by an earlier swarm.

Anyone who has thought it worth while to follow with attention the foregoing somewhat complicated account of my various bee operations this summer will see that my object has been fairly well attained. Swarming has been effectually checked, and the consequent weakening of the various hives by over-division prevented. Under ordinary treatment I should probably have had by this time over twenty-eight separate colonies, with a comparatively small number of bees at liberty to gather honey; whereas including the artificial swarms which I described in a former Journal, the sum total is fourteen stocks with an overflowing population of honey-gatherers in most of them. I say nothing of the immense saving of labour and watching which has attended this treatment of my apiary. My bees, too, have been singularly quiet and peaceable.—B. & W.

ARTIFICIAL COMB FOUNDATION.

I AM sorry that my remarks on this subject have aggrieved Mr. Raitt. In writing I endeavour to avoid the use of names, personalities, or remarks likely to cause pain to others. If I fail in my endeavour I hurt myself most. The question of artificial comb foundations sagging when used is one of long standing and has been considered a great difficulty. Laudable efforts have been made to overcome it. Even Mr. Raitt acknowledges that he has "tried strengthening materials, and has embedded in the heart of sheets threads of silk and raffia, and strips of parchment and tinfoil, with satisfactory results." I obtained some for experiment in supering, and was told to use it in small pieces, otherwise I should fail. Though quite ignorant on the subject I fancied that if useful in small pieces it would be more useful if used in large pieces, and believed that bar-frames could be entirely and advantageously filled with the foundations before swarms were hived amongst them. My experiment was a simple one and honestly recorded. My super was wedge-shaped, all of wood except the top, which was glass. The foundation sheets were cut to fit the box, and put in resting on the sides and bottom. The bees very soon fastened them to the bottom and sides. The cells were elongated and securely fastened to the bottom and half filled with honey. A broad foundation was laid, and everything seemed promising. Sure enough I was in love with both the wedge-shaped box and foundations, and the bees seemed as proud of them as I was. Thousands came up to finish the work so well begun. Honey shined in the cells. Some combs at the outside of the box reached the glass lid and were fastened to it. In the middle of the box the combs began to bend like blades of corn and curve by their own weight; in fact they bent over against one another, and the bees cemented them. And here let me say I am, and have been all my life, naturally inquisitive—always tracing cause and effect, and wanting good reasons—easy work and short cuts. In the case in question I want to know what made the combs to bend at the top of the super in the middle of the box. I openly and frankly say that I am ignorant, and ask others to tell me. I have as yet had no answer to the question. Mr. Raitt's illustration about a rope does not come near the subject. The bending combs were strong and broad enough at the bottom and for 3 inches upwards, and stood erect; above, they bent over and hung down like a loose line between two clothes posts. This is the kind of sagging which has engaged the attention of Mr. Raitt and other clever bee-keepers for years. Natural combs built upwards or downwards do not sag, and hence the question, Why do artificial foundations sag? I shall be thankful if Mr. Raitt or any other writer will explain it.

The simple experiment that I made has fully convinced me that the wedge-shape super is the best for the use of artificial comb foundations. The foundations resting on the sides of the super are held in position till the bees fasten them better. If the pieces used had been large enough to reach the lids the bees, doubtless, would have fastened them to the lids, and thus the sagging would have been prevented. The sagging was not observed, or did not begin till the crowd of workers in the supers increased the heat con-

siderably. The sagging took place in the centre where heat was greatest; and though the idea of imperfect materials was suggested to my mind, I could not entertain the idea of my friend using imperfect or impure materials wittingly. I know Mr. Raitt to be a thoroughly honest man, but adulteration of almost all kinds of manufactured materials is so common and general, that I should not have thought less of Mr. Raitt or any other manufacturer if he had been misled in the purchase of wax not altogether genuine. I get 4d. per lb. more for my wax than the retail price of dealers whose wax looks quite as good and pure as mine. But now Mr. Raitt assures us his foundations are made of pure wax, and I believe him.

I believe that the foundations will be largely used in future, especially in the bar-frame school of apiarians, and that large pieces of the sheets will be successfully used without the supports so much sought after, and therefore I fancy that the question of the cause of sagging deserves more attention than the by-play of boys climbing up a rope. That the heat of the bees caused the combs in my case to soften and bend at their tops I verily believe, but why the heat did so is a mystery to—A. PETTIGREW.

OUR LETTER BOX.

Dead Grubs in Hive (N. McA.).—The grubs arrived this time safe enough, but were all in so advanced a stage of corruption, minute flies actually issuing from them, that it was impossible to form any conclusion as to the cause of death. If you send some to Mr. Frank Cheshire, Acton, W., in a less decomposed state, he would probably tell you whether the disease which seems to have attacked your apiary is foul brood or not. It has never yet attacked our hives.

REMARKS.

11th.—Dull morning, heavy shower 10.30 A.M. and 1 P.M., fine rest of the day.
 12th.—Very bright morning, overcast afternoon, fine evening.
 13th.—Bright and fine before noon, afternoon overcast, fine evening.
 14th.—Dull hazy morn, violent thunderstorm 0.45 to 5.55 P.M., thunder very loud, fine afternoon and evening.
 15th.—Excessively damp hazy morn, rain between 9 and 10 A.M., heavy clouds all day, particularly between 7 and 8 P.M., sunshine for short time in afternoon; clear night.
 16th.—Damp sultry day but no rain, thunder 5.47 P.M. till 6.15 P.M.; fair evening.
 17th.—More or less cloud all day and very oppressive, rain at 10 P.M.
 Temperature rather above the average, but cloudy and no extreme heat, much thunder and occasional heavy showers.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 21.

THE market continues well supplied with all classes of goods, prices generally being lower, the state of business remaining much the same as last week.

VEGETABLES FOR AUTUMN SOWING.

A FULL supply of vegetables as early in the season as possible is the object which all good cultivators seek to obtain, and I question if in the whole routine of gardening they can devote their attention to any object of more importance. Now that we cannot depend on having spring weather until the end of May, too much care cannot be bestowed on all crops which can be sown in the autumn to grow throughout the winter and give us the earliest produce attainable. First amongst these crops we will place

CABBAGE.

A good supply of fine Cabbages all the year round is what every gardener should provide. In summer, autumn, and winter they are in constant demand, but if there is one period of the season more than another when they are most valued it is in April and May. At that time the demand is not confined to large gardens or servants' halls, but every person who possesses a garden must have spring Cabbages, and the earlier and better they have them the more gratifying is the result. Could we depend on the winters and springs being all alike it might be told to a day when to sow Cabbage seed to have the produce ready for use at any given time. As it is, however, little can be said about this, as seed sown from the middle to the end of July might produce plants which under the influences of a mild winter would all produce flower stems in March or April, while under different weather the plants might produce fine heads in April or May. For these reasons the best way is to sow the seed at two or three different times. I prefer sowing three times; first about the 12th of July, second about the last of that month, and again about the end of the second week in August. This plan is worth adopting in all parts of the country. The seed may be sown in large or small quantities according to the demand. It may be sown broadcast, not too thickly or too deeply. The soil should be good but not too rich for the seed bed, moderate growth being more desirable than too many soft leaves, as the plants in this state receive a check in transplanting and do not endure severe weather well. When the soil is very dry at the time of sowing it should be thoroughly watered after the seed is sown, but avoid covering with a mat or anything of the kind, which only renders the young plants tender—a condition always to be avoided with autumn or winter Cabbages. Remove any weeds that spring up amongst the young plants, and if by any chance the seed has been sown too thickly remove the worst of the plants, and give those intended for the crop every chance of

becoming strong and healthy. These remarks should be borne in mind in dealing with seed sown at any time. As the young plants are coming forward a suitable quarter must be selected in which to finally plant them.

"Plant them after Onions" is the proverbial advice, but I fear that for the last season or two Onions in many cases have not been ripe and cleared off the ground sufficiently early to allow the Cabbages to follow them. When this occurs with us we plant them after midseason Potatoes, and find them succeed fairly well. When the ground is moderately rich no manure should be added, and the soil merely levelled down with the spade answers better than digging for these Cabbages. Poor soil must, however, be improved, and the material supplied should be either fresh cow or stable manure. The date on which to plant out must be determined by the size of the plants. When they are about 6 inches high and have from eight to ten good leaves they may be safely transferred to their permanent quarters. Only the largest and best plants should be taken at first; and if it is intended to devote only one plot of ground to Cabbages, plants from each sowing should be placed in it. This, as before indicated, will have the effect of securing good spring Cabbages under any circumstances. A distance of 18 inches each way is suitable for most varieties. Plants not required for planting should be left in the seed bed, or be lifted and dibbled into a bed about 3 inches apart, as these are very useful for planting-out in spring or filling-up any blanks which may occur in those planted in autumn. Supposing the planting-out to be any time during September they will have gained a fair size by the end of October, and it is best to draw a little soil to their stems then, as keeping them firm in their places during the winter is much better than allowing them to be blown about.

Respecting varieties there are many to choose from. Early York and Enfield Market were two standard varieties for sowing at the present time for many years, but these have now been greatly improved upon. The main object to aim at is to obtain very dwarf, compact-growing, free-hearting varieties, and all these qualities are largely possessed by Carters' Heartwell Early Marrow and Suttons' Imperial, which are both well-known thoroughly good varieties. During the spring of this year I received a little seed from Edinburgh of a new variety named "Redbraes," and this has proved so far most distinct and excellent. Its leaves are frilled round the margin, and it grows very compact. The heads are about 10 inches in diameter at the base, and taper off to a small point, the whole plant being about a foot in height. Large-heading sorts should not be grown, as they are neither profitable as a crop nor good in quality.

TURNIPS.

A good supply of these during the winter is always valued. To have good fresh roots from November onwards the seed should be sown during the first week in August. Chirk Castle is one of the best varieties to sow, as it stands the winter well. The golden varieties are also hardy, but their colour is seldom liked, and for this reason many cannot grow them. They do well on ground just cleared of Peas or Potatoes, but the soil should neither be very loose or very rich, or long small "bulbs" will be produced. Ground in which Turnips would become tough before they were half grown in the months of June, July, and August, will generally produce a satisfactory crop during October and November. Where the space is small the

rows may be placed 15 inches apart, but 18 inches or more is better. If the seed is good it cannot be sown too thinly, and the plants cannot be thinned-out too early, as short stems from the first is a sure foundation for good, healthy, well-shaped roots. Fly is not troublesome now, and at the first thinning the plants may be left 3 inches apart. In a week or two afterwards every other one may be taken out, and in the end they may be left about 12 inches asunder. This latter distance is not too much in shady or very rich ground. Like Cabbage the seed may be sown at two or three different times, from the first to the last of August.

SPINACH.

Of all winter vegetables this is one of the most useful. Where a variety of vegetables have to be supplied it is quite indispensable. There are only two varieties of Spinach really worth growing, the Round-seeded and the Prickly-seeded. The former is the best for summer use, and the latter should be sown for winter and spring use. The seed should be sown at intervals of fifteen or eighteen days during August and September. That sown in August will give a supply previous to the new year, and the later-sown will come in during spring. Moderately rich ground and an open dry position are advantages in the culture of Spinach. We generally sow it in rows 18 inches apart. When ground is scarce we have sown it between the rows of autumn-planted Cabbages. The seed should be sown very thinly, about $1\frac{1}{2}$ inch below the surface, and as soon as the plants begin to meet in the rows they must be thinned-out to 6 inches or more apart. In severe weather a little bracken or straw thrown over them will afford a useful protection.

ONIONS.

Those sown at the present time are mostly of the Roeca and Tripoli type. They are grown for two purposes—viz., drawing while young for salads, and growing on to a large size for spring use in the kitchen. When grown to be drawn in a small state it is not of much consequence when they are sown, but when they are intended to be grown to maturity more care must be taken with them. When sown too early, and if they become very large in autumn, they generally flower in spring without “bulbing.” As a rule we find them best when they are only about 2 or not more than 3 inches high in February. To have them like this then we sow the seed about the second week in September. In some districts it might be sown earlier, and in others a little later; but in this, as with all other precarious crops, it is best to sow two or three times. Autumn Onions should be sown on deeply-dug and well-manured soil in an open situation. Beds may be formed from 3 feet to 5 feet wide, or the seed may be sown in successional rows. From 10 to 15 inches should be the distance between the rows. If any worms or grubs are suspected to be in the soil a heavy sprinkling of soot or a light coating of salt should be dug-in with the manure, as it is very unsatisfactory to see Onions killed before they are half grown. The seed should be sown thinly, the young plants not being thinned until February or March, when those drawn out may be planted in another piece of ground to form a crop. When wanted as salad, however, some may be drawn during any part of the winter, leaving sufficient in the ground for a crop. The White Naples comes into use earlier in spring than the Roecas, but for size and keeping well the latter are preferred.

LETTUCES.

These when they can be kept fresh and healthy are much valued in winter, and to have them good at that time the seed should be sown early in August, as the plants must become large before the end of October, for they will grow little afterwards. The Black-seeded Bath Cos and All the Year Round Cabbage are two good varieties to sow now. We seldom sow the seed where the plants are to remain, but prefer raising the plants in small beds. The soil in which they are planted should be moderately rich, and the situation should be warm and sheltered. It is generally on south borders and near the bases of walls that we plant our Lettuces after this time. Nine inches apart each way is a good distance to have them. Should the weather be moist at the time of planting a sharp look-out must be kept for snails. Later batches of seed may be sown

at the end of August, and again about the middle of September. To supply young plants from the seed bed early in spring as a first crop “All the Year Round” is a fine variety.

ENDIVE.

This is treated in all respects like the Lettuce, but the last seed is sown not later than the beginning of August. The plants from this sowing give a supply of heads during December, January, and February; late plants intended to come in after that time only run to seed before they are large enough for use, and are therefore not worth growing. The French Moss Curled and Green Curled Winter are two old varieties not yet surpassed.

RADISH.

There are many good spring and summer Radishes, but the winter varieties may be confined to two—viz., Black Spanish and the China Rose, oval-shaped. During August and the early part of September two sowings may be made out of doors in a sunny sheltered position, but during the latter part of September the seed must be sown in frames if Radishes are wanted at Christmas and after that. In all cases the seed must be sown very thinly, as it is only by admitting plenty of light and air to the roots that they can be induced to swell. The soil should also be very firm and not very rich. In winter Radishes keep a long time fit for use after they are fully grown; they must, however, be allowed to remain in the ground, and be protected in very cold or wet weather.

CAULIFLOWER.

The cultivation of this need not be entered into at the present time, but it may be useful to remark that to have plants to stand the winter, and be ready to plant out the first opportunity in spring, the seed should be sown from the middle to the end of August. Early London and anybody's Extra Early may be usefully sown at the same time. The seed may be sown inside a frame on any south border, or in a small patch to be covered with a frame when severe weather comes. Thinly grown plants which have never been “coddled” in any way are those which turn out most satisfactory in spring.—J. MUIR.

COLEUSES.

VARIETIES of these plants have increased so rapidly of late, that persons desirous of growing a limited number must be considerably perplexed if they have no other alternative than nursery-men's catalogues to guide them in their choice. Captain Aubrey Patton, however, has come to the rescue by exhibiting the greatest number of varieties that has ever been placed before the public in one group, and has consequently afforded an excellent opportunity for making a selection of those sorts that appear to be the best worth cultivating. Out of 150 varieties arranged at South Kensington on the occasion of the evening fête on the 21st inst., nearly 130 were placed in commerce within the past two years, indeed many of them were new varieties of the present season. Some of the plants were therefore necessarily small, having been struck from very small cuttings in June, and none of them were propagated before May of the present year. A few of the larger plants were 3 feet high and the same in diameter, ranging downwards to a sixth of that size. Several of the forms are certainly not beautiful; they possess coarseness without colour. The leaves of others are so much cut, so deeply lobed, as to give the plants almost a ragged appearance, while some of the pale-foliaged varieties, almost albinos and destitute of chlorophyll, are evidently bad growers, and unless a Coleus grows freely it is scarcely worth cultivating. Those that are free in growth, distinct, and bright in colour, and there are many of them, are useful for the decoration of conservatories in summer and stoves in winter and early spring. They are most easily cultivated and seldom troubled with insects unless mealy bug prevails, and if this once affects them, which it is very liable to do, it is no easy task to eradicate it. The following are some of the most striking varieties which were included in the group in question.

Dark Varieties.—The finest of these is undoubtedly Allen Chandler, sent out by Messrs. Carter & Co. It is a stately plant; leaves 7 inches long without the footstalk, and 5 inches wide, of a thick velvety texture suffused with magenta crimson. Both under sunlight and gaslight it is very brilliant. It showed to great disadvantage when submitted to the Floral Committee in the dull Council-room on the 13th inst., otherwise it would probably have

had a first-class certificate; it is certain this honour has been awarded to varieties less distinct and attractive. Captain Patton esteems it the finest variety in his possession, and well grown it would make a handsome and imposing pyramid; for the bush form of culture it is not so well adapted. Royal Purple (Bull) is perhaps the darkest of all, and of good habit; will make either a fine pyramid or bush, and "tells well" amongst the lighter colours. George Simpson, a celebrated variety raised by Mr. King and distributed by Messrs. Veitch, is very rich, glowing and effective, with yellow teeth; one of the best. Flambeau is of the type of Allen Chandler, deep bronze green with crimson veins. Turban is also of much the same ground colour, but spotted as well as veined with magenta; distinct and fine. Chelsea Beauty is the finest of Mr. Bull's last batch. The colour is bright velvety crimson with pale crimson veins and very prominent pale yellow teeth; fine. Victory is good, as also is the better known Duchess of Teck. Amazement, though less highly coloured, is distinct, almost grotesque by its deeply cut leaves, the serratures exceeding an inch in depth. Sensation is an improvement on Kentish Fire, and Sunbeam is a bright and bold variety.

Painted Varieties.—These are effective, being generally free in growth, lively in appearance, and adapted to any form of training. Several rather closely resembled each other, but the following are dissimilar and noteworthy:—Gloire de Monceau, distinct; prevailing colour bright deep green with numerous red veins, and mottled all over with greenish yellow. Mons. F. Henricq, prevailing colour yellow, blotched with pale red, and deeply toothed; Keyser Wilhelm, very sportive, the colour varying almost from black to pale yellow, possibly not a robust grower. Miss Florence, much like Gloire de Monceau. M. Grakchef, peculiar rather than beautiful by its purple teeth. James Barnshaw is quite one of the finest, varied in colour, bright and free. Butterfly is also excellent; Earnest Benary is strong, massive, and telling, as also is M. H. Jamain; while Firefly is gay and cheerful, and will make a fine specimen. Placida, red, yellow, and green, is striking, as also are L. W. Baxendale, Brookwood, and Minnie Peed; and Distinction attracts notice by its greenish maroon leaves with purple veins and pink centre.

Yellow Varieties.—One of the finest of these is Canary Bird (Carter); it is very bright and of fine habit. MM. Vilmorin and M. E. Pynaert are also extremely effective as associated with the darker forms. Yellow Gem (Bull) must not be omitted from this section. It is highly distinct and dwarf, cream and pale green with a mottled edge much curled and crisped. M. Charles Avril is fine, very pale crimson and yellow.

Pale and Crisped Varieties.—These are mostly dwarf, and some of them are extremely attractive, while others do not appear to grow freely, those with much white in the foliage being prone to decay. Favourite (Bull) is perhaps the best of all, being free, curious, and bright; but about equally worth growing are Novelty, Lovely, Exquisite, Captivation, and Bijou; the colours cream, green, and pink being more or less represented in the foliage.

The above are selected as the most satisfactory varieties in the collection referred to, and well cultivated will not be likely to disappoint the admirers of this free-growing, gay, and extremely diverse genus of ornamental-foliaged plants. There may be others in commerce equally good that Captain Patton did not procure, but he endeavoured to obtain all the best, and spared neither pains nor expense in rendering his collection as complete as possible. It was a fine group and instructive, but would have been more so had the names of the raisers been included on the extremely neat and attractively written labels.—J.

SCOTCH CHAMPION POTATOES DISEASED.

I AM much obliged for your reply to my query about my Potatoes answered to "G. R. B." in the *Journal of Horticulture*, July 8th. The outbreak of the disease is most mysterious, and I am sorry to say is on the increase. Since I wrote to you the disease has spread among the Scotch Champions, and I fear none of them will escape. The Lapstone and Veitch's Ashleaf are also attacked, and a few Myatt's Prolific, but nothing to the extent of the Champions. Snowflake, and a new Potato named Monarch, and Early Vermont are quite healthy and in full flower. Until the last week the weather has been unusually dry. The rainfall for the year is as follows:—January, 0.46; February, 1.87; March, 1.84; April, 1.42; May, 2.03; June, 1.11; to 10th July, 1.04; total, 9.77 inches. Since 10th July there has been heavy rain. The height of this place is 484 feet above the sea, sandstone subsoil coming in places within 18 inches of the surface. The temperature has been lower than average all the spring, but there was an absence of severe frost, and none of the Potatoes were cut down on the hills, while my neighbours in the valley suffered

considerably. I have seen the person from whom I had the Scotch Champions. They came direct from East Lothian, a few miles from Dunbar, where the Potatoes were quite healthy last year. It is very mysterious.—GEO. R. BIGGE.

[This is indeed a mysterious case. The disease of the Scotch Champions, as sent to us, first appears on the lower portion of the stems close to the ground, and even beneath the surface. We have seen the murrain this year attacking the Magnum Bonum and Grampian in a precisely similar manner, which seems to indicate that the disease spores were in the sets, and that they germinate as soon as the conditions of moisture and temperature are suitable, and the fungus spreads upwards; frequently, or perhaps generally, the murrain attacks the tops and travels downwards. But the perplexing part of the question is that the seed Potatoes now diseased were the produce of crops believed to be perfectly free from the murrain last year. Of course the spores of the fungus may have been in the soil, but if so it is singular that it should have attacked these hitherto considered disease-proof varieties first. We extremely regret this occurrence, and can only advocate the removal and burning of the haulm of the late kinds as soon as it is attacked, and the taking-up of the early crops as soon as the tubers attain their full size. If any cultivators can make any more practical and useful suggestions we will readily publish them. We know of no application that will check the disease; even "salus" quite failed to do so when it was tried at Chiswick.—EDS.]

THE ROSE ELECTION.

It is time, perhaps, that the preliminary note of this year's Rose election should be struck. With the consent of the "ruling powers at No. 171," it will be a Rose election "limited." The term will not apply, however, to those who share in the election, but will be limited to Roses having a *Tea* flavour; in fact, unless good cause is shown to the contrary, it will be an election of Teas and Noisettes only. For two years I have been asked to undertake this.

As Teas are general favourites where they will grow, and seeing that vigour and ability to resist wintry blasts are very essential requisites to success, it does not seem to me advisable to make the election take an "exhibition" form, though doubtless many will frame their opinions by that test. I propose to divide it into twenty-four and thirty-six varieties, using all the replies in the twenty-four, and making a summary of the thirty-six varieties separately. It will be interesting to compare both tables, and seeing how far the smaller growers agree in their opinions with those who try every variety. The question, then, will be—

Name the best six Teas or Noisette Roses for general purposes, the second best six, the next best twelve.

Those who choose can add a third twelve, making thirty-six in all.

I shall be glad to have replies by the last day of August.—JOSEPH HINTON, *Warminster*.

EVENING FÊTE AT SOUTH KENSINGTON.

THE Royal Horticultural Society held its annual evening fête at South Kensington on Wednesday the 21st inst., and being favoured with fine weather after a few showers in the early part of the evening, it proved highly successful, and a very large and distinguished company assembled to enjoy the numerous attractions provided. The east and west quadrants were occupied by numerous collections of plants, which appeared to excellent advantage beneath the electric light. Of the plants thus contributed a large proportion were from the Society's garden at Chiswick, one group of Tuberous Begonias being particularly attractive. An extensive and imposing collection of plants were staged by Captain Patton in the east quadrant, comprising 150 varieties of Coleuses, some of them very handsome, arranged with Palms, Lilies, and miscellaneous fine-foliage plants. Another very attractive group was that from H. J. Atkinson, Esq., Gunnersbury House, Acton (gardener, Mr. Hudson), which contained some handsome specimen Ferns, Crotons, Palms, and other plants effectively arranged. Mrs. Hudson contributed an elegant and pleasing example of table decoration, which found many admirers. Nurserymen also exhibited well, one of the principal groups being that from Mr. B. S. Williams, Victoria Nurseries, Upper Holloway, which included a number of choice stove plants; Orchids, Palms, Nepenthes, Ferns, &c., being exceptionally well represented. The General Horticultural Company sent a large and beautiful group of Palms, Ferns, Gloxinias, and others, the central plant being a fine specimen of the beautifully variegated *Phyllanthus nivosus*. Messrs. Osborn & Son, Fulham, had a pleasing arrangement of fine-foliage plants; and Mr. Aldous, South Kensington, exhibited a graceful mode of decorating a fire grate and mantelshelf. Messrs. Dick Radclyffe & Co., High Holborn, contributed a charming arrangement for a grotto; and Mr. Cannell, Swanley, staged a large collection of trusses of Ver-

benas representing more than 150 varieties, very bright and rich in colour.

The grounds were illuminated with Messrs. Siemens' electric light, which proved on this occasion exceptionally brilliant and steady, and upwards of eight thousand coloured lamps, which were arranged spirally up the stems of trees, in festoons from tree to tree, among the branches, and around the fountains, considerable taste being displayed in the arrangement. Coloured fires were employed at intervals, but owing to the stillness of the air the smoke somewhat marred the effect. In the conservatory the Kensington Amateur Choral Society sang an admirable selection of part songs, and on the terrace the bands of the Royal Horse Guards and Life Guards contributed greatly to the pleasure of the visitors. Under the superintendence of the Secretary and members of the Council, Mr. Barron the Superintendent, and Mr. Dick the Assistant Secretary, carried out the arrangements with great efficiency; indeed in every respect this was probably the most successful meeting of the kind ever held by the Society.

GARDENIAS.

PLANTS that have flowered late should be pruned, but not too closely unless they are overgrown, when they may be cut well back, otherwise the mere removal of irregularities of growth is all that is required. The plants should be thoroughly cleaned from mealy bug and scale, as the growth being old will admit of an insecticide being applied at a greater strength than when the shoots are young and soft. A solution of nicotine soap, 6 ozs. to the gallon of water, will destroy both mealy bug and scale, either by dipping the plants or syringing them with the solution at a temperature of 100° to 120°. To be effectual, however, it must be thoroughly done, as partial cleansing only leaves stock to breed, and gives the impression that plants cannot be cleansed of mealy bug when once they are affected. The plants should be encouraged to make growth by plenty of heat and a moist atmosphere, and when fairly growing should be repotted, merely loosening the sides of the ball and removing any loose soil. Young stock that it is desired to advance quickly should be moved into larger pots, and encouraged at the warmest end of the stove by syringing every evening. *Gardenia florida intermedia* is by far the largest and freest-flowered of the family, and should be grown in quantity.—G. P.

WIRRAL ROSE SHOW.

WILL it not surprise the readers of the Journal to hear that the best Rose Show of the year has been that held by a young Society only two years old, and in a place concerning which the exclamation will be in nine cases out of ten—"Wirral! Wirral! Never heard of such a place!" Not so extensive as that at the Crystal Palace, but certainly as large as that of the National Rose Society at Manchester, and in the quality of the exhibits exceeding it. As the reporter for the Journal was taking notes I shall content myself with a few general observations.

Wirral is the name of the hundred in which Birkenhead is situated, and the Show was held in the archery ground in Birkenhead Park, and in a tent were staged some of the finest stands I have seen this year. When I say that Messrs. Cranston, Paul & Son, Davison, Prince, &c., exhibited amongst the growers for sale, and Messrs. Jowitt and Hawtrey amongst amateurs, it will be readily conceded that the materials for a fine exhibition were not wanting. But how, it will be asked, could such growers be induced to go to so new a Society and so far off? Simply this: Birkenhead possesses a considerable number of Rose-growers, who are also by no means timid men; and believing that what is to be done at all should be done well, they agreed that twenty of them should put down five guineas apiece as a guarantee fund, and, thus securing themselves against possible loss, should offer such prizes as would induce growers from a distance; and having, moreover, a Secretary whose energy belonged to no limited liability, but is untiring, they have attained the proud pre-eminence of holding the best Exhibition of the year, with the one exception of the National. There was but one element of disappointment—the weather, which has proved so treacherous this year and has so defied all forecasts; it was as bad as could be, and I fear the guarantors will have to suffer; but as one of them said, "We shall cheerfully pay up our five guineas and come up again." With such a spirit amongst them it needs no seer to predict a successful time for the Wirral Rose Society.

Although Mr. Cranston was, as he everywhere has been this year, *facile princeps*, yet I should be inclined to give the palm to the box of thirty-six exhibited by Mr. Jowitt, for this was as near perfection as possible. I question very much if he could have picked out such a thirty-six out of his stand of forty-eight with which he won the cup at the Crystal Palace. Some of the blooms, such as A. K. Williams, Beauty of Waltham, Marie Rady, and Charles Lefebvre, were inexpressibly grand. Your reporter will have noticed, I have no doubt, most of the fine blooms, but I cannot pass by the magnificent twelve Marie Radys of Mr. Cranston, or the very nearly equally grand twelve of Marie Baumann of Messrs. F. and A. Dickson & Sons, Chester. I have never seen such a stand of Marie Rady, and it nearly equalled

the splendid twelve Alfred Colomb of Mr. Jowitt shown at Manchester. Amongst local exhibitors Mr. T. B. Hall of Lant Grove, Rock Ferry, had by far the finest collection, winning the first prize for twenty-four blooms, and the National Rose Society's silver medal. I was not surprised at the excellence of the blooms when I saw the splendid growth of his plants. I must add personally it was a visit of great enjoyment. I went to Wirral as a stranger, but was received with the utmost cordiality and kindness, especially by the President, Mr. Hall, and that I look forward with much pleasure to a renewal of an acquaintance so happily begun.—D., Deal.

THIS, the second Show of the Wirral Rose Society, was held on the 24th inst. in Birkenhead Park. Last year the Society held their Exhibition at Bebington, and offered about £30 in prizes. This year they offered a schedule of fifteen classes and gave £105 in prizes. This undoubtedly proved the finest Rose Show of the year, with the exception, perhaps, of the Crystal Palace, but, unfortunately, the weather was most unpropitious. The few days of good weather previous to the Show told considerably upon the blooms, and they were exhibited on the whole in much better condition than those shown at Manchester the previous week; they were indeed of first-class quality both as regards size, freshness, and colour; and light Roses, especially Hybrid Perpetuals, were shown in greater numbers and better condition than we have before seen this season. Messrs. Cranston & Co., Hereford, staged a very fine box of their new Rose Mrs. Jowitt; the colour was very bright and the foliage healthy, clean, and large, not a trace of spot or mildew to be found upon it. The same firm exhibited a magnificent box of Mdle. Marie Rady; and Messrs. James Dickson & Sons, Newton Nurseries, Chester, a fresh and fine stand of Marie Baumann, which the leading rosarians considered had not been shown in such condition this season.

NURSEYMEN'S CLASSES.—For twenty-two varieties, distinct, single trusses, first, Messrs. Cranston & Co., Hereford, with beautiful flowers, and much ahead of any others in this class. Amongst their most noteworthy blooms were Abel Carrière, Marie Baumann, La Duchesse de Morny, very fine; Duke of Wellington, Madame Victor Verdier, Emilie Hausburg, Duc de Rohan, Mrs. Laxton, full and very fine; Dr. Andry, Fisher Holmes, Souvenir de Mons. Paul Neyron, Edouard Pynaert, Reynolds Hole, Dupuy Jamain, Etienne Levet, Jean Liabaud, Mdle. Eugénie Verdier, Exposition de Brie, Catherine Mermet, Mary Pochin, A. K. Williams, Louis Van Houtte, and La France. Second, Messrs. Paul & Sons, Old Nurseries, Cheshunt, with good blooms among others of Mrs. Baker, Sénateur Vaisse, Edouard Dufour, John Stuart Mill, Souvenir d'Elise Vardon, Lord Beaconsfield, Louis Van Houtte, Annie Wood, Miss Poole, Xavier Olibo, Antoine Ducher, Duke of Edinburgh, and Marquis of Salisbury. Third, G. Prince, Oxford, with Marcelin Roda, Catherine Mermet, Duc de Montpensier, Duchesse de Vallombrosa, Perle des Jardins, Annie Wood, Capitaine Christy, Horace Vernet, and Duke of Edinburgh as the leading flowers. Messrs. Francis and Arthur Dickson & Sons were the other exhibitors and staged excellent blooms.

In the class for thirty-six varieties, three blooms of each, there were six entries, and the competition was very close. First, Messrs. Cranston & Co. with Mrs. Jowitt, very fine; Alfred Colomb, Le Havre, Charles Lefebvre, Elie Morel, La France, Capitaine Christy, Baronne de Rothschild, Sénateur Vaisse, Niphetos, Sir Garnet Wolseley, and Catherine Mermet. Second, Messrs. Davison & Co., Hereford, with good blooms of the following—Charles Wood, Beauty of Waltham, John Stuart Mill, Mdle. Marie Rady, Alfred Colomb, Sultan of Zanzibar, and Marguerite Brassac. Equal thirds, Messrs. Paul and Sons and G. Prince, Oxford; the former having good blooms of Prince Arthur, Camille Bernardin, Duc de Rohan, La France, Capitaine Christy, A. K. Williams, Sénateur Vaisse, and Louis Van Houtte; the latter having Perle des Jardins, Annie Wood, La France, Souvenir de Mons. Paul Neyron, Etienne Levet, and Mons. E. Y. Teas in superior condition.

In the open class for thirty-six varieties, single blooms, first, T. Jowitt, Esq., Old Weir, Hereford, with magnificent blooms, including Alfred Colomb, Mons. Noman, Duke of Wellington, Lord Herbert, Beauty of Waltham, Mdle. Marie Rady, La France, Ferdinand de Lesseps, Charles Lefebvre, and Horace Vernet in such condition as is rarely seen. Second, Mr. Griffiths, Hereford, with good blooms of Fisher Holmes, Beauty of Waltham, Alfred Colomb, Sir G. Wolseley, Marie Baumann, Mrs. Laxton, La France, and Comtesse de Serenye. Third, Messrs. James Dickson & Sons, Chester; John Hopper, Xavier Olibo, Beauty of Waltham, Mons. E. Y. Teas, being extremely fine. In the class for twelve blooms of any one Hybrid Perpetual Rose, first, Cranston & Co., with Mdle. Marie Rady above alluded to. Second, James Dickson & Sons with Marie Baumann. Third, G. Prince with Alfred Colomb. Extra prize, T. Jowitt, Esq., with John Stuart Mill. All the stands were splendid.

AMATEURS' CLASSES.—Thirty-six varieties, single blooms. First, T. Jowitt, Esq., with a magnificent stand. The bloom of A. K. Williams was undoubtedly the best in the Show; Mdle. Marie Rady, Sir G. Wolseley, François Michelin, Louis Van Houtte, La Duchesse de Morny, Comtesse de Serenye, Marie Baumann, Madame C. Crapet were also in grand condition. Second, G. P. Hawtrey, Esq., who staged among others splendid blooms of La France, Duke of Edinburgh, Mdle. Marie Rady, Marie Baumann, Thérèse Levet, and Marguerite Brassac. Third, G. H. Berrington, Esq.; Louis Van

Houtte, La France, Sir G. Wolseley, Perle des Jardins, and François Michelin being the finest blooms. Fourth, C. W. Newmann, Esq., Wyncote, Allerton (gardener, Mr. Mease). The finest bloom in this box was Maréchal Niel, and without doubt the finest in the Show of that variety. Sir G. Wolseley and Marie Baumann were also good. The blooms were smaller than those shown by the previous prize-takers, but very good considering the locality in which they were grown. There were seven entries in this class.

For twelve varieties, single blooms, of Teas or Noisettes, Messrs. T. Jowitt and J. P. Hawtreys were each awarded equal first prizes, the former having good fine examples of Niphotos, Alba Rosea, Rubens, and Maréchal Niel; the latter excellent blooms of Caroline Kuster, Catherine Mermet, Souvenir de Mons. Paul Neyron, and Amazon.

Amateurs' classes for Roses grown within the Hundred of Wirral. —For twenty varieties, single blooms, first, T. B. Hall, Esq., whose stand included Eugène Furst, a fine dark flower and much admired; although much resembling Louis Van Houtte, the wood was quite distinct; Etienne Levet, Thomas Mills, Mdle. Marie Finger, and Sénateur Vaise were also good. Second, Mr. Joseph Meyer; Mdle. Marie Rady and Prince Camille de Rohan being the finest blooms. Third, Mr. T. Griffiths with a good stand containing fine blooms of Paul Neyron and Charles Lefebvre. For twelve varieties, single blooms, first, W. Just, Esq. (gardener, Mr. McMaster), with a good stand of blooms which included a very large example of Mdle. Hippolyte Jamain. This bloom was also awarded the prize for the premier Rose. Second, Mr. Hodgson; third, Mr. J. Hargreaves; fourth, Mr. J. T. Raynes. For twelve varieties, single blooms, Messrs. D. Walford, J. Myers, and T. B. Hall, were awarded the prizes in the order named. Six varieties, single blooms, Messrs. Just, Hodgson, Raynes, and Gaman were the prizetakers respectively. For three varieties, single blooms, the awards went to Messrs. Just, Hodgson, and Hargreaves.

MISCELLANEOUS EXHIBITS.—Mr. J. Smith, nurseryman, Cloughton, exhibited a collection of flowering and foliage plants, which occupied one end of the tent. The other end was occupied with plants from Messrs. F. and A. Dickson & Sons, Chester, and Mr. Smith, Dell Nursery, Rock Ferry, both collections including some clean well-grown decorative plants. Messrs. F. and A. Dickson & Sons also exhibited a box of Roses, which included good blooms of Richard Wallace, Alfred Colomb, Duc de Rohan, Horace Vernet, and Jean Liaband; Mr. Griffiths, Hereford, a box of Marie Baumann and of Comtesse de Serenye, the latter being remarkably good. The Committee of Management and Mr. Smith, the Honorary Secretary, laboured assiduously to render the Show a success. New societies, however, do not always adopt the best system of managing the exhibitions in respect of the numbers, prize cards, &c.; but *experientia docet*.

The Judges were the Rev. H. H. D'Ombrian; Messrs. Elliott, Francis, and Prince.

PRIMROSES.

THE common Primrose, when well grown in rich light soil, will in the third year become a large plant and most useful for early spring flowering. Seedling plants will be found near any old clump, and these should now be planted out in the borders. Next year they will form good flowering clumps, producing a dozen flowers or so, and the year following if properly grown they will bear flowers by hundreds. I have counted as many as 350 flowers at one time on a single three-year-old clump of the common yellow Primrose. The coloured varieties of this flower are a so very well worth attention. I have at least fifty well-marked varieties here, varying from the deepest crimson to the purest white, and from the deepest purple to rose colour, and all these are of our own raising over the last five years from carefully selected seed. Originally I commenced with choice Irish seed, which was sown along the two sides of a beechwood fence running north and south, so that the seedlings were in shadow half the day. The small plants thus raised were pricked out in different situations, some in the open borders and others in shade, but I do not see that one place suits better than another. In two years they are fine plants, and they remain good for four years, after which I remove them to the wild garden. The flowers from old plants become smaller; and where so many are grown, it is too much trouble to divide them when they can be replaced so easily with seedlings which we expect to be of finer quality.

To maintain a progressive improvement in the strain I carefully weed out all inferior colours the moment they flower, and take great care of the best. I do not trouble to gather seed, but allow the plants to scatter their seeds around them, raking the ground and shaking out the seeds when ready. The seedlings are thus grouped around the parent plant, and as the good varieties are known the seedlings are safe. I believe we have thus obtained as good qualities in every colour as are to be found anywhere. In the early spring nothing can be more lovely than thousands of Primroses of every shade of colour. All our beds are edged with them, and they are also pricked out on the rockeries and on the permanent borders. They do not do well for massing, so we

have discarded them from the more formal spring bedding.—W. BROCKBANK, *Brockhurst, Didsbury*.

HAWKHURST HORTICULTURAL SOCIETY.

THE tenth annual Exhibition of the above Society was held under very favourable circumstances. As a consequence of the district comprising a very extensive and much-favoured part of Kent, the competition was and invariably is very keen throughout the Show. There is now no occasion for any open classes for plants to "make a show," the local plant-growers being quite equal to the emergency. There is yet, however, still room for improvement in the fruit and vegetable classes. Collections of vegetables were staged in numbers in two classes, but many were much too coarse, especially the roots. Liberal prizes were offered to cottagers, and a very creditable display of fruit and vegetables sufficient to fill a large tent was produced.

The premier six stove and greenhouse flowering plants were staged by J. C. Fisher, Esq. (gardener, Mr. C. Nicholls). Some of the best of these were the well-flowered examples of *Bougainvillea glabra*, *Erica Thomsonii*, and *Statice imbricata*. The best four exhibited by W. J. Neve, Esq., Cranbrook (Mr. F. Dean), included good plants of *Clerodendron Balfourianum* and *Allamanda Schottii*. Fine-foliaged plants were well shown by Mr. Nicholls; the Right Hon. G. J. Goschen, Hawkhurst (Mr. Gilmour); Mr. F. Dean; Captain Oakes, Sandhurst (Mr. Hodgkins); Sir E. T. Hardinge (Mr. Rummery), Hawkhurst, and others. The specimen of *Acalypha musaica* shown by Mr. Gilmour was strikingly beautiful. This exhibitor was also awarded the first prize for six exotic Ferns and four *Caladiums*. Of the former the specimens of *Davallia Mooreana*, *Adiantum gracillimum*, and *Gymnogramma peruviana* were very praiseworthy. The premier prize group of Fuchsias staged by Mr. Nicholls included beautifully grown specimens of Lucy Mills and Wave of Life. Lady Herschell, Hawkhurst (Mr. L. Barnes), also staged good Fuchsias. Mr. Hodgkins secured the first prizes for Gloxinias and Zonal Pelargoniums. Dr. Newington, Ticehurst (Mr. W. Salcombe), was awarded the first prizes for both twelve and twenty-four cut Roses. The blooms were fairly good in both instances.

The best collection of ten varieties of fruit shown by Mr. Barnes included good examples of Buckland Sweetwater and Mrs. Pince Grapes. Two other collections were staged. Mr. Milham, Rolvenden, secured the first prize for eight dishes of fruit. The best two bunches of black Grapes were shown by Mr. B. Reckes, Wadhurst Castle Gardens, the variety being Black Hamburgh. Mr. Barnes was a close second with Mrs. Pince, and in a corresponding class for white Grapes was placed first with well-coloured clusters of Buckland Sweetwater. The Melons shown as a rule were very poor, the notable exceptions being the premier prize fruit of Turner's Scarlet Gem and Earl of Beaconsfield, green flesh, shown by Mr. Gilmour and Mr. Hodgkins respectively. Cucumbers also were second-rate.

Mr. Barnes had the best collection of vegetables, but was very closely pressed by Mr. Gilmour. The latter put up a very fine dish of Stamfordian Tomatoes. Other successful exhibitors of fruit and vegetables were Mr. Milham; Canon Jeffreys, Hawkhurst; Mr. Iggulden, Mr. Willards, and others. Mr. W. Apps, Clive Vale, Hastings, exhibited, not for competition, some very fine Early Red Tomatoes, Tender and True and Earl of Beaconsfield Cucumbers, and some very close heads of Dean's Snowball Cauliflower.

Mr. Potten, Sissinghurst Nurseries, brought a good collection of plants, which added much to the variety of the Show. Among these we noticed the double-flowering tuberous-rooted *Begonias* Comtesse Horace de Choiseul, Phosphorescent, and Emilie Lemoine; and good single-flowering varieties were W. E. Gumbleton, Zambezi, and Potten's Exquisite. The most striking tricolor Pelargoniums were Masterpiece, Prince of Wales, E. R. Benyon, Empress of India, and Proteus. Good Zonal varieties were Gathorne Hardy, Dr. Denny, New Life, and General Grant; and of doubles Madame Thibaut, Nymph, Madame Thiers, and Lucie Lemoine. Mr. W. Knight, nurseryman, Battle, exhibited three boxes of cut Roses, many of which were very good, notably Marie Baumann, Dr. Andry, Camille Bernardin, Mdle. Marie Rady, Alfred Colomb, and Exposition de Brie. Messrs. G. Bunyard and Co., Maidstone, sent six boxes of very fine cut Roses, the colour of the majority being remarkably bright. Some of the best blooms were Capitaine Christy, Baron Haussman, Beauty of Waltham, La France, Etienne Levet, Madame Charles Wood, Elie Morel, Marie Baumann, Alfred Colomb, Duke of Edinburgh, and Magna Charta. An exhibition of arts and manufactures was held in connection with the Flower Show, and the grounds adjoining the residence of Sir E. T. Hardinge, Bart., were, with the park, open to the public.

POTATOES.

NEVER since I have been in the county of Wilts have I seen such an abundance of garden produce as there is in this neighbourhood at present. Cottage gardens especially are a pleasure to look at, and the contrast between this year and last is very remarkable. Potatoes, the poor man's vegetable, were last year quite a failure, while Groundsel and other quick-growing weeds seemed to have entirely taken possession. Hoeing was useless, and weeding seemed to be labour thrown away, for the weather, which proved so disastrous to the cultivated vegetables, was

exactly that which Groundsel, &c., delighted in. Now, although I must confess that Groundsel is not entirely absent, for there is such a crop from seed of last year as will take some time to get under, the Potatoes are a marvellous crop. I am digging Myatt's Prolific at the rate of 12 tons per acre, the quality of which, too, is excellent. It is not expected that any other patch will yield quite so well as this one, but everywhere the ground seems full of Potatoes, from two dozen to thirty large tubers turning up from a root; and even in some of the cottage gardens, where the seed which was planted was very inferior, the yield is extremely good.

That dread enemy the *Peronospora* is quite a month later in making its appearance, and I am in hopes that personally I shall not suffer much from its ravages; for although Potatoes were still growing fast when the first unwelcome blotches were seen in our neighbouring village, I decided that 8 to 12 tons an acre was worth being satisfied with, and had all the tops carefully pulled off the variety I have named, with the exception of a few for experiment, or rather for convincing unbelievers. I do not think it is of any use removing the tops after they become badly spotted, for the disease has then already circulated through the whole system. It requires, of course, a strong nerve and a hard heart to cart away the foliage while it is fresh and vigorous, but "half a loaf is better than none," and I shall be perfectly satisfied and extremely thankful if I can secure such a crop as we have at present. We have planted Borecole, Cauliflower, Broccoli, &c., between the rows of Potatoes where the tops have been removed, for the yield being so abundant the usual quantity of ground is not cleared, and some crops of Cabbages, Peas, &c., have had to be removed before they were half over to make room for the indispensable winter stuff.

Last year I was much afraid our good friend the old Ashleaf was going to leave us altogether, for more than half of it seemed to grow out of its true character, and it was very badly diseased. The truer the stock, the worse the disease and the less the crop seemed to be, but I am happy to say it seems now to have taken a new lease of life; and even those which were of doubtful character last year, and were on that account kept separate, have mostly returned to the normal habit. This is a great consolation, for none of the so-called improved Ashleaves are equal to this for earliness or shortness of haulm, both of which points are of interest to those who grow Potatoes in frames.

It is too early to say what late Potatoes will do. I am supposed to have only two varieties, Scotch Champion and Magnum Bonum. The Scotch Champion from seed saved here is growing moderately vigorous, and a great many small Potatoes are already at the roots. The purchased seed grows much stronger and flowers more profusely, but, from what I can see at present, is not making Potatoes so fast, yet I have no doubt about both stocks being true, as they are alike in all other respects. The Champion was last year of splendid quality, and although many were diseased and useless, there were more good tubers left than we had from any other sort. I cannot understand Champion being placed in the second class for quality. It was the only Potato I tasted last year which was equal to the imported German Reds, and good as they were when properly cooked, they were only half as good as Champion. Soils and seasons we know have a great deal to do with quality, and it may be that heavy soil and a wet season do not disagree with our Scotch friend. It is a pity it is not a more handsome tuber, but we have had many proofs that beauty and good quality do not always go together even in Potatoes.

Magnum Bonum was a fair crop with no diseased tubers, but that is all I can say for it at present, for although it was tried several times during the winter, spring, and even the summer, it was never fit to eat. It has been planted again in the hopes that a better season may make it palatable. There is one thing which ought to recommend it, at least to slovenly cultivators—there is not much chance for weeds to grow where it is planted. Its haulm is 5 feet high, even on poor ground, and its ample foliage is more than sufficient to smother the otherwise irrepressible Groundsel. When the disease has thinned its leaves and made room for the light to penetrate some Potatoes may be formed, but I have not much hopes before that time in this most luxuriant of seasons. Be it understood that I only speak of last year, and this in regard to Champion and Magnum Bonum, as I had no practical experience with them before.

Seed of the early kidney-shaped varieties cannot be looked after too soon now. I make a point of selecting them with great care, and place them up endways on boards in a cool shed at once, where they remain undisturbed till planting-out time. Last year I was amply paid for all this trouble, for although Potatoes all around were almost a complete failure, I had a very fair crop of Myatt's Prolific. Those who have to purchase early kidney varie-

ties for planting should always do so before winter; procuring them in spring is throwing money away.—WM. TAYLOR.

GLOXINIAS AND TUBEROUS-ROOTED BEGONIAS AT THE READING NURSERIES.

OF late years both Gloxinias and tuberous-rooted Begonias have, in common with many other choice flowering plants, been much improved by the efforts of hybridisers. The success attending these efforts is really remarkable; but what I am inclined to think also very important is, that their labours have probably been mainly instrumental in bringing into prominence the fact that both are easily propagated from seed. Not only can they be thus readily and cheaply increased, but what is very satisfactory, can, if the seed is saved from a good strain, be relied on for giving bloom equally as good as, if not superior in quality to, the originals. Seedlings, too, as with almost all kinds of plants, are very vigorous, being easily grown into good flowering plants the first season. By skilful treatment plants raised from cuttings (this applies more especially to the Begonias) are in one season grown into specimens, but in the majority of private growers' hands they are but puny objects as compared with the fine branching and floriferous seedlings.

Few growers have taken greater pains with the improvement of the strains of Begonias and Gloxinias than the Messrs. Sutton and Sons of Reading, and none probably have met with greater success. At the present time there are two houses filled with well-grown plants of grand varieties. The former from last year's sowing are now at their best, and for brilliancy and variety are fully equal to, if not superior to a house of Zonal Pelargoniums, as may sometimes be seen at Pearson's, Cannell's, and other nurseries. Names both with these and Gloxinias are entirely dispensed with, but every variety has its registered number. In addition to their own very superior seedlings all the best newest varieties advertised by English raisers and many continental novelties are regularly added. The strain has heretofore been rather weak in light varieties, but will be much benefited by the later additions of several raised on the continent. I also noticed several fine double-flowering varieties. The seedlings generally are exceptionally dwarf and branching in habit, bearing a profusion of large flowers of good form and substance. In other houses there are many thousands of healthy spring-sown seedlings, many of which will be grown-on to succeed those now in flower, the rest being grown to form bulbs for distribution.

The Gloxinias are grown in equally as large numbers and are also particularly good, either with regard to the blooms or the foliage, the latter being alone extremely ornamental, having a drooping or reflexed habit, so much so as to nearly conceal the pots in which they are grown. This excellent quality is noticeable in the innumerable spring-sown seedlings as well as in the large specimens 3 feet through. The former are flowered the first season in 4-inch pots, and several houses of them will shortly present a grand appearance, and to me are more attractive than larger plants, of which there are a great number now in full bloom. The value of the seed saved from these must be great, the strain being so excellent. Some of the flowers I had the curiosity to measure ranged from 4½ to 5 inches in diameter, the others being similarly large and of great substance and variety of colour. These measurements may appear exaggerated, but anyone can verify the truth of these and other statements by calling at the nurseries.

Dry bulbs and seed only are distributed by this firm, and probably their advice on the starting into growth of the former and the germinating of the latter may be of service to many of the readers of this Journal. To start the bulbs into growth it is advised that they be treated somewhat similarly to Dahlias, or in other words, that previous to being potted they be placed on a gentle and moist hotbed, potting them off when they have emitted roots. They are placed in small pots in the first instance, from which they receive a final shift into either 5 or 6-inch pots. The soil employed to consist of three parts turfy loam to one of leaf soil, with an addition of silver sand. For the seed pots or pans the quantities of soil are reversed—three parts well decomposed leaf soil to one of loam and some sand being recommended. Much importance is attached to the use of good leaf soil in preference to peat, especially in the early stages of growth. When sown, the seed is pressed into the surface of the soil, placed in a gentle heat—not necessarily bottom heat—covered with glass, and kept uniformly moist, and shaded. The seedlings are pricked off rather thickly in well-drained 4-inch or 5-inch pots, afterwards placed singly into small pots and gradually grown on.

The treatment of Gloxinias is substantially the same as that recommended for Begonias. In either case the whole of the packet of seed should not at once be sown, but the sowing ought to

extend from February to May; the latter month, and even June, being considered the most certain time of germinating the seed, which fact ought to be noted by inexperienced growers.—W. IGGULDEN.

[We have some Begonia flowers from Messrs. Sutton, which are very large and varied and brilliant in colour.—EDS.]

THE HOLLYHOCK DISEASE.

WE much regret having received during the week examples of this disease from Wiltshire, South Yorkshire, Essex, and Surrey,

which indicates that its outbreak is somewhat general. We can best reply to our correspondents by publishing the following admirable engravings and notes of the disease by Mr. W. G. Smith, which appeared in our columns six years ago.

"*Puccinia malvacearum* first appeared in Chili on a species of *Althæa*; it next appeared in Australia, where it proved extremely destructive to the Hollyhock (*Althæa rosea*, a native of China). Last June it was recorded from France, while at the beginning of July it had reached this country, where it immediately commenced its ravages on our Hollyhocks with great virulence, and completely killed to the ground all the plants it attacked both in

Fig. 19.—PUCCINIA MALVACEARUM, Mont.

A, Hollyhock leaf infected with the disease (natural size).

B, Pustules bursting through cuticle, with epidermal hairs, on which some of the spores are scattered. Enlarged forty diameters.

C, Section through pustule (or sorus), showing the clusters of uni-septate spores *in situ*. Enlarged forty diameters.

D, Group of uni-septate spores, seated on the distinct stems, or peduncles. Enlarged three hundred diameters.

E, Hairs from Hollyhock leaf, to show proportion between the hairs and the fungus. Enlarged three hundred diameters.

private gardens and in nurseries. From the south of England it rapidly spread to the north, and during the early spring of this year in certain districts near London nearly every leaf of *Malva sylvestris* was blackened by this new pest. It has also been recently common in France, attacking the indigenous *Malvaceæ*.

"The Hollyhock disease is remarkable for its extreme virulence, for on affected plants a black spot is not merely seen here and there, as in common with many species of *Puccinia*, but the

affected plants have every leaf blackened by these obnoxious pustules or sori, which are entirely composed of uni-septate spores seated on stems, as seen in section at C, magnified forty diameters. Every sorus contains more than ten thousand spores, and in the specimen sent for identification I counted more than a thousand sori on each leaf; therefore each individual leaf was capable of producing ten million perfect plants of the *Puccinia*. Figures altogether fail to give any idea of the enormous reproductive

powers of this mischievous fungus, and as for a cure none is known or likely to be known. The only method of stamping it out appears to rest in at once taking up and burning root and branch of every infected plant.

"The accompanying illustration with description, drawn from Nature with a camera lucida, will serve to give the readers of this Journal a good idea of the plant as seen under the microscope, and the smallness of the pest and its spores when compared with the hairs and breathing pores of the Hollyhock leaf itself."

Mr. Brotherton states on page 69 that he has prevented the spread of the disease by removing the affected leaves as they appear and burning them, and it will be instructive to know if the cuttings which he intends striking form plants free from the destructive malady. If any of our readers can state a remedy for this disease we will gladly publish it, as it is with regret that we have observed that the grand old plant the Hollyhock is seldom seen in gardens now.

GOOD NEW VEGETABLES.

I QUITE agree with your correspondent, Mr. Muir, on page 3 of the Journal, in relation to Carters' Defiance Cauliflower. Seed was sown in a cold frame on March 7th, the plants being grown in an exposed situation, and fine heads were ready for cutting about the 1st of this month. Veitch's Early Forcing Cauliflower was also sown at the same time, and grown exactly under the same conditions. I find it equally early; the heads are beautiful, white, and a little larger in size than Carters' Defiance. It is also a little larger in growth, but would have ample room to develop if planted 1 foot apart. Carters' Mont Blanc Cauliflower grows larger than the above two, and requires a little more space between the plants. Sown at the same time and grown by the side of the others it forms a good succession. It is just commencing to form heads. Ellam's Early Spring Cabbage is an excellent early variety; it hearts quickly, and is of moderate size and very hardy.—WM. BARDNEY.

NATIONAL CARNATION AND PICOTEE SOCIETY'S SOUTHERN SHOW.

JULY 28TH.

THE Show generally was fine, and some of the blooms will long be spoken of amongst those conversant with the qualities which constitute a good flower. Amongst those which were particularly fine were Admiral Curzon, s.b. exhibited by Mr. Dodwell in his stand of twelve which won first honours as the premier Carnation in the Show, and well it deserved to be placed in that position. It was particularly fine in colour, with beautiful bold markings, and such a flower is rarely seen of that fine old variety. The premier Picotee was won by Mr. Turner with a beautiful new flower named Baroness Burdett Coutts, a medium-edged purple, with a broad smooth petal and good in marking; it well deserved its position.

Amongst new Carnations Mr. Dodwell was awarded first-class certificate for Robert Lord, s.b. This variety I have previously said ought to have been premier last year. It was not so good as then, but still sufficiently fine as to strike the Judges as being worthy of the high honour conferred on it. In other scarlet bizzarres Mr. Dodwell also received first-class certificate for Arthur Medhurst, a fine flower with the markings of Admiral Curzon, but a fuller flower, with more petals than that fine variety—very promising and sure to please; also to a variety called Fred, which won second and third honours in its class, the flowers being only young but of fine quality. First-class certificates were also awarded to the following:—Crimson Banner, a c.b. (raiser, Mr. B. Simonite), grown and exhibited by Mr. James Douglas; very fine. Mr. Dodwell obtained a similar honour for the pink and purple bizzarres; one raised by himself and called Squire Llewelyn, a large full flower with splendid markings, not confused but nearly sure to be a telling variety. The other certificate was for a flower called Master Fred, raised by Mr. Hewitt of Chesterfield, a particularly fine flower with very bold markings, and when young high in colour, which tones down as the flower ages. First-class certificates were also awarded to Mr. C. Turner, Slough, for scarlet flake Figaro, raised by Dr. Abercrombie of Cheltenham, a fine flower with brilliant markings, and very pure in the white; a flower which will be indispensable in the future. Mr. Dodwell also obtained a similar award for John Bull, a scarlet flake of the largest size, with a broad and well-marked petal. Mr. Dodwell exhibited many other good seedlings in his stands, and to them may be attributed his being able to take first honours both in twelves and twenty-fours. Amongst the best were Thomas Moore, c.b., a flower of brilliant colour, and one

which is sure to tell. Mrs. James, r.f., a high-coloured flower, was particularly large and fine. Other good seedlings by the same grower were George Rudd, s.b., an improved True Briton, R. Holliday, c.b., and two sports in scarlet flakes from Admiral Curzon and Dreadnought respectively.

Picotees generally were well shown by Mr. C. Turner and Mr. Douglas; Mr. Turner being very fine with the following seedlings:—Baroness Burdett Coutts, winning premier as before stated; Mrs. A. Chancellor, h.p.p., a flower of the largest size with a fine heavy edge, no doubt the best flower in its class; Constance Heron, another fine flower with a heavy edge of brilliant scarlet; Lady Carington, a medium-edged rose of good properties.

The Society gave first and second prizes in each class for seedlings, for which there was a close competition; I, however, do not recommend this, as it is a great labour to select the best seedlings, and is sure always to retard the opening of an exhibition. A list of the awards and principal varieties is appended.—G. RUDD.

CARNATIONS.—In Class A, for twenty-four blooms, not less than twelve varieties, Mr. E. S. Dodwell, Larkhall Lane, Clapham, was awarded the first prize for a good collection, including the following varieties:—Ben Simonite, Rifleman, Admiral Curzon, J. D. Hextall, Thomas Moore, A. Medhurst, Squire Meynell, very fine; John Bull, William Monay, good form; R. Holliday, Robert Lord, a seedling, Dr. Masters, William Murray, John Keet, Florence Nightingale, G. Rudd, excellent; seedling s.f., and Unexpected. This collection was exceptionally fresh and bright, the blooms being of good form and the colours clear. F. Whitbourn, Esq., Loxford Hall, Ilford (gardener, Mr. Douglas), was second with a good collection, but some of the blooms were rather loose. The varieties were Falconbridge, Dreadnought, Sybil, Earl Stamford, Lord Lewisham, John Simonite, Clipper, Sarah Payne, Albion's Pride, Sportsman, and Juno. Mr. Charles Turner followed with Albert Chancellor, fine; Figaro, bright; Rifleman, and Diadem, among many other good blooms. Fourth, Mr. H. Hooper, Vine Nursery, Widcombe Hill, Bath. The above were the only exhibitors in the class.

In Class B, for twelve dissimilar blooms, the chief position was again obtained by Mr. E. S. Dodwell with neat blooms of the following varieties:—Master Ford, fine; Admiral Curzon, rich colour; Rifleman, large; Robert Lord, Sarah Payne, Thomas Moore, Squire Llewelyn, John Bull, Florence Nightingale, John Keet, and Mr. James, very fine. Mr. Douglas was second with a very even fresh collection; Mr. John Hines, Ipswich, third; Mr. Job Matthews, Wandsworth Road, S.W., fourth; Mr. John Buxton, Manor Street, Clapham, fifth; and Mr. H. Catley, Bath, sixth. There were six entries in that class.

In Class C, for six dissimilar blooms, Mr. Arthur Medhurst, Priory Road, was a good first with Admiral Curzon, Mr. James, Squire Meynell, Sarah Payne, Col. North, and John Bailey; Mr. H. Matthews, 439, Wandsworth Road, second; and J. Abercrombie, Esq., M.D., Cheltenham, third, these being the only exhibitors.

In Class D, for single specimens, there was good competition, over 150 blooms being staged. **Scarlet Bizzarres.**—Mr. Charles Turner was first with a fine example of Admiral Curzon; Mr. E. S. Dodwell being second, third, fourth, and fifth with Fred, Admiral Curzon, and Arthur. **Crimson Bizzarres.**—Mr. Douglas was first, second, and fourth with Rifleman, and fifth with Jenny Lind, Mr. Dodwell being third with a seedling. **Pink Bizzarres.**—Mr. Turner was first with Sarah Payne, second with the same variety, and fifth with James Taylor. Mr. J. Hines was second with Sarah Payne, and Mr. Douglas third with the same variety. **Purple Flakes.**—Mr. Douglas was first, second, and third with Earl Stamford, Mr. Turner fourth with Osmond, and Mr. Dodwell fifth with a seedling. **Scarlet Flakes.**—Mr. Turner was first with Jupiter; Mr. Douglas second, fourth, and fifth with John Bailey and Sportsman; Mr. Dodwell was third with a seedling. **Rose Flakes.**—Mr. Dodwell was first and fourth with seedlings, Mr. Henry Hooper second with Sybil, Mr. Douglas third and fifth with John Keet.

PICOTEES.—In Class E, for twenty-four blooms, not less than twelve varieties, Mr. Charles Turner was first with an excellent collection, in which were the following varieties:—Her Majesty, very fine; Baroness Burdett Coutts, Mrs. A. Chancellor, beautiful; Mr. Payne, Dr. Abercrombie, Luey (Addis), Constance Heron, J. B. Bryant, Lady Salisbury, Zerlina, Royal Visit, Brunette, good; Lady Boston, Rev. J. B. M. Camm, excellent; Lady Carington, Louisa, and Clara Penson. Mr. Douglas followed with good blooms of Princess of Wales, Royal Visit, Alliance, Brunette, and Mrs. Douglas. Mr. E. S. Dodwell was third; Mr. T. S. Ware, Hale Farm Nursery, Tottenham, fourth.

In Class F, for twelve dissimilar blooms, Mr. Douglas was first with a pretty collection including Brunette, very good; Mrs. Payne, Norfolk Beauty, Thomas Williams, Miss Williams, Nymph, Zerlina, Ethel, Mary, Rev. F. D. Horner, Edith Dombrain, and Morna. Mr. E. S. Dodwell was second with Minnie, Mrs. Matthews, Edith Dombrain, Mrs. Dodwell, Lady Louisa, Mrs. Payne, Novelty, Alliance, Ethel, Daisy, Lizzie Jones, and Tinnie. Mr. J. Matthews, Wandsworth Road, was third; Mr. John Hines, fourth; Mr. J. Buxton, fifth; and Mr. H. Catley, sixth.

In Class G, for six dissimilar blooms, Mr. Arthur Medhurst was first with Edith D'Ombrain, Mrs. Dodwell, Zerlina, Alliance, Thomas Williams, and Miss Lee; Master H. Matthews was second, and Dr. Abercrombie third.

In Class H, for single specimens, a large number of blooms were staged—viz., about 130. **Red Heavy-edged.**—Mr. Douglas was first,

second, third, and fourth with Brunette and J. B. Bryant, Mr. Turner being fifth with the latter variety. *Red Light-edged*.—Mr. Douglas was first, second, and third with Mrs. Williams; Mr. H. Hooper fourth with Grande Duchesse; and Mr. John Hines fifth with Clara. *Purple Heavy-edged*.—Mr. Douglas was first with Zerlina; Mr. Turner second, third, and fourth with Mrs. A. Chancellor; and Mr. E. S. Dodwell third with a seedling. *Purple Light-edged*.—Mr. Turner was first and second with Her Majesty, third with Clara Pension, fourth with Baroness Burdett Coutts; and Mr. Dodwell fifth with Ann Lord. *Rose Heavy-edged*.—Mr. Turner was first, third, and fifth with Mrs. Payne, second and fourth with Royal Visit and Fanny Helen. *Rose Light-edged*.—Mr. Turner was first with Mr. Allcroft and fourth with Lucy; Mr. J. Hines second with Mr. Allcroft; and Mr. H. Hooper third and fifth with Beauty of Bath. *Light-edged on Yellow Grounds*.—Mr. Turner was first with Miss Abercrombie, third with Lady Biddulph, fourth with Meteor, fifth with Lightning; Mr. Douglas second with Princess Beatrice.

In Class I, for twenty-four blooms not less than twelve varieties, of Sells, Fancies, or yellow grounds, Mr. C. Turner was first with Constance, Little Harry, Bertram, Mrs. Matthews, Gem, Duchess of Connaught, Zerlina, Field Marshal, Eurydice, fine; Lord Rosebery, Rosa Bonheur, Florence, Elysian Beauty, Martial, Captain Dalgety, Phœbus, Cupid, handsome; Elegant, Flirt, Ann May, Duke of Connaught, and Brighton Gem. Mr. Douglas was second, Mr. Hooper third, and Mr. T. S. Ware fourth.

In Class K, for twelve dissimilar blooms, the prizes were obtained by Mr. E. S. Dodwell, Mr. A. Medhurst, Mr. H. Catley, Bath; and Dr. Abercrombie, Cheltenham, in the order named.

In Class L, for twelve plants in pots, including Carnations and Picotees of distinct varieties in bloom, there were only two exhibitors, Mr. Charles Turner gaining the chief prize with healthy well-flowered plants of Queen of Summer, Mr. Payne, Louisa, Lord Chelmsford, Mr. Smart, Juliana, Lady Boston, Mr. A. Chancellor, Lothair, Her Majesty, and Rifleman. Mr. Douglas was an excellent second with Brunette, Prince of Orange, Fanny Helen, Her Majesty, Lothair, Mr. Rivers, J. B. Bryant, Lord Lewisham, Falconbridge, Clipper, Rifleman, and Cleopatra.

In the classes for seedlings Mr. Dodwell took four first and six second prizes. Mr. Douglas obtained one first and one second prize; and Mr. Turner was awarded five first and two second prizes.

At a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Col. R. Trevor Clarke in the chair, the following candidates were elected Fellows of the Society—viz., Sidney Reynett Brown, E. H. Cardwell, Henry Lee Corlett, George Deal, Miss Gowan, Captain Thomas Bridges Heathorn, Mrs. J. R. Hoare, Charles W. Pridham, and Ernest William Rogers.

— WRITING to us on GALVANISED WIRE, "W. A. B." has found a thick coating of paint prevent the leaves and growths of Vines being injured, but where the paint was thin the result was nearly as bad as with no paint at all. We shall shortly publish the results of some experiments with this and other wire that will not be devoid of interest to our readers.

— WE have received the schedules of the two following CHRYSANTHEMUM SOCIETIES—Kingston and Surbiton, which will hold its Exhibition on November 18th and 19th in the Drill Hall, Kingston, when in addition to liberal prizes in numerous classes, the twenty-five guinea challenge vase will be again offered. It will be remembered that this class is for forty-eight distinct Chrysanthemum blooms, to include twenty-four incurved and twenty-four Japanese varieties, and is open only to subscribers of one guinea. The Birmingham and Midland Counties Society will hold its Exhibition in the Town Hall, Birmingham, on November 24th and 25th, when numerous prizes will be offered for miscellaneous plants and fruit in addition to those for Chrysanthemums.

— SEVERAL of the new FRENCH DECORATIVE SHOW PELARGONIUMS are highly deserving of note. Mrs. Patton (Lemoine) is a fine light variety, with large excellently formed

flowers, pure white, with very dark blotches. It is of the type of the very useful Kingston Beauty, but far superior, and can hardly fail to become popular. Madame Thibaut, of the same raiser, is very distinct, the flowers being semi-double, almost circular, the centre white, the remaining portion warm rosy pink. Both these have been certificated. Two nearly pure white varieties, Madame Charles Koenig and Lucy Lemoine, will be useful for affording cut flowers, especially for bouquets.

— THE value and usefulness of VERBENAS IN POTS for decorative purposes could scarcely be better exemplified than is the case at Mr. H. Cannell's nursery, Swanley, Kent, where there is a house about 100 feet in length entirely devoted to these plants. An immense number of varieties are represented, the majority bearing fine compact trusses of symmetrical flowers that vary in colour through numerous shades of blue, purple, pink, crimson, and scarlet, some also being striped with two distinct shades of colour.

— A CORRESPONDENT submits the following as amongst the BEST DOUBLE PYRETHRUMS in cultivation:—Gloire d'Italie, crimson; Mdle. Menier, pink; Captain Boyton, scarlet, incurved, fine; Cleopatra, blush white; J. N. Twerdy, carmine, fine; Carneum plenum, pink; Lady Derby, crimson, extra; Mont Blanc, white; Niveum plenum, white; Marquis of Bute, bright crimson; Minerva, deep rose; Solfaterre, white, yellowish centre; Captain Nares, crimson, fine form; Rose Perfection, grand alike in colour and form; Kreimhilda, pink; Rembrandt, crimson, very fine; Omar Pacha, crimson; Emile Lemoine, carmine, tipped yellow; Gustave Nertz, pink; Princess de Metternich, white; and Rubens, deep rose.

— A CORRESPONDENT writes as follows on DIPLADENIA BOLIVIENSIS at Cannizaro House, Wimbledon:—"Eighteen months ago Mr. Jordan planted a newly-struck cutting in a bed of good soil in one of the stoves, allowing it to run up the rafters and along the side of the house. This plant is now producing hundreds of white flowers, which are most valuable when cut, and continue fresh for several days in vases. This is an excellent mode of growing this useful plant, and is worthy of notice."

— IN a recent part of Messrs. Cassell's "European Ferns" is the following passage in reference to FERNS THAT ARE EATEN:—"The young shoots of a handsome Tree Fern, *Angiopteris evecta*, are eaten in the Society Islands; the large rhizome is in great part composed of a mucilaginous matter, from which, when dried, a kind of flour is prepared. In the same islands the young fronds of *Helminthostachys zeylanica* are prepared and eaten in the same way as Asparagus. The young fronds of *Alsophila lunulata*, the 'Balabala' of the Fiji Islands, are eaten in times of scarcity; and the soft scales covering the stipes of the fronds are used by the white settlers for stuffing pillows and cushions in preference to feathers, because they do not become so heated, and are thus a real luxury in a sultry tropical night. In New South Wales the thick rhizome of *Blechnum cartilagineum* is much eaten by the natives. It is first roasted, and then beaten so as to break away the woody fibre. It is said to taste like a waxy Potato."

— AN experienced cultivator sends us the following note relative to the COLOURING OF GRAPES:—Grapes about colouring should have a thorough watering with liquid manure. A night temperature of 70° will be suitable with free ventilation whenever the weather permits. With a heavy crop more time for ripening will be required, and the night temperature in such case should be kept at 60° to 65°, allowing a free extension of the laterals, or the probability is the Grapes will shank. Muscats commencing ripening must have a minimum temperature of 70°, gradually rising to a maximum of 90° or 95° with abundance of air, which

is essential to the berries assuming their fine amber colour and acquiring their peculiarly rich vinous flavour. Mulching must be kept moist so as to keep the roots near the surface, which is essential to the well-being both of the fruiting and young Vines.

— THE usefulness and beauty of *CESTRUM AURANTIACUM* for covering pillars in conservatories or similar cool houses is well indicated by the handsome specimen now flowering in the greenhouse at Kew. This plant is bearing its dense trusses of orange or yellow-coloured tubular blooms in great profusion, and as it is similar in habit to the well-known *Habrothamnus fascicularis* the effect produced by such a display of brightly coloured blooms is most agreeable. For the latter plant it would form an admirable companion.

— WE have received two volumes of Weale's Rudimentary Series, published by Messrs. Crosby Lockwood & Co., London, entitled respectively the *TREE PRUNER* and the *TREE PLANTER*. These books, though containing some good practical instruction, are remarkable for including under the above titles notes on "the Geranium," "Thyme," "Sage and Savory," "the Wallflower and Antirrhinum," "Thrift and London Pride," "Coleuses," "Cinerarias," and "Achimenes," among many other similar plants—a peculiar instance of "book making."

— WE have received parts 5 and 6 of MESSRS. LETTS & Co.'s *POPULAR ATLAS*, which contains six carefully executed maps of Switzerland, Russia, Australia, New Zealand, and the Western Hemisphere. The chief physical features of the countries are indicated, and the populations of the most important towns.

— A CORRESPONDENT informs us that he recently saw at South Pierremont, Darlington, a fruit of the Duke of Edinburgh Melon of the extraordinary weight of 16 lbs. 11 ozs. The plant that produced it was placed in the bed on the 25th of April last.

— IN September, 1881, THE MANCHESTER ROYAL BOTANICAL AND HORTICULTURAL SOCIETY propose holding an unusually large exhibition of fruits, plants, and vegetables, to celebrate the fiftieth anniversary of the Society. We understand that every care will be taken [to render the Exhibition as complete and extensive as possible, and that fuller particulars of the prospective arrangements will shortly be announced.

— AT the Alexandra Palace on Friday and Saturday last Messrs. Cranston & Co., Hereford, had an EXHIBITION OF CUT ROSES, comprising in the two days nearly twelve thousand blooms, representing more than 160 varieties. The blooms were fresh and bright, and tastefully arranged in the central hall on a bank of moss, small Palms and similar plants being placed amongst them.

— A CORRESPONDENT, alluding to the accidental omission of the name of Mr. Scott from the names of the winners in ROSE CLASSES AT THE WIMBLEDON SHOW, states that this gentleman was awarded two first prizes, and his Roses excited the admiration of all visitors, possessing good substance, brilliancy of colour, and symmetry. He had a magnificent stand of Roses not for competition, the competitors in the cup class being limited to growers of not more than five hundred plants, while Mr. Scott has about a thousand. But this painstaking amateur Rose-grower, who is also Hon. Treasurer of the National Rose Society, cut all the blooms he could, and contributed greatly to the success of the Show.

— A CORRESPONDENT, "G. W.," wishes MUSHROOMS to grow in his meadows, and asks what process he is to pursue to attain the object desired. We shall be glad if those who have successfully established Mushrooms in meadows will communicate their experience on the subject.

— A CORRESPONDENT writes—"The Swedes appear to have found a new and effective way of making the COLORADO BEETLE known to all." He enclosed a portion of a match box of Swedish manufacture, upon which is delineated the above-named "beetle" busily engaged in destroying a leaf. The figure is fairly correct in colour and markings.

— AFTER a term of labour extending over thirty-three years MR. PETER GRIEVE, the accomplished gardener at Culford Hall, Bury St. Edmunds, has retired from his charge, and seeks the repose he so well merits. By his skill and devotion to his duties and his affable and genial deportment he enjoyed in a remarkable manner the confidence and esteem of his employer, the Rev. E. R. Benyon, whose service he only relinquishes in consequence of failing health. Mr. Grieve has done excellent work in the cause of horticulture. As a cultivator he occupied a high position, and he was the originator of the tricolor section of Zonal Pelargoniums of the Mrs. Pollock type, and was the writer of a prize essay on these plants that was widely distributed. But that Mr. Grieve did not by any means exclusively devote his attention to Pelargonium raising may be seen by a descriptive article on Culford Gardens in our issue of February 25th, 1875, wherein an excellent judge and cultivator, Mr. Douglas, speaks highly of the work in every department. We trust that Mr. Grieve's health will be speedily restored, and that he will long enjoy the esteem of his many friends. He will be succeeded in his charge by Mr. John Smith of Gunthorpe Hall, East Dereham, Norfolk, who enters on his duties about the middle of August.

— REFERRING to the CROPS NEAR CHIPPENHAM, "WILTSHIRE RECTOR" writes:—"Fruit, save bush fruit, is very poor in crop. As yet Potatoes are splendid, but I greatly fear that yesterday's (July 22nd) heavy storm and to-day's sultriness will bring on the disease."

— WE have received the PROCEEDINGS OF THE LIVERPOOL NATURALISTS' FIELD CLUB for the year 1879-80, which, in addition to particulars of the numerous excursions made by the Club, gives a most interesting lecture on "Floral Defences," by the President, the Rev. Henry H. Higgins, M.A., and an address by the same gentleman entitled "Biographical Sketches in Zoology from its Origin to its Union with Botany in the Science of Biology."

— IN celebration of the fiftieth anniversary of BELGIAN INDEPENDENCE a large HORTICULTURAL EXHIBITION was appropriately included in the great *fête* at Brussels. The Show was very fittingly solely national, not international, in its scope, and in consequence a detailed report of it would not possess special interest for our readers. That it was a great and a good Show none can doubt when such world-famed horticulturists as M. M. Van Houtte, Linden, Van Geert, Dallièrre, Jacob-Makoy, De Smet, Massange, Ghellinck de Walle, Vander Wouwer, and other celebrities put forth their strength; and that English visitors who attended the Exhibition and Congress were most hospitably received is what our frank and generous Belgian friends had by many previous instances of hearty welcome extended led them to expect. The time of year is not opportune for such exhibitors as those named to make a brilliant display, and Palms and fine-foliaged plants predominated at the Exhibition, which was opened by the King on the 21st inst.

— MESSRS. JAMES CARTER & Co. have sent us pods of TELEPHONE PEA. They are extremely large and fine, and similar to many we have seen in first-prize collections at various exhibitions this year. Experience has proved that this distinct Pea is one of the finest in cultivation, and is very valuable as a second early variety.

— IN reference to the class for SUBURBAN ROSES at the National Show, we have received letters complaining that a

prize was awarded in contravention of the schedule. We have referred one of the letters to one of the Honorary Secretaries of the National Rose Society, and are assured by him that the award in question has not escaped notice, and will be referred to the Committee at the next meeting. It was purely an oversight on the part of the Judges, who had overlooked the conditions when making their awards.

— THE EXHIBITION OF TABLE DECORATIONS at the Alexandra Palace is to be held on the 14th of August, and not the 7th, as announced last week, the entries closing on the latter date.

— IN a recent issue of *Nature* appear some interesting notes by Professor Baillon upon *PEPEROMIA ARIFOLIA*, an ornamental plant that is cultivated in the stoves of this country, the variety *argyreia* being an especial favourite. The leaves are peltate, and sometimes so much hollowed that they contain a quantity of water from sprinkling the plants or condensation. Small insects frequently fall into these little pools and are drowned. In referring to this Professor Baillon states that "Last year when the season was warm, and when the windows of the house were often open, the number of insects was very considerable, and these soaking in the water gradually decayed, and it was remarkable that during this there was not the least sign of any putrescent odour. Those who believe in the doctrine of insect-eating plants may perhaps in this be led to find an argument favourable to such a theory. They will add that the variety of colours so strikingly seen in these leaves constitutes the agent of attraction for the insects to come and be devoured."

ROYAL HORTICULTURAL SOCIETY.

JULY 27TH.

THE Society's meeting was on the occasion rendered doubly attractive and interesting by the exhibitions of Carnations and Picotees, and the British Bee-keepers' Association's Exhibition, which were held on the same day; but in addition to those attractions numerous plants and groups were submitted to the attention of the Committees. Not only was the Council-room occupied, but a large portion of the east quadrant was also filled with collections of plants notable either for their rarity, beauty, or fine healthy condition.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Mr. Gilbert of Burghley Gardens, Stamford, sent a dish of Peas called Reading Nonesuch, which was recommended to be sent to Chiswick for trial. Mr. G. Weedon of Ealing, sent some fruit of a Cucumber called Best of All, which has a strong resemblance to Tender and True. Mr. Sidney Ford, The Gardens, Leonardslee, Horsham, sent a Melon called Bellamore Hybrid, an oval green fruit, the flesh of which was tender and most delicious. It was awarded a first-class certificate. Mr. W. Kimpton, The Gardens, Smeeth Paddock, near Ashford, Kent, sent samples of a seedling Potato, which was recommended to be sent to Chiswick for trial. Messrs. James Carter & Co. sent fruit of their Cucumber Model, which is a useful variety, but was not considered superior to others in cultivation. Mr. John Maher, gardener to C. Allhausen, Esq., Stoke Court, Slough, sent a variety of Pea called The Queen, and a box of fine Violette Hâtive Peaches. To the latter a letter of thanks was awarded.

Mr. J. Wilson, Home Cottage, Enfield Highway, sent a seedling Currant raised from Raby Castle, to which it bears so close a resemblance that no difference could be distinguished between them. Mr. Pearson, Water Lane, Brixton, again exhibited his seedling Strawberry, but the flavour was so inferior that the Committee could not make any award to it. Messrs. Hooper & Co., Covent Garden, sent a Melon called Sirdar, which was not of sufficient merit.

Messrs. C. Lee & Son, Hammersmith, sent a basket of Henson's Seedling Gooseberry. This variety received a first-class certificate a few years ago, and still maintains the high opinion then formed of it. A letter of thanks was awarded. Mr. E. P. Dixon of Hull sent fruit of a new Raspberry derived from the Northumberland Fillbasket. It is a large handsome fruit, but not superior in flavour to other varieties in cultivation.

Messrs. Rivers & Son of Sawbridgeworth sent nine varieties of Cherries grown on pot trees in an orchard house; the finest of all was Early Rivers, a variety certificated by the Committee some years ago. Grosse Guigne Noire Luisante was also very fine. A letter of thanks was awarded for the collection. Messrs. Rivers also exhibited eighteen fruit trees in pots, which were so much admired for the excellence of their cultivation that a silver gilt Knightian medal was awarded. Mr. Stephen Castle, The Vineyard, King's Lynn, sent a collection of Tomatoes, to which a cultural commendation was awarded. Mr. Sidney Ford sent a collection of Potatoes consisting of forty-three varieties, to which a bronze medal was awarded.

FLORAL COMMITTEE.—Dr. Denny in the chair. The following were the most notable exhibits in the Council-room. Messrs. John Laing and Co., Forest Hill, sent a fine collection of Hollyhock blooms, including some remarkably handsome varieties; the blooms were of great size, full, and of good form. Mr. J. Chambers, Westlake Nursery, Isleworth, sent a collection of Lobelias and Ferns, young specimens of *Asplenium viviparum* being particularly attractive with their finely divided fronds bearing diminutive plants. Mr. G. Weedon, Ealing, staged a basket of a bedding Lobelia named Gem of the Season, dwarf and free, the colour of the flowers being a very bright blue. Mr. R. Dean, Ranelagh Road, Ealing, exhibited flowers of a double Stock named Mauve Beauty, very profusely flowered; also specimens of the double Mayweed, *Matricaria inodora* fl.-pl., and samples of two seedling Potatoes, The Alderman and Lord Mayor, both crosses obtained between Extra Early Vermont and Early Market. Messrs. Veitch, Chelsea, sent several new and beautiful plants, including a very attractive dwarf Tuberous Begonia with pendulous rich scarlet flowers; a white-flowered variety named Mrs. Sheppard, of considerable beauty; a variegated form of *Lilium longiflorum*; a plant each of *Oncidium dasyle*; and a variety named aureum with bright yellow labellums. Messrs. William Paul & Son, Waltham Cross, sent a box of seedling Roses. Messrs. J. Carter & Co., High Holborn, exhibited plants of *Tropæolum Chameleon*, a dwarf compact variety with neat flowers marked with crimson and yellow, and several good Balsams. Mr. J. Smith, Tollington Nursery, Hornsey Road, sent two *Fuchsias* named President and Magnum Bonum, both having large flowers with purple corollas and scarlet calyxes. Messrs. Standish & Co., Royal Nursery, Ascot, staged specimens of a Phlox named Standish's Perfection, a fine variety with large white flowers in compact trusses. Mr. B. S. Williams sent several new plants, *Cattleya Eldorado virginialis* being particularly attractive. Mr. Stephen Brown, Weston-super-Mare, sent a collection of Coleuses; and cut flowers of Pentstemons were exhibited from the Society's garden at Chiswick. Messrs. T. Rivers & Son, Sawbridgeworth, sent about twenty fruit trees in pots, comprising Pears, Cherries, and Apples. One tree of Bigarreau Napoleon was remarkable for the fine crop it was bearing. A vote of thanks was accorded to W. A. Wallington, Esq., Trowbridge, for cut blooms of Carnations.

In the east quadrant, however, the principal collections of plants were staged, and by far the largest and most remarkable of all was that from Captain Patton of Abbey Road, which is referred to in another column under the report of the Royal Horticultural Society's Evening Fête. We were glad to notice that it had been partly re-arranged so as to avoid that crowded appearance which was noticeable previously. The plants composing the group having being noted in the report referred to, it is needless to repeat them here, but the merit of the collection was justly recognised by the award of a large gold medal. We understand that the group will remain on view until the Popular Show on August 2nd.

Messrs. James Carter & Co., High Holborn, exhibited a large collection of their Challenge Prize Balsams, which well indicated the excellence of the strain they possess. The majority of the plants were in 48-size pots, were a foot to 18 inches in height, and bearing a profusion of large blooms of good form and substance. The lilac, mauve, and purple shades were particularly well represented; white, flesh, pink, and scarlet were also remarkably fine. A silver Banksian medal was awarded. Messrs. Osborn & Son, Fulham, sent a neat collection of fine-foliaged plants in fresh healthy condition. The central plant was a vigorous specimen of *Acalypha musaica*, the foliage large and well coloured. In addition to such well-known elegant Palms as *Areca Baueri*, *Kentia australis*, *K. Wendlandia*, *K. Canterburyana*, and *Cocos Weddelliana*, small specimens of the dwarf and pretty *Pandanus ornatus*, *Aralia Veitchii*, and *A. filicifolia* were shown.

Messrs. Charles Lee & Son, Hammersmith, were awarded a silver Flora medal for a large and beautiful collection of ornamental shrubs and Conifers in pots. The specimens staged were mostly small, but well showed the distinctive habit and colouring of the different species and varieties. Some of the most noteworthy forms exhibited were the following:—*Platanus californica*, a very distinct species with enormous leaves more than a foot in diameter; *Populus canadensis aurea*, an elegant Poplar with neat golden-yellow leaves; *Ulmus campestris variegata*, a beautifully variegated Elm, the markings on the leaves somewhat resembling those in *Ficus Parcelli*; *Castanea vesca alba marginata*, an elegant variety of the English Chestnut with narrow leaves edged with an irregular band of white; *Sambucus racemosus*, remarkable for its large corymbs of small scarlet berries; *Quercus atro-purpurea*, a form with very dark purple flowers; *Quercus Cerris elegantissima*, a variety of the Turkey Oak with neatly variegated foliage; *Acer campestris variegata*, a charming little Maple with small leaves freckled with white; *Quercus filicifolia*, a peculiar form with deeply divided leaves, the segments being irregularly linear; *Æsculus laciniata* was also remarkable for the narrow dark green peculiarly cut segments of the leaves; *Quercus purpurascens* had rich purple foliage, and many other beautiful forms were represented.

Mr. H. Cannell, Swanley, Kent, exhibited a beautiful collection of single Petunias, fine in form, and particularly rich in colour. The blooms, as seen in contrast with a carpeting of Fern fronds, appeared remarkably well. The collection was flanked by four plants of *Achimenes longiflora major*, with uncommonly large flowers; also a collection of African Marigolds. This little group was generally

admired by the visitors. Mr. W. Rumsey, Waltham Cross, contributed seven boxes of neat and fresh-cut Roses, comprising a number of excellent varieties in very good condition. Some of the best were Leopold Premier (very neat and fresh), Madame Victor Verdier, John Stuart Mil' Dr. Andry, La Rosière, and an excellent dozen of Alfred Colomb—bright, of good form and substance. A bronze Banksian medal was awarded. Messrs. James Veitch & Sons, Chelsea, exhibited eighty blooms of border Carnations and Picotees grown at King's Road, Chelsea, comprising a large number of excellent varieties. Among the Carnations the most noticeable were Lord Chelmsford, R.F.; Sulphur King, yellow self; Crimson Pet, a rich crimson self; Purple Prince, fine purple self; and Mrs. Teigner, fine pink self. Of the Picotees Mrs. Rayner, rose, medium edge; and Lady Armstrong, a heavy red-edged variety with a yellow ground.

First-class certificates were awarded for the following plants:—

Lygodium palmatum (G. F. Wilson, Esq., F.R.S.).—A beautiful climbing Fern, which was stated to have been grown upon a rockery and unprotected for several winters. This is one of the most elegant and free-growing Lygodiums in cultivation, and proves of considerable value for training up pillars in greenhouses or conservatories.

Rose Duchess of Connaught (C. Noble, Bagshot).—A Hybrid Perpetual of rich crimson hue, neat form, and possessing a particularly powerful and agreeable fragrance.

Rose Mrs. Jowitt (Cranston & Co.).—A handsome Hybrid Perpetual, of symmetrical form, great substance, and a glowing rosy crimson colour. Very beautiful.

Macrostylis metallica (Veitch).—An attractive dwarf terrestrial Orchid, with neat foliage of a shining metallic deep brown colour, with a crenated margin. Very pretty for culture in pans on stages in stoves or Orchid houses.

Oleobachia palustris (Williams).—A graceful table plant with digitate leaves, the divisions being narrow and rich shining green in colour. The habit of the plant is compact and dwarf.

Iris Kœmpferi, vars. *Crimson King* and *Magnificence* (Veitch).—Both these varieties were of exceptional size and rich in colour, the former being particularly beautiful, the shade of crimson being intensely bright and clear.

SCIENTIFIC COMMITTEE.—Mr. W. G. Smith exhibited a specimen of *Pyrethrum* more or less fasciated and bearing a proliferous head—the so-called “hen and chickens,” not uncommon in the Daisy. Mr. Roberts, Penzance, forwarded specimens of the following rare British plants:—*Chara fragifera* (living), *Allium Schönoprasum* var. *sibiricum*, *Orobancha rubra*, and *Erica vagans* (dried) from the Lizard, Cornwall. The Rev. G. Henslow exhibited a foliaceous and proliferous *Trifolium repens*, and called attention to the fact that while the sepal-teeth grow out into petiolate leaves, stipule-like processes appeared at the top of the calyx-tube between the petioles, seemingly proving that the tube is really receptacular and not of calycine origin. Mr. Fletcher of Ottershaw forwarded male cones of *Araucaria imbricata*.

Mr. Cheshire being subsequently about to lecture on bees, the Rev. G. Henslow took the opportunity to speak principally on the fertilisation of flowers by them and other insects.

A basket of *Tropæolums* furnished illustration of strong “proterandry”—i.e., the stamens, maturing first, rise up in front of the orifice to the spur and then retire on shedding the pollen. Subsequently the stigma matures and takes up the same position; hence such a flower is fertilised by pollen brought from a younger one. Fuchsias illustrated the false generalisation that, whether a flower be pendulous or erect, the stigma will be below the anthers, so that the pollen may fall upon it. Though such an arrangement is in the *Fuchsia* the flower is proterandrous, and therefore is not adapted to self-fertilisation. Moreover, when flowers are habitually self-fertilised the anthers are placed in close contact with the stigmas, as is the case with the “cleistogamous” buds of Violets. A group of *Pentstemons* furnished the case of a flower fertilised by bees, but which by means of the fifth (abortive) stamen standing over the nectary, afforded an obstruction to all insects whose proboscis could not reach to the bottom of the tube, and so would not be of any assistance in pollinating the flower. The structure of *Abutilon*, *Malva sylvestris*, and *Salvia* was described as being especially adapted to insects in securing cross-fertilisation, while cleistogamous Violets and *Malva rotundifolia*, &c., were self-fertilising.

The lecturer observed that all the varied beauty of flowers in nature was solely due to their being adapted to insects, whilst self-fertilising flowers were inconspicuous and unattractive. A plant of *Lygodium palmatum*, exhibited by Mr. Wilson, illustrated the peculiarities of climbing stems or “twiners,” and the lecturer suggested that as the property of bowing in a circular manner was not confined to climbers, for the apex of a Pine does the same, that it is probably a general phenomenon of plant growth, but specially utilised by plants with weak stems as a means of support.

THE following plants were certificated at Chiswick on July 20th.

BEGONIAS.

Dr. Denny.—Strong vigorous habit, very free-flowering. Flowers of medium size, well thrown above the foliage, very pale scarlet, approaching almost to a salmon.

Dr. Hogg.—Very strong growth. Stems pale green. Flowers well displayed, of a very bright scarlet, shaded towards centre with a pale hue. Very free-flowering and good.

Lucy Violet.—Vigorous habit, very free-flowering. Flowers of medium size, clear rosy pink, shaded towards the centre of the flower.

Anna Ria.—Strong vigorous growth, very free-flowering. Flowers of medium size, pale scarlet. Good.

Lizzie Smith.—Free vigorous growth. Flowers dark scarlet, with distinct magenta shade; round, medium size.

Henry Webb.—Strong vigorous habit, free-flowering. Flowers large, of good form, clear scarlet. Very good.

Annie Wilkie.—Strong habit. Stems pale green. Flowers large, pale scarlet, well thrown up. Very good.

Nellie Barron.—Very close compact habit, very free-flowering. Flowers erect, of a beautiful dark scarlet. Very fine.

Rosea Grandiflora.—Tall erect habit. Flowers very large, of good substance, beautiful rosy pink.

The certificates which had been previously awarded to the varieties Nellie May and A. Hemsley were on this occasion confirmed.

All the above varieties were raised in the Royal Horticultural Society's Gardens.

PELARGONIUMS.

Gloire d'Orleans (Lemoine).—Of dwarf close habit, very free-flowering, medium, erect-growing truss, beautiful magenta scarlet. The brightest coloured in the Ivy-leaved section.

Lucie Lemoine (Lemoine).—Show-Decorative. Very dwarf close growth, very free-flowering. Flowers pure white, slightly pencilled at bottom of petals. The best white.

Mrs. Potten (Lemoine).—Show-Decorative. Free habit, free-flowering, white, slightly shaded; distinct purple blotch on upper petal. Very distinct and showy.

Madame Thibaut (Lemoine).—Show-Decorative. Free vigorous growth, very free-flowering. Large compact truss, white suffused with magenta; distinct, broad, and irregular rosy margin round petals. Very fine and showy.

Mont Blanc (Lemoine).—Ivy-leaved, white shaded pink, very free-flowering, large truss. Very fine.

Similar awards were also made to the two following plants on the same occasion:—

Gomphrena globosa nana compacta (Benary).—A very fine dwarf free-flowering form of the Globe Amaranth, from 9 to 12 inches high.

Oleander Professeur Duchatre (Huber).—Flowers purplish wine colour, beautiful shade, free-flowering and very showy. The darkest-coloured of any.

STRAWBERRY PAULINE.

THE enclosed letter from Mr. Ruffett of Panshanger, a fruit grower and exhibitor well known to your readers as no mean authority, confirms your observations and our experience as to the value of this now well tested Strawberry. Mr. Turner's remarks on page 66 savour too much of *cathedrâ* utterances—that, because not good at or coming from Slough, a Strawberry must necessarily be worthless. We remember showing Pauline in 1877 at the Crystal Palace Rose Show, and Mr. Turner admiring it; and we sent him plants in August, 1877, for trial. His experience consequently, is not so long as ours.—PAUL & SON, Cheshunt.

“Pauline Strawberry is by far the most useful early Strawberry I have ever grown, quite ten days earlier than Keens' Seedling with exactly the same treatment. The plant is of good constitution and a great cropper, only second-rate in quality, but its extreme earliness makes it invaluable.—W. RUFFETT.”

DRAINAGE OF LAND.

THE wet and sunless summer and autumn of last year will have shown those having ill-drained gardens how important it is to have the means of carrying off superfluous water. Whether it is for vegetables, trees on walls, plants under glass or cultivated in pots, a thorough drainage is the first thing to be secured, and of the greatest importance. One might prepare a most suitable soil for a plant in a pot, but if the drainage is carelessly placed in, and the soil is soon washed into it, the plant will quickly become unhealthy. If it be so in the case of plants in pots, why should it not be likewise applicable in the open ground? In proof of the above remark, I may mention having read of the general failure of Peaches outside this year; but in some cases it was remarked one cultivator had a moderate crop of fruit, while his neighbour had not one. How is this? I fancy someone saying, “One was well sheltered and the other very much exposed.” This would be a reasonable reply; but the answer I would give to such a question would be, “One border was well drained and the other was not.” I remember reading some time ago a paper written by one of our leading agriculturists, and in it he said he did not consider drainage necessary providing the land was deeply cultivated, but I would advise good drainage and deep cultivation combined. This, with proper after treatment, will be the means of making an unsatisfactory garden productive, and one that is late comparatively early. Bringing forward this subject early in the season will enable those—seeing the great importance of good drainage to their soil—to lay down their plan to be carried

out next winter. I will consider the subject in a future issue.—
ROBERT D. LONG.

GERANIUM PRATENSE FLORE-PLENO.

THE ordinary double variety of this old British species is well known and is attractive as a border plant, but the continental form

represented in fig. 20 far surpasses it, and is unquestionably one of the most effective border plants in cultivation. The flowers are perfectly double, large, and well formed, and are borne in great profusion. The plant is more dwarf than the ordinary double variety, growing from 18 inches to 2 feet high according to the nature of the soil, and forming a compact bush covered with hundreds of bluish-purple flowers. The spray figured was gathered

Fig. 20.—GERANIUM PRATENSE FLORE-PLENO.

from a plant in Mr. Laxton's Experimental Garden, where its superiority over the familiar type was very apparent, for both were growing together. This is a border plant of the first order of merit, and no one seeing a well-grown specimen can fail to admire it, and there are few growers of hardy flowers who would not desire to possess it. The lower leaves are much larger than those produced on the stems, and one of them is shown in outline behind the spray. The plant continues expanding its flowers

over a considerable period, and thus remains a long time in beauty.

THE WEATHER AND THE POTATO CROP IN IRELAND.—I see on page 70 of the Journal that the Potato disease has appeared in several parts of England. I have much pleasure in stating that with us, or in this locality generally, so far there has not been a trace of it. I have recently been through much of Munster,

and that district is also exempt. Correspondents from other parts of Ireland, except in one or two isolated localities, confirm these facts. This means millions—much more than the most beneficial legislation—to the humbler classes in Ireland. We grow Ashleaf Kidney, Early Rose, Flourball, and Flounders for early crop; for late—Champions, Scotch Downs, &c. All are in admirable condition, especially Champions, 4 feet high with fine upright haulm. The weather is favourable.—W. J. M., *Clonmel*.

A DAY IN BEDFORDSHIRE.—No. 1.

JUST before the occurrence of the heavy storms that were so general about the middle of the present month I found myself journeying from London to Southill station *via* Hitchin, my destination being Old Warden, a picturesque village four miles from Biggleswade. The bulk of the hay crops between London and Hitchin were fortunately secured, but those in the valley of the Ouse were only just cut, and many tons of the produce have been unhappily washed away. The grain crops of the district traversed between Hitchin and Bedford were full, bold, and upstanding—a bountiful prospect then, but now the crops are flattened to the earth. Strawberries in the gardens were most abundant, and much fruit was gathered before the storms occurred, but a vast quantity was destroyed by the heavy and continued downpour and rotted on the ground. Roses and flowers, generally so fresh and bright on the 10th inst., were a week afterwards dashed in pieces, and a flourishing district was despoiled of its beauty, causing disappointment and loss to gardeners and farmers. This, it is feared, is but an example of the effects of the storm that was almost general, and which will be seriously felt for a long time by those engaged in the cultivation of the soil; but I must refer to

OLD WARDEN.

This, the ancestral seat of the late Lord Ongley, passed by purchase during the lifetime of the last lord of that title into the possession of Joseph Shuttleworth, Esq., whose Lincolnshire mansion—Hartsholme Hall—was illustrated and the gardens described in the *Journal* of March 9th, 1876.

The time is not opportune for telling the story of the life of the squire of Old Warden, but whenever it is written it will be one of the many instances that could be cited, that a life of well-applied labour founded on sound judgment brings a reward to those who see in advance a coming want and promptly determine and unceasingly labour to meet it. This is what Mr. Shuttleworth and his colleague Mr. Clayton have done. These once manual workers, seeing further than their fellow men, were the pioneers of the steam machinery revolution as applied to agriculture, and they now admittedly stand at the head of that industry, which has proved of incalculable benefit to the whole civilised world. Those who have achieved results so great deserve a fitting reward, and Mr. Shuttleworth merits, amongst other marks of distinction, the position he adorns as a magistrate of two counties, a director of the Great Northern railway, and a member of the Council of the Royal Agricultural Society of England, besides being High Sheriff elect of the county of Bedford.

So much in brief relative to the owner of Old Warden, and now let us glance at the estate. It consists of about three thousand acres of excellent land, principally arable, meadow, and market gardens, with a moderate extent of woods, a richly timbered and beautifully undulated park, a noble mansion, fine pleasure grounds, a small garden, and model village. The garden will probably be larger some day, a commencement having been made by the erection of an admirable range of glass by Messrs. Foster and Pearson. The alterations and improvements that have been in progress during the past four or five years have been most extensive and costly, and instead of being surprised that a garden commensurate in size with the mansion and estate has not yet been made, the real wonder is that so much has been effected. The old mansion was taken down, and a fine structure in the Tudor style has been erected on the site, everything having been done that skill could accomplish and science suggest to render it complete. The striking feature of the building is the castellated clock tower, the clock being a reduced counterpart of that in the tower of the Houses of Parliament at Westminster, the chimes of both being identical. This massive building in Bath stone has a fine effect as viewed amongst and rising above the grand old Elms, Oaks, Limes, and Beeches in the park. The stables adjacent are appropriately massive and ornamental. This is not the place to describe them, but it may be said that they are not surpassed if equalled in the Queen's dominions. All the farmsteads on the estate have been rebuilt in the most approved manner. Cottages in the village have been renovated or rebuilt, and furnished with all necessary appliances for making them healthy and comfortable homes. The once

rough rising banks from the road to the cottage gardens have been turfed, two rows of bricks on edge forming the base above the road level. Evergreen and flowering shrubs have been planted in prominent positions with Ivy and creepers for the dwellings; the whole being kept in order, the Ivy cut once a year, the green Holly hedges with fine standards of the Golden Queen at intervals trimmed at the proper season, and the turf banks kept like a lawn by Mr. Allis, the gardener; indeed the village appears like a portion of the pleasure grounds. The great amount of labour necessitated on the estate has been of great advantage to the village and district, especially during the last two severe winters, when work was always found for willing workers.

We pass to the pleasure grounds. These are wholly on one side of the house, extending in a north-easterly direction to what is the great feature of the grounds—the Swiss garden. Some grand old Junipers and Cypresses tower aloft from the lawns, and the walks pass under a thick canopy of foliage of the closely planted deciduous trees, which have an undergrowth of Laurels. There are avenues of Yews and Spruce with cool grassy glades, and here and there specimen trees and Conifers in commanding positions. Only one of these need be noticed, and that only about 9 feet high, but it is *Abies pygmaea*; and a specimen of that diminutive Spruce, a dense cone of the height named, with a base 8 feet in diameter, is not often seen. During several years of absence of Lord Ongley the grounds were neglected, and much labour will be required to put all the trees, shrubs, &c., in order; but a commencement has been made, and all will be accomplished in due time.

The Swiss garden has been “brought round,” and a more picturesque and thoroughly enjoyable enclosure than this is scarcely to be imagined. It may be described as the life work of Lord Ongley—the “old Lord” as he is termed, and unquestionably a vast amount of labour and great taste have been employed in its formation. It is an enclosure of eight acres, but so planted and arranged as to appear considerably larger. It has been thoroughly renovated and improved, Mr. Allis having in this work had the valuable guidance of Mr. Milner, the well-known landscape gardener. The enclosure is sheltered by trees on three sides, being partly open to the south, and is surrounded by a gravel walk, from which most picturesque views are had of the ground below; for the enclosure may be generally described as a hollow, but broken by bold mounds and groups of trees on raised stations—indeed it is a series of deep grassy dells, and elevations more or less abrupt. Here and there are fine specimen trees—Cedars of Lebanon, lofty Junipers, luxuriant and graceful Hemlock Spruces, and fine examples of *Araucarias*, two of which, the male and female forms, have produced many cones. There is a miniature grove and Spruce avenue, with a narrow tortuous stream enclosing small islands and forming little cascades; ornamental bridges cross the stream, and large wired arches are thrown across the glades for Vines and Roses, &c. There are Rose trees—real trees—by the sides of the walks laden with a wealth of bloom, old varieties whose names are forgotten, but most beautiful and sweet. In a prominent position is a Swiss cottage—not a mere apology for a structure of this name, but a beautifully finished edifice that was once the home of the keeper of the garden, but not now permanently occupied. This quaintly attractive cottage and its well-planned site is exceedingly ornamental. Almost in the centre of the grounds, and hidden from view but for the glimpse of a dome of glass which appears as if growing out of the ground and protruding through a mass of vegetation, is a glass structure with a semicircular roof. It appears to have been formed to shelter the old *Wistarias* that cover the roof. This almost buried structure is entered by long passages, into which light is admitted here and there through stained glass windows. These arched corridors were originally of plain brickwork, but they have been transformed into stalactite caverns by Mr. Pulham of Broxbourne, who with great skill has imparted to the interior a singularly romantic appearance. In the walls pockets have been formed for Ferns and other suitable plants, which Mr. Allis is establishing as rapidly as possible. This rugged, grotesque, and almost subterranean fernery comes as a surprise from the great expanse of smooth and admirably kept lawn of the garden, and once fairly out of the passage the stranger would be a little puzzled to find the entrance through the skilfully planted shrubs. The prevailing greenery of the garden with its Ivy-clad banks has been relieved and the effect brightened by Golden Yews, Golden *Acacias*, variegated Hollies, and other choice flowering and deciduous shrubs which have been freely yet tastefully planted by the present owner. Statuary, appropriately ancient, is also placed in different parts of the grounds. It is a beautiful and extremely diversified garden, and is worthily cherished both by its owner and gardener. It contains, however, few flowers, Mr. Allis with good taste almost limiting

these to Foxgloves and other hardy flowers that are allowed to establish themselves among the shrubs in pleasing informality.

Only brief reference can be made to the kitchen garden, in which a choice selection of fruit trees has been planted, and the range of glass above referred to erected. The Vines are very strong, short-jointed, and full of promise. Laterals are allowed to grow down to the ground, and consequently the rods have swelled freely to the base. The few bunches which have been safely permitted are very fine. Foster's Seedling and Buckland Sweetwater have exceptionally large berries; bunches of Gros Guillaume will exceed 6 lbs. in weight, and Black Hamburgs and Muscats are also excellent. A well-drained border with plenty of water and mulchings of rich manure to the roots, and laterals thinly trained 18 inches from the glass, are what Mr. Allis rightly considers cardinal points in Grape culture. The Peach houses contain healthy trees of the best varieties, some—including Plums, Pears, and Cherries—being in pots for present bearing. Figs are planted for covering the back walls of the Peach houses, those of the vineries being covered with Tomatoes, which are very strong, and producing fine fruit of Carters' Green Gage, the favourite variety at Old Warden.

Outside were full crops of vegetables. Strawberries were abundant. For size with high quality Dr. Hogg bears the palm; Sir Joseph Paxton and Omar Pacha were producing an abundance of very large fruit; fine also was Bradley's Amateur, which by its firmness is an excellent traveller. As Onion-sowing time is approaching, it may be useful to mention that the best in the beds sown last August was the old silver-skinned variety, that is usually sown in the spring for pickling purposes. The bulbs far excelled those of Silver Queen, and indeed all other varieties. When sowing winter Onions other cultivators may well try a few rows of the variety referred to. Another simple matter may be mentioned, as simplicities are sometimes overlooked by writers on gardening. A scarce article at Old Warden was Mint, and, curiously, when it was wanted Mr. Allis could not find a vendor. He found, however, a few sprays, inserted them like Verbena cuttings in pots of sandy soil in heat; in a few days they rooted, were topped, and inserted again, until he soon had large flat pans full—Mint in abundance, and to spare. Those who have large supplies of forced Mint to provide in winter and spring should try this plan of providing it; it is possible it will surpass all others. Insert the cuttings an inch apart in spring, when rooted plunge the pans in a convenient position in the garden, and a fine vigorous Mint store is provided ready to hand for placing in heat as required.

Just a word on the gardener's garden, because it contains remarkable bushes of the distinct and beautifully striped old Rose Rosa Mundi, which is rarely seen now in such numbers and condition, there being hundreds of fine flowers in colours resembling clear rose flake Carnation. Behind this pretty cottage is what is termed the Warren, some acres of remarkably straight and tall Scotch Firs and Larches, with long avenues of Spruce, and an undergrowth of Ferns—a cool and delightful retreat.

I had almost omitted to note that the Warden Pear is reputed to have been raised by the Monks of Warden Abbey, a few relics of which exist; it is a baking Pear, and supplied the contents of the celebrated Warden pies. Under this name baked Pears from Warden were hawked in Bedford not many years ago under the name of "Wardens all hot." It may be noted, too, that this Pear is the origin of the line "A dainty bit of a Warden pie," in the well-known song of the "Friar of Orders Grey."

This fine old estate is ably managed by Mr. Allis, who was formerly gardener at Hartsholme, but is much more than gardener at Old Warden.—J. WRIGHT.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 8. NEW SERIES.

CONTINUING our remarks from page 27 on the Hymenopterous order, or "order of bees," we arrive at the Anthophila. In their characteristics these bees resemble the preceding sections of Aculeata, but we at once recognise their distinctness as a group by the peculiar structure of the hind legs. The tarsus, or what we might designate by the familiar name of the "foot" of the bee, has where it joins the tibia a joint, which is enlarged and flattened into a kind of plate. In the wasps and allied genera this joint is merely rounded. Bees are evidently provided with this flattened joint—which is sometimes thickly fringed with hairs, making it then a sort of basket—to assist them in gathering and conveying pollen. But the structure occurs in some bees that do not seek for pollen. To the apiarian, if not to the ordinary naturalist, the idea of social life naturally suggests itself when bees are mentioned; it is therefore surprising to some to be told that of all our British wild bees none are really social except the humble bees. Many bees

have been supposed to live in communities when they are simply gregarious—that is, instinct leads them by scores, or perhaps by hundreds, to resort to the same wall or the same sandy bank; but each makes its nest apart from the rest, and they never unite for mutual defence or help. The first family is that of the Andrenidæ, with a short and flat tongue, and all the species are solitary, consisting of perfect males and females; being also neither beneficial nor injurious to gardening pursuits, and in their habits they remind us of the proceedings of some of the solitary wasps. The genus Colletes offers a good example of these bees. The average length in this genus is about a quarter of an inch; the thorax is downy, and the abdomen ringed with greyish hairs. The mother bee makes a burrow or tunnel in a suitable spot, frequently a sandbank, occasionally a soft wall; and at the bottom of this, which may be 9 or 10 inches deep, a cell is formed, in which an egg is placed, with a supply of honey and pollen. Another cell is added, then more, until perhaps a dozen have been completed, and the satisfied parent departs, having finished her life work. The partitions of the cells and the sides are plastered over with a gummy substance that is presumed to be secreted by the bee.

But the question may be put. Each young bee as it emerges must travel along the cells of its companions except the one nearest the top, do they all emerge simultaneously? Now, it is found that the busy mother takes some time over her operations, and therefore the first-laid eggs would be likely to be the forwardmost, yet these are farthest from the place of exit. It is believed that this difficulty is met thus: Each bee deposits eggs that produce male and females, and the latter require the longest time to reach maturity. Female eggs are therefore laid in the first-made cells, and a batch of male eggs to finish; the bees developed from these are soonest out, and leave their cells empty for their female companions to pass through. The same plan has been noticed in the genus Osmia, but how the sexes manage the emergence amongst themselves is doubtful.

In Sphecodes we have singular little bees, rather wasp-like, with red and black bodies. Their burrows are usually in dry banks, and they are often seen mixing with colonies of Halictus. These are also small and glossy like those in the genus Sphecodes, but they are downy or hairy. When these discover a suitable hole in a bank, instead of forming a long burrow they will form several short ones of two or three cells each opening into this common exit. Andrena is a genus that shows some variety of size and appearance. Some of these insects are about the dimensions of the hive bee, others are much smaller; they are all more hairy than that species. Their tunnels are of rude construction. A. hirtipes is a species notable for the very large size of the pollen brushes that adorn the tarsus of the female; the head is grey and black, the thorax black and yellow, and the abdomen black and white. The second section of the true bees contains more species than the preceding, and in this, the Apidæ, we observe that the tongue is long, and doubled under the mouth when the insect is at rest. The size varies from that of the large Bombi to that of the smaller Nomadæ (cuckoo bees), and in habit some are social, some solitary, and some parasitic. Many are visitors to our flower gardens and shrubberies, and some species have been placed on the list of "garden foes" because they form their nests in branches or in stakes. But the mischief they do in that way is only trifling, nor do they often attack wood that is entirely sound or healthy. Something may be said, too, concerning other species that are known as the "Leaf-cutters," and which, by the operation of their keen jaws, tend to disfigure various plants and shrubs. To commence with the cuckoo bees: there are five genera of these, containing probably about fifty species, and they have taken their appellation from a habit that brings them into an association with the bird whose peculiar cry suggested the popular name. Through their structure these bees are unfitted for the digging or boring operations performed by others, and they are not as a rule collectors of pollen; Nature has therefore taught them to provide for their young by artifice. Diligently and cautiously do they pursue the tracks of the Andrenidæ and Apidæ, and having discovered a burrow prepared and stored with food the parasitic or cuckoo bee enters, and deposits its egg or eggs. These produce larvæ which devour whatever honey and pollen is obtainable, and perhaps they eat also the rightful possessor of the cell. Mr. Smith, however, an observer whose opinions and statements have ever commanded respect, thinks that in numerous instances the bee which had made and stored the cell or cells in the burrow, finding that an interloper has been there, withdraws without depositing all its eggs, or possibly any; and the cuckoo bee, having placed its eggs in the stolen burrow, closes up the opening with clay. Most of these cuckoo bees, being of the family Cuculinæ, are hairless and wasp-like, banded with black, brown, and yellow.

The last family of the Aculeata and of the true bees is called Sociales, including the hive and humble bees. The humble or bumble bees, the dumbledores of some counties, are easily recognisable as a group, but the individual species are difficult to make out, owing to curious variations in size and colour. The hum of these Bombs is to most persons an agreeable sound, nor do they readily sting unless badly treated, but they can inflict a very painful wound, having a potent bag of poison. Here, by their habits, we are reminded of the economy of wasps, for humble bees consist of males, females, and workers; the nests are also, as with the wasps, started by a few females that have hibernated. There are various wild bees that render assistance towards the fertilisation of flowers by carrying pollen from plant to plant, but the Bombs claim pre-eminence in this respect, though these bees are guilty, in some circumstances, of biting a hole in the corolla of a flower. It is the habit of some of the humble bees to hide their nest in the ground, but some make it in a slight hollow of the earth, and cover it with moss or leaves. The grubs are tended and fed by the workers, and a nest contains two hundred or even three hundred cells, but no stock of honey. We may note that it is certain many of the larvæ or grubs of bees that are placed under ground are devoured by earwigs and beetles.—C.

A WEEK OUT.—No. 3.

ROYAL BOTANIC SOCIETY'S GARDENS.

ON June the 10th I visited the above Gardens, and the following plants chiefly attracted my attention. In the glass structures I noticed *Hydrangea hortensis* in 6 or 7-inch pots, the plants not being more than a foot high and bearing heads fully a foot in diameter; and *Petunias* with large double flowers, showing their great decorative value. *Araucaria Cunninghamii* was of stately proportions, its Yew-like foliage contrasting admirably with a magnificent specimen of *Seaforthia elegans*. There were a very fine *Chamaerops humilis* with noble stem and fine head of fronds; *Phoenix dactylifera* with the stem covered with *Ficus repens*. *Araucaria Cookii* was of pendant spreading habit, and *Corypha australis* also fine. In warmer quarters were *Cereus grandiflorus* with several flower buds that would expand at night, and the good old *Medinilla magnifica* in flower, and that fine Palm *Ceroxylon andicola*.

The house devoted to aquatic plants contained fine examples of *Nelumbium speciosum*, *Nymphæas*, and *Limncharis Humboldti*; and on benches were the pretty table plant *Reedia glaucescens* and *Acalypha musaica*, which is useful for a similar purpose, requiring stove treatment. *Rhododendrons* were exhibited in a large tent by Mr. Anthony Waterer and made a very interesting display, the best old and new varieties being represented. This has not been a good season for bloom, but the following were very fine—*Snowflake*, white; *Nero*, purple, finely spotted; *Michael Waterer*, crimson-spotted, very fine; *Concessum*, pink, light centre, very beautiful; *Lady Armstrong*, pale rose, much spotted, very pretty; *James Nasmyth*, lilac, blotched maroon, splendid truss; *Helen Waterer*, white centre, edged crimson; *Delicatum*, blush merging into white, spotted brown; *Caractacus*, deep crimson, extra; *Atro-sanguineum*, blood red; *Scipio*, rose, dark spot; *Nigrescens*, very dark, almost black; *Mrs. John Clutton*, the finest of all white hardy *Rhododendrons*; *Alexander Dancer*, bright rose, pale centre, very fine; the always reliable *Everestianum*, lilac, spotted and fringed; *Hogarth*, rosy scarlet; *Cruentum*, lake; *Kettledrum*, purplish crimson; *H. W. Sargent*, crimson; *Mrs. Shuttleworth*, scarlet, lighter centre, much spotted; *Mr. W. Bovill*, rosy scarlet, very attractive; *Vivian Grey*, rose, beautifully spotted; *Lady Claremont*, rosy scarlet, very much spotted; *John Waterer*, crimson, with many others, including *Fastuosum flore pleno*, with its immense trusses of bloom, and certainly should be grown by everyone. Too much praise cannot be bestowed upon *Rhododendrons*; their evergreen foliage cheers the year round, and in their season of bloom are the most showy of shrubs, besides growing as freely in the atmosphere of towns as in the country, and are not fastidious as to soil and situation, only they do not like lime and bleak exposures.

SYDENHAM.

The following day I visited the General Horticultural Company (John Wills), Melbourne Nursery, and was particularly struck with the number of plants, especially of *Dracenas*, the whole of the houses being crammed with plants of all sizes for furnishing. The roof of a large house was covered with a plant of *Stephanotis floribunda*, with a wealth of trusses of bloom for cutting, and abundance to follow; the trusses afforded by this plant in a season must be enormous, equally good results being obtained from *Jasminum grandiflorum*. Successful as have been Mr. Bause's efforts

as a hybridist with *Dracenas*, still greater results are likely to be accomplished with *Anthuriums*, the spathes being remarkably large, flat, and bright in colour. *Nepenthes* are also well done. The crowning feat of all is the effecting of a cross in Ferns; that fine *Adiantum Bausei*, being a cross between *A. trapeziforme* and *A. decorum*, partaking more of the character of the latter parent, is of great decorative value and possesses a good constitution. A houseful of *Gloxinias* in bloom was very attractive. The named sorts were eclipsed by the seedlings for size of flower (some being 4 inches across), brightness, purity of colour, and distinctness of marking, which to my taste are much more handsome than the freckled flowers of continental origin, which lack size and are as compared with the others sparse in foliage. I may like the fancy flowers, but it will not be until they are larger, have more substance, and better foliage. Mr. Bause is not only to be complimented on his success as a hybridist, but as an expert propagator and skilful cultivator, in combination with a courteous unassuming demeanour, and as free in seeking as in imparting information.

THE CRYSTAL PALACE.—I shall offer but few observations upon this well-known place of entertainment, only it may be remarked that time may be employed usefully and instructively in a visit. Grand Tree Ferns, noble Palms, and *Acacias* in stately tree forms; as seen here they bear little resemblance to cramped pot plants. Here may be seen in all its glory that fine pillar and roof-covering plant, *Ruscus androgynus*. Outside there was evidence of beds recently turved over, showing the decline of the bedding system; and this is clearly a move in the right direction, as one-half the gardens throughout the country have the lawn spoiled by cutting it up into meaningless beds. More lawn, always pleasing, meaning less beds for summer plants and more space for the display of evergreen trees and flowering shrubs, associating with the *élite* of flowering plants in natural arrangement rather than in stiff geometrical designs. The lakes greatly needed water, and the cascades were being removed, which when effected and turved over will be a great improvement. The shrubs in the groups are planted, not to present a plane surface rising up like a bank, but are so disposed as to have a fine tufted appearance, assuming for the most part their natural forms.—G. ABBEY.

CUTTING DOWN AND TRAINING PELARGONIUMS.

THIS being the season for cutting down the plants and preparing for fine specimens, we answer inquiries from "J. D., Leeds," and F. Wilson, and no doubt anticipate some others, by publishing the following notes by a highly successful cultivator.

The annexed engravings show plants from the first start in October in small pots up to a fully formed plant. Fig. 21 is a young

Fig. 21.

Fig. 22.

plant, the head of which has been taken off to form a cutting, and the buds of which are breaking into young shoots. Three shoots are produced, and those after growing to the length of 4 or 6 inches are stopped by pinching out the points, produce their lateral shoots and flower in the autumn; and after being thoroughly ripened by exposure to the full sun, are cut down as represented in fig. 22. This is what in nursery parlance is termed a young stool or bottom, and is the sort of plant which an amateur should select to grow into a nice specimen. In fig. 23 we have the same plant grown another season and cut down; and here it will be seen it has added materially to its size, and has become a really fine groundwork for a specimen plant. But to form these bottoms is not quite so easy as to write about them. Young *Pelargonium* shoots are brittle, and hence considerable care and patience are necessary to get the shoots into the requisite form. We first begin with long hooked pegs, and peg the shoots into their places a little at a time, say depressing each shoot a little every three or four days, until it gets into proper shape; always, if possible, taking advantage of the sunny part of the day and allowing the plants to be rather dry at the time. In the afternoon of a sunny day, and before watering the plants, you may take much greater liberties with the young shoots of a *Pelargonium* than would be

safe in the morning, and hence that time should always be chosen. When the plants get too large for pegs small sticks of the necessary strength are used, placing them wherever it is necessary to draw the branches to, and to avoid using many stakes a band of bast, mat, or wire is passed round below the rim of the top and made fast; a piece of fine matting or string is then tied to the various branches, and each is drawn into the position it is destined to occupy. When the branches are depressed below the level of the rim of the pot an arrangement of this kind is indispensable, and independently of that it is a very neat way of accomplishing our aim. Without a properly formed stool it is impossible to get a perfect plant, and therefore no pains must be

Fig. 23.

spared to arrange the branches properly before they get too much crowded with foliage. Sometimes branches are liable to split in the fork—that is, where they start from the parent stem, and then before attempting to train them the branches must be tied together by means of strong pieces of soft matting. Thus arranged, with perseverance and patience, the plants may be made to assume any form you please; but they must be gently handled, and hence never attempt to train a plant except when you have leisure to do so carefully and without hurry.

In fig. 24 we have the plant advanced another year, and it is

Fig. 24.

now of a size sufficiently large for all ordinary purposes. Such a stool, with proper management and if of a free-growing Fancy kind, would form a plant from 4 to 6 feet in diameter, and should produce more than a thousand trusses of flowers—a sight worth seeing, and an ample recompence for the trouble that has been taken in its formation. The stools represented in our engravings are not ideal sketches, but actual portraits of plants.

After the plants are cut down the growths may be made into cuttings, and at this period of the year there is no better plan of striking the Show varieties than by inserting the cuttings in sandy soil in the open air and in the full sun. These make stocky vigorous plants, and if the wood is well ripened very few cuttings fail to emit roots. The Fancies strike better in pots under glass.

After being cut down the plants are left in the pots to break, and are then shaken out. This shaking-out is a complete work. Every particle of soil is washed from the roots, and these are trimmed and repotted in smaller pots, throwing in a dash of silver sand as the work proceeds. These cleansed roots forthwith emit vigorous spongioles, and the older plants are made new again. The Fancies are treated in the same manner, but they are less robust and long-lasting, and in order to gain vigour they are often grafted on the Show varieties. Grafting is done at the present

time, the stock being in advance of the seions, and the grafted plants are stood on a north or shaded border until the union is completed. By that simple means vigour is imparted to tender and delicate varieties.

KITCHEN GARDEN.

Potatoes.—The appearance of this crop is being marred as regards the early and second early varieties by the disease, the tubers in many instances likewise being affected to an alarming extent, and unless the weather become fine and dry late crops can hardly fail to suffer from its ravages. As to the best course to pursue there is none so effective as lifting, but if this be done before the tubers are moderately well ripened the quality is very inferior at first, but improves greatly when the produce is carefully stored. When the skin has become firm the tubers may safely be lifted, separating the bad from the good, and those which are sound will generally remain so and improve in quality. The diseased should be removed from the ground, whilst the haulm must be cleared away and burned.

Prepare ground for the main crop of autumn-sown Onions and winter Spinach, both of which should be sown between the 6th and 10th of next month. Give the Spinach plenty of space between the rows, 18 inches is not too much, and afford an open yet sheltered situation. Sow Lettuce seed at once for affording a late supply, and lift the plants before severe weather for continuing the supply in frames after the outdoor supply is cut off. A sowing should also be made about the 6th to the 8th of next month of Brown Sugar-loaf Cos and Stanstead Park Lettuces for planting in frames to give a first early supply in spring. A sowing of Chervil made now will stand the winter without running to seed. Where winter Carrots are grown outside the present is a good time to sow the seed, the Horn or Intermediate varieties being most suitable; sow in drills about 10 inches apart. Sow Cabbage seed from the 6th to the 8th of next month for the main crop, and see that the earlier-sown plants do not lack attention in pricking-off as they become ready, as the sturdier they are kept the more surely will the plants pass the winter. Winter Radishes—Black Spanish, China Rose, and Californian Mammoth—should now be sown, and occasional sowings at intervals of the summer varieties. Another good breadth of Turnips should be sown in an exposed situation. Complete the planting of Broccolis for late use as early as possible, also autumn Broccolis and winter greens, or whatever may be most required. Continue to sow and plant-out the earliest Endive, and earth-up the earliest crop of Celery, previously supplying water liberally if necessary, and complete as soon as practicable the planting-out of late crops. Shallots, Garlic, and the earlier varieties of autumn-sown Onions should be taken up when growth has ceased, spreading the bulbs over the ground for a few days, so as to have them well dried before storing.

FRUIT HOUSES.

Vines.—Unless the foliage is very good there is some difficulty in keeping black Grapes in good condition at this season, as the sun injures the colour of the berries, therefore a little whitewash or other light shade placed on the roof lights may be advantageous in some cases. Examine the bunches for decayed berries, and keep the house dry, and as cool as possible. Vines in the earliest house will require a dry warm atmosphere to thoroughly ripen the wood, as upon this depends the production of compact well-formed bunches next season. All laterals and late growths must be kept in check, and complete rest brought about by gradually allowing the borders to become dry, but not to the extent of cracking. The late rains will have a tendency to keep early Vines growing that are planted in outside borders, to prevent which protect them from further moisture, to induce early maturity. Ventilate houses freely in which Vines of the variety Lady Downe's are planted until the Grapes commence ripening, affording sufficient fire heat at night to maintain a temperature of 70°.

Inside borders of late houses must be well attended to in watering, occasionally supplying weak guano water. No injury will result to the Grapes from watering the borders though the fruit be advanced in colour, providing it be done in the early part of the day, so as to allow the surplus moisture to be evaporated before closing time. The laterals should be kept pinched, not allowing them to become crowded and then have to remove them in quantity, giving a check often resulting in shanking. Young newly planted Vines should be kept in full growth for some time to come, maintaining a humid atmosphere and a night temperature of 65° to 70°, closing early in the afternoon, and allowing an advance to 90° or 95°.

Peaches and Nectarines.—The trees in the late succession houses must have every attention in syringing to keep the foliage free from red spider, and the inside borders must have copious waterings whenever necessary, assisting weakly trees and those heavily cropped with liquid manure. Keep the shoots tied-in as they advance in growth, and the laterals well pinched back, especially those from strong growth. Cease syringing when the fruit commences ripening, but maintain a fair amount of moisture by damping available surfaces frequently in bright weather, admitting air freely. To assist in the colouring of the fruit they should be exposed as much as possible to the influence of the sun and air by removing some of the foliage where too thickly placed, and where the fruit is on the under side of the trellis the shoots may be untied and regulated, so as to bring the fruit to the light. Trees from which the fruit has been gathered should have the bearing wood of the current year cut out, and the wood for next year's bearing where too crowded well thinned out, so as to permit sun and air to have free access to the foliage, employing the syringe freely to destroy red spider, and keep the borders moist, not allowing them to become dry.

ORCHARD HOUSE.

Some of the trees growing in pots may be placed in the open air, especially Pears and Plums, and in some instances Peaches and Nectarines, arranging them on a hard bottom and in a sheltered yet sunny situation, and plunge the pots in ashes. If it be desired to accelerate the ripening of the fruit it may be effected by closing the ventilators as early as 5 P.M. and opening them about 7 A.M. Syringing the trees should be continued every evening at the time of closing the ventilators until the fruit is ripening. Let Peach and other trees which are swelling their fruit, whether in pots or planted out, be liberally treated with surface dressings, supplying also weak liquid manure. Stop or pinch back very luxuriant shoots, and as soon as the fruit is gathered from any tree cut out all weakly growths and recommence syringing. Peach, Nectarine, and Plum trees in pots should be returned to the house for ripening their fruit unless the weather should prove unusually bright and warm; but Pears must be allowed to mature out of doors unless the weather be very wet or cold, as to return them to the house for ripening would deteriorate the flavour of the fruit.

PLANT HOUSES.

Azaleas.—The plants when placed outside must be stood upon a hard bottom impervious to worms, and the pots should be protected from the sun, otherwise the roots will be liable to injury from the heating of the sides of the pots. Slight shade will be necessary until the plants become inured to the sun's rays. A temporary awning may be employed, or, what is better, a slight framework sufficient to carry a roller and canvas covering that can be run down when the sun is powerful, or at night or other time when heavy rain threatens. Where no such contrivance can be had the plants should be laid on their sides during heavy rains, and be careful not to allow the plants to suffer by insufficient supplies of water.

Hardwooded Greenhouse Plants.—Placing these outdoors is injurious to some, whilst others are benefited. The chief of the latter are Acacias, Adenandras, Cytisuses, Correas, Dillwynias, Epacrises, Eriostemons, Chorozemas, Tetrathecas, Pultenæas, Polygalas, Pleromas, and Heaths; and although Boronias, Hedaromas, Leschenaultias, and Pimeleas will flower freely without exposure, placing them outdoors preserves them from mildew through the autumn and winter. Aphelexises, though free-flowering when not exposed and are not subject to mildew, yet retain the flowers better for a short exposure. Statices, Dracophyllums, Acrophyllums, Gompholobiums, Roellias, Witsenias, and Hoveas should not be placed in the open air.

Pelargoniums.—Early-flowered plants will be ready for cutting down, large or full-sized plants being cut back to within two or three eyes of last year's wood, young plants being allowed a couple of eyes more to each shoot, having the soil moderately dry, or the roots will suffer. The plants should be placed in a frame with the lights well tilted, syringing lightly every afternoon to induce fresh growth, affording no more water than is necessary to keep the soil moderately moist. Zonal Pelargoniums, especially the double varieties for cutting, are fine for conservatory decoration, and flower continuously with the assistance of liquid manure given weak and clear about twice a week before the soil becomes too much exhausted.

Fuchsias.—Young plants are much to be preferred to old. Shoots of free growth should be chosen during the next month and struck in gentle heat. When rooted pot-off the plants in 3 or 4-inch pots, employing good loam with a sixth each of old thoroughly decayed dung and leaf soil with a sprinkling of sand. Place the plants near the glass in a temperature of about 50° at night. In about two months shift them into 6-inch pots, and keep the plants growing well up to the light during the autumn and early winter. Any old plants that have flowered and become shabby may be rejuvenated by cutting back the growths slightly and thoroughly cleansing them of aphides, thrips, or red spider by syringing with an insecticide and removing an inch or two of the surface soil, adding new and rich compost, placing the plants in a house or pit where they can be kept close and moist by syringing morning and evening; they will start freely, showing numbers of flowers without making much wood, coming into flower in about six weeks, and if assisted with liquid manure will flower until a late period in autumn.

TRADE CATALOGUES RECEIVED.

Paul & Son, The Old Nurseries, Cheshunt, N.—*List of Strawberries.*
Ewing & Company, Norwich.—*List of Clematises and Roses.*
W. Dobbie, 62, Preston Street, Faversham.—*List of Pelargoniums and Fuchsias.*

****** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Orchids (Z. L.).—They are grown well at Burford Lodge, Dorking, the seat of Sir Trevor Lawrence, Bart., M.P., and in the leading London nurseries.

Moths (L. T. T.).—We have not received the moths to which you refer in your letter of the 25th inst.

Address (T. McKenzie & Son).—We do not know the address of the gentleman you name, nor have we seen the pamphlet to which you refer.

Index (A. C. H. O.).—The index to which you refer was published with the last number of the volume, and was, or ought to have been, sent with every copy of the issue of June 24th, and can still be had from the publisher.

Souvenir de Malmaison Carnation (C. D.).—We have had plants flowering from June onwards till October, but it is impossible for us to state from your description of the growth whether your plant will flower this season or not. If it does not it will probably produce fine flowers early next year.

Mealy Bug on Vines (J. B.).—If you read attentively what is published in the present and the last issues of the Journal you will be able to select the remedy that applies more particularly to your case. It is most difficult to eradicate this insect after it has been allowed to increase and infest the foliage and bunches.

Exhibiting Cut Flowers (North Devon).—If you have quoted the words of the schedule accurately the class is about the most unsatisfactory one that has come under our notice. No one can answer your question but the Committee who prepared the schedule. Apply to the Secretary.

Seedling Viola (J. S.).—The colour is rich but not unusual, and the flowers possess good form and substance. If the plant is of compact growth, and a free, early, and continuous bloomer, the variety is worthy of preservation; but we do not think it likely to be of substantial commercial value.

Fungus on Roses (H. E. W.).—Your Rose tree is attacked by the orange fungus. For the remedy see reply to "M. J. L.," on page 79 of our last week's

issue. *Geranium striatum* is a rare and doubtful native. It has been found in Cumberland, Cornwall, Chepstow, and near Teignmouth, in the same locality that probably you have found it—viz., Bitton Wood.

Earthing White Beet (*E. G.*).—It is a great improvement to earth up the stalks of the White Beet in the same manner as Celery when they are intended to be peeled and eaten as Seakale. No vegetable is more benefited by the application of liquid manure than the White and Brazil Beets.

Canterbury Bells not Flowering (*J. M. A.*).—The seed was not sown soon enough. It should be sown in May or early June. It is only during favourable seasons that the plants from seed sown in July flower freely the following year. Your plants, however, if they pass the winter safely, which they usually do when grown in well-drained soil and not too crowded, will make a grand display next year.

Mealy Bug on Vines (*E. D. C.*).—You will have read what is published on page 63. In your case we can only advise you to dissolve about 3 ozs. of soft soap in a gallon of water, adding to it half a pint of tobacco water, and with this sponge the leaves; 4 ozs. of nicotine soap dissolved in the same quantity of water will answer equally well. See also what is said on the subject in this week's Journal. War should be waged against this insect both during winter and spring. Some gardeners have so much work of various kinds to do that without a little extra assistance occasionally they cannot devote the time that is necessary to eradicate this most troublesome and injurious insect.

Grapes not Colouring (*A Constant Reader, Devon*).—If the foliage was injured by the bursting of the flue, and also by the application of sulphur to a too highly heated surface, that is quite sufficient to account for the present condition of the Grapes, and the heavier the crop the greater would be the defect in the ripening of the fruit. There is no remedy this year, but we should cut the Grapes as soon as possible and allow the Vines to make free growth. If you do this, and crop lightly next year, the fruit will probably ripen and colour well.

Pteris serrulata cristata (*H. H.*).—The frond you have sent is very decidedly crested, or rather tasselled. If your seedling is a good grower we think it a very ornamental variety, yet not superior to others already in cultivation. The finest form of *Pteris serrulata* that we are acquainted with is *P. s. cristata* major, which, we think, originated at Chiswick, and there are some splendid specimens there now 3 feet high and through; this variety, however, can only be increased by division, as it does not come true from spores.

Laurels versus Sweet Bay (*B. Martin*).—The common or Cherry Laurel is the *Cerasus Lauro-cerasus* of botanists, and is included in the natural order Rosaceae. The Sweet Bay is a true Laurel, and is named *Laurus nobilis*; it is very distinct from the common Laurel, being widely separated from it in all natural classificatory systems. It is included in the order Lauraceae, which also contains the Camphor and Cinnamon plants. The term Bay, therefore, cannot properly be applied to the common Laurel.

Criticism (*Old Subscriber*).—We thank you for your criticism. It is well merited, but why did you not send us your name and address? We are all liable to make oversights in the hurry of presswork. The Strawberry, it is true, was not approved by the Fruit Committee when it was exhibited in 1878; but how many fruits and flowers have had to be exhibited again and again before they received the approval that was coveted for them. You ought to know that in this last case your criticism is ill founded.

Begonia lucida (*E. D. C. T.*).—The above is the name of your Begonia; it is sometimes also called *Saundersii semperflorens*, from its continuous-flowering character. It is one of the most useful for flowering in the winter in a temperature of 55° to 60°, and is valuable for affording flowers for cutting. It is readily increased by cuttings, which spring from the base of the plants; the older flowering shoots strike freely, but seldom make good plants. It succeeds well in a greenhouse or frame during the summer.

Grapes Scorched (*F. J.*).—The Grapes on the Vine in your ground viney are seriously scorched, the result, probably, of the case having been kept closed too long in the morning, and then much air being admitted to lower the temperature. Leave the ventilators slightly open all night, admitting more air immediately the temperature commences rising in the morning. If with this treatment the scalding continues, sprinkle a little whitewash on the glass to subdue the effects of the sun. Scalding of the berries and scorching of the foliage of Vines are always most prevalent during a fitful season of cloud and sunshine suddenly alternating, and after several dull days a slight shade applied to Vines that are prone to scorching immediately the sun is again powerful is often a wise precaution; but Vines in good condition and well managed rarely require shading.

Melons Unhealthy (*Idem*).—You may well complain of the Melons not setting their fruit, and had we known the condition of the plants we should have added to our former reply. There are at a moderate computation at least five hundred aphides on the two leaves sent. You must sponge the under surface of every sound leaf at once with a solution of soft soap and tobacco water, or other approved insecticide, of the strength that has so often been recommended in these columns. Unless you destroy the insects they will speedily destroy the plants. Remove the very much injured and partly withered leaves and burn them.

Millipedes in Strawberries (*E. J. R.*).—The small "worm-like creatures" did not arrive in a condition to be carefully examined, as the Strawberry and portions of roots were very imperfectly packed. The name of the pest that is so numerous is, we think, *Julus guttatus*, which often attacks ripe fruit as well as roots. We know of no means of banishing it from gardens, but gas lime dug into the ground in the autumn and dressings of salt and soot in the spring might be beneficial.

Vegetables for Gardeners (*Ramallo*).—When a gardener is allowed vegetables from his employer's garden it is understood that he has the surplus, and we cannot understand any gardener so indiscreet as to take what is required by his employer; in fact, a gardener engaging on the above conditions virtually undertakes to grow sufficient for his employer's use and his own too, and he is fully justified in doing so. When vegetables are not mentioned in an agreement a gardener has no "right" to take them. Most employers, however, having a good man, usually allow him to have a portion of the produce that would probably otherwise be wasted; but he is not justified in "supplying himself with what he wants" without permission. It is always best to make a precise arrangement on this matter which is clearly understood by both master and man.

Grapes Scalded (*Inquirer*).—Read the replies given to other correspondents on this subject. You say nothing about the temperature provided for the

Vines and system of ventilation. If the night temperature is 70° to 65°, and you ventilate freely night and day, we can only suggest that you sprinkle the glass over the affected Vines with limewash to break the direct rays of the sun. A low night temperature followed by a great increase of sun heat before the ventilators are opened sufficiently in the morning are conducive to the scalding of the berries.

Pansy Flowers Eaten (*J. S. J.*).—The flowers are probably eaten by small snails or slugs, and if you examine the plants at night with the aid of a lantern you will no doubt catch the depredators at work, enjoying what you will take care is their last meal. By spending a little time every night in searching for the marauders you will soon reduce them considerably. We should also sprinkle soot amongst the plants, blackening the ground with it. This would check the slugs, and at the same time benefit the plants considerably by improving their growth and heightening the colours of the flowers. We are obliged by your letter, and your suggestions shall have our consideration.

Vines for Cool House (*J. T. B., Preston*).—You cannot have a better variety than the Black Hamburgh. A Vine planted at one end of the house and allowed to make all the growth possible the first year, shortened at the winter pruning to a length of 2 feet or so, this being trained along the front at the base of the rafters, and in spring one shoot being trained up the roof and another left for extension, to be shortened at the next pruning at 4 feet, again taking two shoots, one up the roof and the other for extension, and so on each year, would thus occupy the whole roof—that is, the main rod would be trained along the front, and four canes taken from it would furnish the roof. The end canes should be 2 feet from the ends of the house, and the others 4 feet apart, and the whole trained not less than 16 inches from the glass. Two Vines would, of course, furnish the roof in half the time that one would; or if you desire Grapes quickly you might plant four Vines, bearing two or three of them heavily for a year or two, then removing them, the strongest and most healthy being in the meantime allowed to extend to occupy the entire roof. This, with such short rafters, would be better than training one Vine to each rafter. Vines thus grown on the extension principle usually succeed well in ordinarily fertile garden soil mulched with manure. We will readily render you all the aid we can on your stating your requirements and conveniences explicitly; but we cannot undertake to name varieties of Zonal Pelargoniums, nor any other florists' flowers. Your plant from which the leaf is taken is perhaps *Saxifraga sarmientosa*, but the leaf was much crushed, and no flowers accompanied it, which are necessary for correct nomenclature.

Potting Cyclamens (*H. T. H.*).—The following extract from our "Greenhouse Manual" may be of service to you:—The time of starting the established plants is in the end of July, the beginning of August, or later, for after the plants have flowered, or whether they flower or not, they are kept under glass until the middle of June, and then plunged in frames or out of doors. Drying-off the roots or eorms impairs the vitality of the eorm, and destroys the majority of the roots, which are as perennial as the eorms. From the end of July they should be examined frequently to see when they begin to grow, and if the soil is dry at that time water is given. Withdraw the pots from the plunging material, take the plants to the potting bench, turn them out of the pots, remove as much of the old soil as will come away freely without injuring the roots, and repot in the same size of pot. After repotting place the plants in a cold frame, keep them close and moist for a few days, and then admit air freely. Take care not to overwater, and sprinkle overhead every afternoon on closing the frame. By the middle of September they will be growing freely; the pots will be full of roots, and the plants may be shifted into 6 or 9-inch pots, or be flowered in those in which they were first potted; in either case they may be removed to a house with a temperature of 55° at night, placing them near the glass, and admitting air freely. A stove, or any house where there is a temperature of 55° at night, is suitable. Here they may remain until they flower, when they should be removed to a house with a temperature of 45° to 50°. Two parts of light fibrous loam, one of sandy peat, one of leaf soil, and a sixth part of silver sand and small charcoal, forms a suitable compost. This manual would probably be of great use to you, and can be had from this office post free for 10d.

Insects on Vines (*J. T. S.*).—It is no trouble to us to answer inquiries when we can do so usefully to those seeking information. There happened to be no insects on the Vine leaves you sent, your letter implying that you had destroyed them; but the Melon leaves were infested with the red spider, indeed we have seldom seen a worse case. The insects on the Vines you say are the same as on the Melons. We have no doubt they are, and we are quite certain those on the Melons are red spiders. Your description of them as seen through a microscope quite confirms this, though you appear to think it does not. When the red spider is young it is a pale greenish red; it then changes to a bright red and is very active in its movements, but when it becomes old it is just the colour you describe, and moves as you say, slowly. The insects you examined were old; on the Melon leaves we found the red spider insects in all stages of growth. As we gathered from your former letter that you had destroyed the insects on the Vines, of which the leaves sent appeared to afford proof, we advised you, for another reason, not to syringe; we now advise you, however, as the Vines appear yet infested, to give them a thorough washing, directing the water as forcibly as possible to every leaf. Five or six gallons applied to a full grown Vine will not be too much, in fact you cannot wash them too thoroughly. Choose the early morning of what is likely to be a dry but not a very bright day for the washing, and then throw wide open all the ventilators to dry off the moisture, much of which you can remove by shaking the Vines. A syringing like this once a week will be a great benefit by washing off most or all of the insects. In the meantime ventilate very freely. We repeat, the warts on the leaves are not caused by either insects or fungus, but are the result of injudicious treatment. The leaves afforded us clear and unmistakable evidence on that point. Your Melons, which have been much neglected, are, we fear, beyond cure, but the Vines are far from hopeless.

Names of Fruit (*E. D. C. T.*).—It is the Kentish or pie Cherry.

Names of Plants (*Miss Briscoe*).—The long leaf is that of a weed, a species of *Doek*, which has come up in the soil in which the *Calceolaria* seed was sown, and which appears not to have grown. The berried plant is *Solanum nigrum*, also a weed. (*J. T. B., Preston*).—We do not undertake the naming of varieties of Pelargoniums, and if we did, you afforded us no means of doing so, as nothing arrived but a number of loose petals. (*H. E. White*).—*Epilobium angustifolium*. (*H. W.*).—Both specimens were completely withered and unrecognisable. (*A. Boyle*).—*Lysimachia vulgaris*. (*D. W. B.*).—*Lysimachia vulgaris*. (*W. M.*).—*Cattleya intermedia*. (*S. G.*).—1, *Veronica spicata*; 2, *Dietamnus Fraxinella*; 3, *Funkia ovata*; 4, *Helichrysum argenteum*; 5, *Lysimachia vulgaris*; 6, *Epilobium angustifolium*. (*W. Begbie*).—1, *Scabiosa columbaria*; 2, *Ononis arvensis*. (*W. H. Myers*).—1, *Lychnis chalcidonica*; 2, *Veronica spicata*; 3, *Sedum ibericum*; 4, *Sedum neglectum*; 5, *Oenothera taraxacifolia*; 6, *Spiraea Filipendula flore-pleno*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE ADVANTAGES OF AUTUMN CULTIVATION.

THIS is one of the most important subjects connected with agriculture. It is, however, generally identified with cleaning the stubbles after crops of corn and pulse. By attending to this matter the home farmer will be enabled to cultivate the land under his management to the best advantage, and with a quicker succession and rotation of crops. Although it is called autumn cultivation, yet it is practically the commencement of the agricultural year, for it is after the harvest has been gathered-in that autumn cultivation really commences. The theory on which this early tillage is advocated is that couch grass and other root weeds as soon as the crops are cleared after harvest are really at the weakest, not having extended their roots much below the surface. As soon, however, as the crops are removed, if the couch, &c., is allowed to remain undisturbed it spreads rapidly both above and beneath the surface of the ground. In case the cultivation is deferred altogether until the winter or spring it gives the farmer infinitely more labour at the busy period; sometimes the fallowing process may be prevented entirely, or the season for sowing root seeds or early Lent corn will be so far delayed as to greatly diminish the prospect of good crops. The advantage of this early preparation is enhanced by the certain benefit of but little work being required in the spring; in fact, the ground not being deprived of its moisture, all seeds sown at that season will be sure to vegetate immediately.

There is certainly no more important operation in agriculture than eradicating couch and weeds, for we cannot expect to grow full crops on foul land. Weeds are the most insidious enemies of farming, for it is common amongst farmers in speaking of couch grass to say there is so little in such a field that it will not injure our next crop, thus forgetting that whilst the corn may be growing the grass and weeds are daily increasing. The only way to successfully overcome the weeds is to attack them in their infancy, and this brings us to the consideration of the first and best means of commencing operations against them. Let us, for example, take a Wheat stubble which is intended to be sown with the seeds of Rye, Vetches, Trifolium, or any green crops for food of stock in the spring. We recommend the home farmer to select for this purpose the cleanest stubble on the farm, so that no grass, &c., may interfere with the growth of the fodder crops, but that when the green crops are removed the land may be sufficiently clean to be ploughed and sown for root crops immediately, as there is then no time to clean the land without losing the proper seeding or planting time. Now, in order that the land may really be clean enough to receive the seed of fodder crops upon nearly all the mixed soils, and especially after wheat sown on a clover lea, there will usually be more or less of bunches of couch or onion grass, either of which should be forked out. This operation, which is usually done by women, can be carried out at a cost varying from 3s. to 6s. per acre, after which the weeds should be removed to a heap; the land will then only require to be once ploughed before seeding to green crops, and no time will be lost before sowing the seed.

The next thing to be considered is the treatment of stubble land intended for Lent corn or pulse in the following spring. We must, however, take it up in two divisions—the treatment for light and dry soils first, and secondly for heavy and strong soils. In the

former we find couch and other weeds the roots of which dive into the soil a considerable depth; in this case, whether we cultivate by horse labour or by steam power, we must till deeply and not to leave the grass under. In fact in all autumn culture of this kind, and with this object in view, steam power is best, simply because it can be done in the least time, and we cannot prolong the time, as we can only reduce the labour into the shortest possible period by steam culture. The first operation, then, is to cultivate with the points as deep as the land has been ploughed on former occasions, and as soon as the steam cultivator has been over the land one way we advise taking it over the second time across the first work. The land will then lie rough, or at least the clods and bunches of grasses will lie sufficiently loose and on the top to be treated by horse or ox labour with Howard's patent self-lifting drag. The ring roller may then be used, but not until the couch is entirely brought to the surface, and to this point the attention of the home farmer must be carefully directed. Then should succeed as many draggings and rollings as will enable the chain harrow to operate in collecting the grass and root weeds into heaps or rows, and in case the weather should be dry enough burn the weeds in small heaps, and spread the ashes. However, should the weather be showery and uncertain there must be no delay, because the couch must then be carted away to heap or otherwise disposed of, in order that the drag may be employed again, so that all the couch remaining should be combed out and disposed of to render the land clean enough to be winter-ploughed after the Wheat seed time is over. It must, however, be remembered that in extremely foul land it may be requisite after the first crop of couch has been removed to steam cultivate as at first, and again follow by dragging, rolling, &c., and the couch being again disposed of either by burning or carting to heap. We like the carting away to heap, because it is a rule we recommend in agriculture never to burn anything which will decay unless we actually need ashes for drilling purposes. Couch when drawn off to heap or laid out on pasture land for manure never requires so much labour besides the carting, as it does for the burning; therefore time as well as labour is saved, besides being comparatively independent of the weather during the work of removal.

The above remarks apply chiefly to dry chalk, gravel, or sand, and the varieties of friable loams; but we must now refer to tillage of heavy loams or clay soils. In doing so we will again take a Wheat stubble, and as upon the generality of such land the white-rooted couch does not prevail; but we find chiefly the fine running grass, which spreads over the surface only, and is commonly called water grass, and where this predominates the deep moving of the land as a first operation is not necessary; therefore Coleman's scarifier with shares on—if worked about 2 inches in depth, or as shallow as will move the surface of the land at a regular depth—will be sufficient to cut the small fibrous roots of the running grass, after which it may be dragged with Howard's implement, before referred to. The ordinary iron harrows will also loosen the grass from the land, and it may then be treated and collected with the chain harrow, so that the grass and other weeds may be either burned or carted away as may be most convenient, after which it will require careful examination to observe whether any grass is left, in which case the former work must be repeated. There will still be another matter to be noticed, for in the case of small ridges and deep land furrows some grass will be found in them; we then advise the use of the double mould plough with a new cutting share, which will reach all the grass in the furrows, and will be lifted out by the double turn furrows on either side, and then by using the harrows lengthways with the furrows the grass will be brought to the surface free from the earth, and may be collected by the use of the chain harrow.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Work of every kind that can be done by the horses in anticipation of the harvest should now be attended to, so that as little as possible of the necessary work may be left undone at the time of harvest. It may now in most instances be decided whether the produce of certain fields either of Wheat, Barley, Oats, Peas, and including the second crop of Clover hay, shall be stacked in the field where grown or carted to the barns or rickyard. The materials for making the stands for them may be carted to the spot required, such as bawns, and also the straw for thatching. If more is wanted of either material than is produced upon the farm it should be purchased and got home, and placed ready for use, in order that the horse labour so valuable at all times may be economised, and not displaced at the busy period. If it is intended to sow Turnips in the stubbles after cereal crops or pulse, such as winter Beans, Peas, Vetches, &c., both seed and manure should be obtained and prepared for use at short notice. The latter, whether of dissolved bones, superphosphate, or other artificial dressing, should be placed in the manure house mixed with ashes, &c., ready for use when required. In the case of the Turnip seed being drilled it should be done every day as fast as the corn is cut, and the seed with manure drilled whilst the land is soft, moist, and kind, which is the important point in growing stubble Turnips, and this may be done upon two-thirds of the land, and then finish the remaining third after the corn is carted. Where there is any land to be seeded to permanent pasture it should be ready to receive the grass seed about the middle of August, because we find if sown much before that date the weeds are apt to overpower the young grass plants. Whatever seeds are selected it is best to sow the heavy seeds, such as Clover, separate from the light seeds, such as the pasture grass seeds. Unless the land has been previously manured it is best to sow artificial manures in a finely divided state, and we recommend 4 cwt. per acre of bone superphosphate to be sown and harrowed-in with the seeds, because if ammoniacal manures are required it should be sown the next year, otherwise the weeds are too much encouraged if sown with the seed. The second cutting of broad Clover will soon be ready for hay; it is, however, frequently folded off with sheep; but we prefer cutting for hay, or seed, or for soiling cattle, as we find that more Wheat can be grown when cut twice or thrice than when the lattermath is fed off by sheep. This is accounted for chiefly by the extra growth and weight of Clover roots attained, these roots being found to afford great nourishment to the following Wheat crop. The sowing of Turnips after green crops will still be continued with the chance of a fair crop of a quick-growing variety like the Grey Stone, but we prefer planting or ploughing under furrow good strong plants of the Thousand-headed Kale. These will be sure to live and thrive to a much greater certainty, and come fit for feeding much quicker than Turnips sown late. It is, however, expensive to purchase the plants, but we called the attention of the home farmer in the spring to the advantage of growing seeds for his own use of all kinds of Cabbage, Kale, Rape, Broccoli, &c., for he will always find it answer his purpose, as there is sure to be a ready sale for any plants which he may not require if the seed sown was of the best kinds.

Hand Labour.—This has been greatly economised by the use of labour-saving machinery, even at the busy period of haymaking in the park land, pastures, and meadows. The working of the mowing and tedding machines has very much curtailed the time and cost of the work, except in the water meadows flooded by the ridge-and-furrow system where the scythe is still required owing to the uneven surface; but upon catch meadows the mowing machine can be employed again at the time of carting. The horse rake to gather the hay is a saving; and at the rick, instead of the heavy lifting labour in passing the hay from the waggon or cart to the stack, the elevator as lately improved is an immense saving of hand labour. Men will still be required in hoeing root crops both by cutting up the weeds and singling the plants, the cutting of Peas, winter Oats, Canadian Oats, and winter Barley, as well as Rye, as these will all be fit in a few days, and should each in their turn have the attention of the home farmer, and should be cut rather green with the view of not only saving the most grain, but with the advantage of a better feeding value in the straw and haulm of the different crops. The shepherds should now pay attention to the ewes both of Hants and Dorset downs, and if in good order and condition they will offer to the ram early, so as to bring their lambs soon enough to be fattened for the Easter markets, or held on as superior animals for exhibition at the first cattle shows next year. The ewes will generally offer early with a constant change from Saintfoin at day to a folding of Rape at night time. A few cracked Beans, however, will be of great service to them, but as soon as the ewes have been served they may be drafted from the main flock and fed with rather less cost. The home farmer should now secure a well-bred yearling off bull to run with the heifers of the same age, so that the calves may fall as soon as the early grass is ready for the cows in milk. All the young lambs, whether of ewes for stock or wethers for grazing, should be shorn about the first week in August, because they always winter better, as their wool will be firm and reject the rains of winter. When not shorn the sooner they are dipped the better to prevent the fly from striking, but this operation requires great care and attention by the farmer, for we have known serious losses when men unaccustomed to the work have been employed. The dairy cows after the recent rains will be doing better, for they have made but poor returns in milk,

butter, or cheese, the months of April and May having been so dry and harsh, and much against the growth of grass on the pastures. Breeding sows should be kept in a roomy well-littered yard, and besides trough food, should get a liberal supply of green fodder. Rice meal is now cheap feeding, and well adapted for trough food in part.

KERRY COWS—SELECTION AND BREEDING.

LIKE all other breeds of cattle there are degrees of excellence among the Kerrys. Good, better, best are pleasant and possible gradations among them, the two first already being within our grasp, but the higher and most desirable stage has yet to be attained, as it undoubtedly will be in due course. An abundant yield of milk, rich as an Alderney's, a plump and sleek condition, hardiness, small size, and a moderate consumption of food in comparison with that of larger animals, great gentleness and docility, are merits possessed more or less by all Kerrys that I have seen. Keeping these points in view, it is reasonable to suppose that by careful selection the breeder may hope to obtain a herd of cows all up to a given standard of excellence.

Now, it is for the dairy that this breed is unquestionably most valuable, notwithstanding the fact of the beef commanding a higher price than any other in the Dublin market, and it is therefore from the best milkers that we must hope to obtain a select and pure strain, and not by the indiscriminate purchase of any cows imported from the mountains of Kerry. In the first instance recourse was had to imported cattle, and it is from such that the Streame herd sprang. Of the degree of excellence to which this herd has already been brought "D., Deal's" note on page 18 bears witness. I have not yet been able to obtain a cow equal to Dr. Hogg's famous one which gives twelve quarts of milk daily, or Mr. Robertson's still better cow, which was giving sixteen quarts a day last August at La Mancha; but amongst those had from Streame for the home farm here the smallest and best is Daisy just entering her fourth year. She had her second calf in May, and now gives eleven quarts of milk daily. As a heifer this cow was so full of promise that I regretted her first calf was a bull; this year she has a cow calf, a strong healthy well-shaped animal by a pure Kerry bull, and will I hope eventually prove to combine the good milking properties of one parent with the vigorous kindly condition of the other.

The development of the good points in a particular breed of cattle is not an uncertain process; repeatedly has it been demonstrated that natural functions may be brought to and sustained in an abnormal condition. The Shorthorns show this in a remarkable degree, and a glance tells the practitioner whether a particular herd has been bred solely for the production of milk or of beef, or for the best combination of both qualities. Originally Shorthorns were all deep milkers, but now most of the pedigree herds have been so much bred away from milk that the cows are often found not to yield enough milk to rear their own calves. Among breeders of Shorthorns prize beasts have been so much the rage that what may be termed showyard points of excellence have taken the lead of all others—wrongfully as I think. Aptitude to lay on flesh and early ripeness for the butcher, a square-built frame laden with fat and flesh, fore-quarters as wide and massive as the hind, all point to the production of beef at the expense of milk. But then this very numerous and important class of cattle breeders are very apt to pooh-pooh any idea of a dairy. "No milk pails for me," said a breeder of Sussex stock to me once; "I like my steers to be worth £20 at twenty months, and they require every drop of the mother's milk to give them the necessary start."

Naturally the full flow of milk in any cow is of very brief duration, artificially it has been extended almost at will. Careful selection extending through several generations is, however, necessary to fully develop this valuable capacity. In doing it let especial care be taken not to proceed to such lengths as to altogether sacrifice flesh for the produce of milk. In writing this paper I have specially kept the home farmer and his requirements in view. I am a home farmer myself, and in filling any vacancies that occur in the herd of cows kept here for the dairy supply of a large establishment, especial care is taken to select animals likely to give rich milk abundantly and yet fatten readily when done with. I once tried Alderneys, but have done with them. An Alderney eight or nine years old is little better than "a bag of bones." Now the Kerrys give milk rich as the Alderneys, and are always in a sleek condition, most of them having frames of that happy medium between the typical square-built beefy Shorthorn and the typical wedge-shaped milky Ayrshire. Taken in comparison with such huge animals they may be termed models in miniature. Is it this smallness of size that

leads authorities on dairy farming so often to speak of them as something worthy of good-natured notice, but unworthy to be classified with the Jerseys, Shorthorns, and Ayrshires? Granting that Kerrys are not admissible into large herds kept upon rich land for the production of milk for market or for cheese, yet there are great numbers of farms, notably upon poor soils, where a decided and clear advantage would attend the substitution of Kerrys for larger cows often yielding milk inferior both in quantity and quality. The advantage becomes still more striking when it is found that the food required for the sustenance of two large cows yielding together twenty quarts of milk daily will suffice to maintain in better condition three Kerrys yielding from thirty to thirty-three quarts.—EDWARD LUCKHURST.

MANAGEMENT OF POULTRY IN SUMMER.

It is some time since we gave some hints on the management of poultry in spring. Since then summer has come, alas! is passing, and summer has its special cares in the poultry yard. It has often struck us, as the time comes when we begin regretfully to watch the shortening days and the lengthening shadows, that there is some slight consolation in looking at the rapid growth and vigorous development of our young poultry—the hope of the year to come. Thus far the summer has been a favourable one, especially for young stock. We have always found our own thrive well in summers which are showery without being immoderately wet. In very dry seasons the growth of chickens is checked and disease often makes its appearance; the reason of this is manifest—the supply of insect food, so necessary for the natural development of young birds, fails in dry ground, and the ground itself is apt to become tainted. Gentle rains supply the former desideratum, and at the same time purify the soil.

We will speak separately of the treatment of old and young birds. The breeding pens should now, if possible, be separated. Where accommodation is good the breeding cocks should be put into small runs away from the hens; they will moult better in such places, or each one may run with a lot of cockerels and will keep them in order. The hens may be placed together in large batches either at liberty or in large runs. There is one great advantage in this separation—many valuable birds will continue laying. Eggs are now plentiful, and so it is often necessary to send them to market. If the hens are thus widowed there will be no fear of valuable eggs being eaten, or at least of their hatching. Where accommodation is very small of course the best must be made of it. We believe it is often a good plan to take away a cock from the general stock at this season, even if he has to be shut up in a small house, so long as it is clean and dry. We have before stated that if it is specially desired to make hens moult early they should be left two or three weeks upon sham eggs whenever they become broody in the late summer. If, however, this is done too early the moult is sometimes a spurious one, and is followed by a second moult late in the autumn, just when we wish our exhibition birds to be in full plumage.

The young stock, too, now require attention. All should be plentifully supplied with spring water. Too often only a glance is given to see that the pans are full, and full they are pretty sure to be after such heavy thunderstorms as we have had. But rain water will not do; delicate chickens invariably get gapes from drinking it, and older ones often the seeds of disease. The water vessels must frequently be well scrubbed out and filled twice daily with pure spring water; they should, too, be put in the shade. Heated water gives no more refreshment to birds than to human beings. Then it is of the utmost importance that chickens should not be crowded; even where premises are large and there is an extensive range they will not grow well if many are kept together, they congregate and taint particular pieces of ground. Constant thinning is absolutely necessary. Where poultry are only kept for the table of course the necessary killing-off of those required makes room for their successors; but where they are reared for fancy or with a view to exhibition somewhat ruthless weedings must from time to time take place. We have always found our own do best in years when we have, however reluctantly, sacrificed all but the most promising chickens during the summer months. Young birds which are strong and healthy but which fail merely in fancy points will often fetch fair prices for the improvement of farmyard stock, we mean in the case of such varieties as Dorkings, Brahmas, and others which are well known as profitable stock for their special purposes. If, however, purchasers do not come forward we advise that the birds be eaten rather than the yards should be left overcrowded.

In the matter of food we now find three good meals a day plenty; at this season meat is to be picked up by birds with even a moderate run, and the exhaustion of the system from cold is at its minimum. We are convinced that half-grown birds which are

moderately but regularly fed become eventually finer specimens than those which are perpetually crammed and stimulated. As a general rule where space is abundant cockerels and pullets, at least earliest, should long ere this have been separated. Much judgment, however, is necessary in carrying out this rule, and we have observed many cases in which birds have been thrown back and harm done by its universal and indiscriminating application. Poultry are gregarious, and we have often seen two or three fine growing young cockerels when taken away from the brood penned up alone, pine and absolutely go back in size for weeks. When too early pairs of chickens are required for exhibition we leave the sexes together, they are then used to each other and tamed quietly; if, on the other hand, a freshly caught cockerel is penned with a pullet he has never seen before a skirmish is sure to result. We have come to the conclusion that this question of separating the sexes, and when the separation should be made, is one that can only be answered after much experience and with the view to each particular case. In our opinion it is better to keep them both together, quiet and contented on a large run, than to take them off such and confine them in small places. One caution remains to be given—Never if possible let a lot of half-grown cockerels run with the old breeding stock.—C.

VARIETIES.

THE DAIRY FARMING INDUSTRY.—We cite the following from a lecture recently delivered by Professor Sheldon. It is computed that the dairy cows of these islands each yield on an average about 440 gallons of milk per annum, and this is making due allowance for inferior milkers and for stirks and heifers, whose yield of milk is generally smaller than that of fully matured cows. Now, if we base our estimate on a minimum number of 3,700,000 cows in milk—and this is making due allowance for deaths and abortive milkers—we have an annual production of 1628 million gallons, which valued at 7d. a gallon is worth upwards of forty-seven millions sterling a year. I assess the milk production of the country at this price, because it is probably the extent of what it realises to the farmer. But in any case the interests involved in dairy farming in this country are enormous, even if we confine our estimate to milk production alone; and if we include the other interests, such as the sale of surplus stock, we may conclude that the annual income to British agriculture from dairy farming is not much less than that which flows into the coffers of the Chancellor of the Exchequer. The present value of the bovine stock of these islands may be set down at upwards of 120 millions sterling. Farmers' capital employed in bucolic agriculture may be assessed at 150 millions in the aggregate, and landlords' capital at 900 millions, making a total of upwards of one thousand millions of capital embarked directly or indirectly in dairy farming in these little specks in the ocean.

— **NATURAL GRASSES.**—We have received from Messrs. Little and Ballantyne, Carlisle, a treatise on the natural Grasses, which contains some terse and useful information in relation to the culture of Grasses. The principal part of the treatise is, however, devoted to tables of the Grasses suited to different soils and situations.

— **THE TURBIT CLUB.**—We have received a new list of the Turbit Club, from which we see that the Club now numbers thirty members. Among the rules of the Club we observe that "Members be requested not to show Turbits at any exhibition which, in the opinion of the Club, does not offer satisfactory Turbit classification. We understand that at a Show to be held at Bingley on September 1st, classification approved by the Club will be given to this beautiful variety of Pigeons.

— **THE AMERICAN HARVEST.**—According to the American papers just to hand, which have been collecting reports from all parts of the States, the yield of grain for the present year will in all probability be greater than has ever been known before on the other side of the Atlantic.

— **HARVEST PROSPECTS AND THE GRAIN TRADE.**—The prospects of good harvests at home and abroad have reduced the price of corn. The average price of Wheat last week was 43s. 6d. per quarter, or lower than it has been during any corresponding week for some years. The price of Barley last week was 27s. 1d. per quarter, or lower on an average by several shillings than it has been for a very long time.

— CROP PROSPECTS.—In some places (says the *Agricultural Gazette*) the grain crops are quite as bad as they were last year, and when this is the case the prospect to the farmers must be blank indeed. Much must depend upon the weather, and certainly for some days past the sun has done his duty, and vegetation has developed with tropical rapidity. The yield will probably be good, and when there is plenty of straw there will be plenty of corn. On the other hand, over very extensive tracts the crops are thin on the ground, and cannot yield an average return, however favourable the circumstances. We shall probably have one of the finest Potato crops on record. The wet came at the right time, and if, as is probable, we are favoured with a fine time during the next two months, we shall not suffer from the blight. The quality and the size of tubers now being dug are exceptionally fine, and indicate a large crop. We never remember to have seen Potato fields and gardens looking more luxuriant than they do at present. Mangold is almost an universal failure. A large acreage was ploughed up and is now devoted to Swedes. The prospects of winter keep are on the whole good, and root land is cleaner than it has been for some years past. The good prospect of winter keep will tend to make stock sheep dearer. Lambs already feel the upward tendency, and other descriptions of stock will follow.

— ESSEX BEE-KEEPERS' ASSOCIATION.—A Bee-keepers' Association for Essex has been formed under the presidency of the Earl of Rosslyn. Depôts will be established in the principal towns of the county, where cottagers will be able to purchase all the newest and most approved appliances at a very cheap rate, and shows will be held and lectures delivered under the auspices of the Society at various places. There has been a great increase in bee-keeping throughout the United Kingdom during the past seven years, and where cwts. of honey were produced ten years ago tons are now gathered-in and sent to market.

NEW AND OLD COMBS.

"I WANT to buy a stock of bees—a first swarm of last year." This oft-expressed desire implies that young combs are better than old combs. The best time for changing hives and getting them filled with new combs is the swarming season, say from the beginning of May till the middle of July; but this work can be well done at a later period of the season, though with less advantage and a little extra trouble. In some seasons bees yield no harvests of honey, and not unseldom many hives beyond the ordinary number for the apiary are worth more to preserve for stock than to destroy for honey. Last year bees did not swarm well, and generally speaking did not yield a harvest of honey. Many hives with old combs were kept for stock with the hope that this, the present, would be a honey season, and see the apiary swept clean out of old combs. In Cheshire this season so far has been unfavourable for bees, though better than last. We usually condemn almost all hives with combs two years old. Last year this sentence was not carried into execution, and some hives in my garden have combs three years old, but the executioner is at hand to carry out the law. Most of my bees have swarmed this year, and some of the hives have yielded two swarms. A few of the weaker with old combs in them are ready to produce swarms now. All will be made to swarm, and all the old combs will be destroyed. The first three hives already dealt with produced swarms twice this season, and a "turn-out" from each was obtained at the end of three weeks from first swarming. Thus we have nine swarms from the three stocks, combs of which have been destroyed, and which in their destruction yielded honey which has been sold at 1s. 6d. per lb.—32s. in all. The nine swarms have not yet 2 lbs. of sugar each, and some of them have their hives nearly filled with combs. All the black-combed hives have been or will be treated in the same way. One swarm and a turn-out only will be taken from each of the later swarmers, and perhaps the honey of the stocks will realise money enough to feed the swarms into excellent stocks if the weather render feeding necessary. The reader will see at once that my object is not immediate profit, but the filling of the apiary with good and unobjectionable stocks containing young combs and queens. This practice and process of renewing combs and obtaining young queens is simple and intelligible—a little assistance in adverse seasons and circumstances.

The process may be strongly recommended to those who wish to change their bees from one kind of hives to another. The practice of shifting combs as well as bees from one hive to another is a bad one and should not be followed. Artificial comb founda-

tions may be employed with advantage if made of pure wax, but old or second-hand combs should not be introduced to hives of any kind, seeing that sugar is so cheap, and knowing that bees can rapidly build combs from sugar syrup. In young combs bees thrive and breed better than they do in old ones. In good seasons for honey swarms that build their own combs rise to the greatest weights. In young combs foul brood is rare, if ever found. In young combs honey is less soiled and pollenised, more easily taken—better every way.

In honey seasons when hives rise in weight beyond 60 lbs.—some beyond 100 lbs.—we drive the bees out of them in September into empty hives and feed them into stocks. In such seasons the hives yield a great harvest of honey, and their bees are sugar-fed into excellent stocks, which in no remembered instance have disappointed us. Weather and seasons may disappoint the bee-master, but his bees if properly managed will in sunshiny weather return good measure pressed down for all the attentions they may receive.—A. PETTIGREW.

EXPERIENCES WITH COMB FOUNDATION.

MUCH that has been written of late, and by some of those who are recognised as authorities in apian matters, has had a tendency to shake the confidence of bee-keepers who wish to keep pace with the march of improvement in our pleasant and profitable science. I refer to the use of comb foundations, properly so called, not mere guides. On the one hand we have some authoritatively stating, as from experience, the almost certainty of failure if any depth beyond 1½ or 2 inches be used; on the other we have masters of the science whose experiments suggest at least the probability of disaster if certain ingenious appliances, such as wires, thread, or wooden bases, be not used to render the use of large sheets of foundation safe. Now as your old correspondent "B. & W." has given in your last issue the results of his "considerable experience with comb foundation for the last three seasons," I trust you will allow me to give mine for the same period, and I venture to think my experience not inconsiderable.

My number of Langstroth hives has been from twenty to thirty—at present thirty-two; the frames 17½ by 8½, and ten frames to each box. Before 1878 I was infected with the idea, of which I would fain cure "B. & W.," that anything beyond 2 inches would be dangerous, and for seven previous years I limited my bee help to that extent only, not indeed with invariable success as to straight combs, but with the invariable production of superabundance of drones, with proportionately diminished produce of more desirable supers. In 1878 I had my first trial with deeper foundations. Mr. Raitt had then imported his first machine, which turned out sheets 4½ inches deep. Determined to give it a fair trial, I ordered 12 lbs., which contained upwards of a hundred sheets, and I considered it the best investment I ever made; two-thirds of the weight were thin for supers; and in six weeks, the whole period that season of honey-gathering weather, I took upwards of 900 lbs. of super comb honey. I bore testimony to the value of foundation in an autumn number of the "British Bee Journal" of that year. In 1879 Mr. Raitt had procured his larger machine, and I ordered a large supply of foundations 16 by 8½. The sheets were so thin that it was with no slight apprehension I began to use them, but in the issue with even a better result than my experience of 1878 as to the safety of trusting foundation pure and simple, for in that year I had one breakdown and not one since, nor a crooked comb, nor a curled corner, although the numbers used by me up to this must far exceed two hundred, as my purchases have reached nearly 40 lbs. This season a freak of my bees, unique in my experience, enabled me to put foundation to as severe a test as it is ever likely to be subjected to. Last month, one day two swarms arose simultaneously and pitched together on one tree, forming a very large swarm. I had scarcely hived them in a large skep when a third swarm out of a 20-inch skep rose and settled on the spot from which I had shaken the other two. I hived it and placed it about 2 feet from the other under the tree to let the stragglers be gathered in, but when I came to remove them in the evening I found the first skep tenantless, and the whole three swarms in one hive, making a weight of bees but a few ounces under 14 lbs. This huge swarm I put into a Langstroth ten-frame box furnished with six sheets of foundation and four perfected combs, and for results I had in forty-eight hours the six nearly as perfect combs as the four, without a wave or curl. Next day I without hesitation gave to a strong swarm nine frames foundation and one comb for immediate convenience of the queen, and with like success. Having had such experience in the use of this invaluable auxiliary to successful bee-keeping, I have felt naturally impatient that your correspon-

dents should throw out ideas calculated to prevent its more general adoption.—GEORGE A. PROCTER, *Rector of Tullamelan*.

MR. RAITT of Blairgowrie, on page 62, invites bee-keepers to state their experience with comb foundation. I have used the comb foundations made by Mr. Raitt and supplied to me by Mr. Abbott for two seasons, and I can confidently recommend it to all intelligent bee-keepers, but I cannot advise them to follow in the footsteps of Mr. Pettigrew. I have used some hundreds of sections fitted with strips of foundation, and I think in only one instance have I found the foundation fallen down; that was owing no doubt to the melted wax being too cold to adhere firmly to the wood. I certainly was very much surprised on reading Mr. Pettigrew's experience with foundations to think that he should have commenced in such a cart-before-the-horse style, by which no one could hope to succeed.—P. SKINNER, *Swanley*.

BRITISH BEE-KEEPERS' ASSOCIATION'S SHOW.

THE sixth annual Show of this Association is now being held at the Royal Horticultural Gardens, South Kensington, and will be continued until Tuesday, August 2nd. Our general analysis must be reserved until next issue; suffice it now to say that progress marks the whole Exhibition, while even those who are not novices in bee-keeping still wonder that so much room is found for ingenuity and inventiveness in winning the little busy bees into doing the will of their masters while they are made to believe they are doing their own. The exhibits of honey are large and beautiful, and when we remember the grand supers the Chairman of the Committee exhibited in 1874, and compare them with the quality of the exhibits of many even in the cottager class now, we are impressed with the fact that the Association has not existed in vain. It is not too much to say that the average of the sections of honey in the collection far surpass in quality and appearance the best of those sent to us across the Atlantic. The present year has been favourable for honey, and has clearly shown that our bee-keepers are rapidly learning not only how to manage bees so as to secure surplus, but also how to secure that surplus in the most inviting form. Foreign comb honey of course suffers in appearance in the transit; but even making allowance for this, we think the present Show proves conclusively that the home-grown article need fear no competition. The Hon. Secretary, the Rev. Herbert Peel, so organised the whole Show that everything fell into its proper place, and the bee tent with its displays and lectures is as attractive as ever.

The Conversazione was held on the evening of Tuesday in the conservatory, when the subject of the relations of bees to flowers was opened by Mr. Cheshire, who is also delivering a course of lectures on bees and bee-keeping at the gardens. The next lectures will take place at 3.30, on the afternoons of August 10th and 24th.

The following is the prize list:—

HIVES AND BEES.—For the Best Frame Hive.—1, W. Hunt. 2, W. Martin. For the Best Stock of Ligurian Bees.—1, S. J. Baldwin. 2, Neighbour & Son. For the Best Stock of Cyprian Bees.—1, Abbott Bros. For the Best Stock of other Foreign Bees.—1, Neighbour & Son. 2, Abbott Bros. For the Best Hive for Observation Purposes.—1, Abbott Bros. 2, R. Scott. For the Best Comb Hive.—1, Neighbour and Son. 2, Abbott Bros. 3, W. Hollands. c, J. Clapp. For the Best Frame Hive, Price not to exceed 15s.—1, Green & Sons. 2, J. M. Hooker. 3, S. J. Baldwin. c, W. Hollands. For the most Economical Hive, on the Movable Comb Principle, for Cottagers' use. Price not to exceed 10s. 6d.—1, Green & Sons. 2, R. McGregor. 3, W. Hollands. c, H. Parson. For the Best Straw Hive for Depriving Purposes, Price not to exceed 5s.—1, T. Sells. For the Best Supers for Harvesting Honey in the Comb in a Suitable Form.—1, Green & Sons. 2, J. M. Hooker. 3, J. Clapp.

HONEY.—For the Best Exhibition of Super Honey from one Apiary.—1, W. E. Warren. 2, S. Thorne. 3, Rev. E. Bartrum. For the Best Super of Honey. The Super to be of Wood, Straw, or of Wood in combination with Glass or Straw.—1, S. Thorne. 2, W. E. Bacon. 3, W. H. Dunman. 4, Rev. E. Bartrum. 5 and c, Mrs. Leigh Spencer. For the Best Glass Super of Honey.—1, Rev. F. G. Jenyns. 2 and 3, W. Sells. 4, R. Scott. 5, W. E. Warren. For the Best Exhibition of Comb Honey in Sections, each not more than 3 lbs. in weight, the total weight of each entry not to be less than 20 lbs.—1, J. Thorne. 2, S. Thorne. 3, T. W. Cowan. 4, W. E. Warren. 5, W. H. Dunman. For the Best 10 Sections of Comb Honey, each Section weighing not more than 3 lbs.—1, S. Thorne. 2, Miss Gayton. 3, P. Skinner. Extra, F. Cheshire. For the Largest and Best Exhibition of Run or Extracted Honey in Glasses, not to exceed 2 lbs. each.—1, R. Scott. 2, F. H. Lemare. 3, S. Thorne. 4, W. Sells. c, J. Walton.

ENGLISH COMB FOUNDATION.—For the Best Sample of Comb Foundation (worker cells) made of pure Bees' Wax, not less than 10 lbs. in weight, manufactured in the United Kingdom, with price per pound attached.—1, W. Raitt.

COTTAGERS' CLASSES.—For the Largest and Best Exhibition of Comb Honey, the property of one Exhibitor, and gathered by his own Bees.—1, P. Skinner. 2, M. Freeman. 3, T. Sells. For the Best Super of Honey.—1, P. Skinner. 1, H. Ellingham. 3, M. Wood. 4, T. Sells. For the Largest and Best Exhibition of Comb Honey in Sections, each Section not to exceed 3 lbs. in weight.—1, P. Skinner. 2, W. Martin. 3, W. Hunt. 4, T. Sells. For the Best Exhibition of Run or Extracted Honey in small glass jars not to exceed 2 lbs. each; total weight of each entry not to be less than 10 lbs.—1, J. Walton. 2, P. Skinner. 3, M. Wood. 4, T. Sells.

FOREIGN AND COLONIAL CLASSES.—For the Best Exhibition of Run or Extracted Honey in glass jars, not to exceed 2 lbs. each.—2, Lucio Paglia. For the Best Sample of Comb Foundation.—Bronze Medals, Newman & Sons.

COMESTIBLES.—For the Best Mead or Medheglin made from Honey, with Recipe attached.—1, Abbott Bros. 2, R. Scott.

MISCELLANEOUS.—For the Best and Largest Collection of Hives and Bee Furniture. 1, Neighbour & Son. For the Best Honey Extractor.—1, T. W. Cowan. 2, J. Walton. 3, Abbott Bros. For the Finest Sample of pure Bees' Wax, not less than 3 lbs. in weight, produced by the Exhibitor's own Bees.—1, W. Hunt. 2, W. Sells. 3, J. M. Hooker. 4, Lucio Paglia. For any Invention for advancing the Culture of Bees.—Silver Medal, F. Cheshire. c, Green & Sons; T. W. Cowan; F. Cheshire. For the Best Microscopic Slides illustrating the Natural History of the Honey Bee.—Silver Medal, John J. Hunter. For the Best and Largest Display of British Bee Flora in a dried state or otherwise.—Silver Medal, W. Ingram. Bronze Medal, A. E. Gibbs. For the Best Set of Diagrams illustrating the Honey Bee.—Bronze Medal, Abbott Bros.

DRIVING COMPETITION.—1, J. Walton (4 min. 15 sec.). 2, J. Fillec (4 min 15 sec.). 3, W. Hunt (8 min. 35 sec.)

OUR LETTER BOX.

Fowls Diseased (M. F. G.).—You had better treat them as directed by Mr. Moffat as follows:—The head may be bathed with warm water, or milk and water, and carefully dried afterwards; warm but airy lodgings must be provided, and boiled potatoes or oatmeal made into paste with milk given for food; and occasionally a clove of garlic beat up with a little of the oatmeal paste and made into pills may be put down their throats. Keep the fowls infected separated from those not infected.

Cork (R. M.).—If the Pheasants peck out pieces of it we do not think any injury will occur to the birds.

Much Swarming (C. D.).—You have not had an unusual number of swarms out of your four hives. In many cottage gardens may be seen as many as twelve or more stocks at the end of a season where only three hives had survived the winter. Of course such swarming is much to be deprecated, as it necessarily involves a proportionate failure in the honey harvest. If you had put your swarms in the place of the parent hives you would probably now have only eight stocks instead of nine. Less than one swarm out of each hive you could hardly have expected. Giving supers will not prevent swarming. Bees will even swarm before they have filled the parent hive—we had an instance in our apiary this season. Your high-growing Peas are too near your hives, but we do not think they have anything to do with their swarming. As to "burning" your bees with sulphur, it is a barbarous plan and utterly unprofitable. Drive the bees out of the hive to be plundered and join them at night to a neighbour's stock.

Grubs in Hive (M. A.).—The specimens of grubs thrown out were duly received. The hive is not foul-broody, but is turning out drones in all stages, from the termination of the larval condition to the time of gnawing out. The causes may be either singly or in combination, shortness of provisions, excess of drone comb, or an old queen. Feed gently and the difficulty will cease, but the cause should be sought and removed.

REMARKS.

18th.—Fine day with bright sunshine in forenoon, slight shower 3.30 P.M., fine evening.

19th.—Fine bright breezy day; slight shower 1 P.M., brilliant evening.

20th.—Very fine bright day throughout; clear moonlight night.

21st.—Very dull, hazy, close, morning; bright for a short time at noon, but generally overcast; thunder occasionally from 3 P.M., heavy shower at 6.30 P.M., moonlight night.

22nd.—Very thick, damp, morning; afternoon fine; fair evening.

23rd.—Very fine bright day throughout.

24th.—Morning dull and overcast with short slight shower, fine afterwards.

Rather fine week, with very equable and somewhat higher temperatures. The extreme difference between the daily maxima was only 5° (72.6° to 77.6°), and between the daily minima it was even less, being only 3.2° (54.0° to 57.2°).—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 28.

SOFT fruit being now nearly over our market presents a less busy appearance, and prices remain with little or no alteration.

CULTURE OF DISA GRANDIFLORA.

KNOWING that the desire to grow *Disa grandiflora* well is much more widely spread than the success which attends the efforts of growers generally, it may interest some of your many readers to learn the mode of culture which produced the specimen mentioned on page 71. Indeed, some of the most eminent public Orchid growers in England have told me that they can make nothing of *Disa grandiflora*. This is all the more to be regretted, inasmuch as its culture is extremely easy, and no Orchid so amply repays by distinguished beauty and long lasting the pains which may be expended on it. I may mention for the encouragement of others that the plant which I showed in Dublin on the 8th inst., and that bore the very unusually large number of twelve spikes of bloom, was but three years ago a very small piece taken off with the finger and thumb from the parent plant. I shall endeavour to be as explicit as possible, as nothing is more vexatious to anyone seeking directions than to find that important particulars are omitted.

Time of Potting.—I repot or divide the plants in autumn, after the flower spikes have withered, and when the young growth is actively pushing up.

Potting Material.—I employ sound, not sour or soddened, sandy peat, torn into rough lumps, not sifted or made fine, and merely the strong roots picked out. I add a liberal supply of rather coarse silver sand. I also add during the act of potting small pieces of charcoal about half an inch square in size.

Mode of Potting.—Whatever be the sized pot, I place in fully the quarter of it broken crocks and some charcoal, taking pains to place the drainage carefully; then lumps of peat and pieces of charcoal pushed in here and there between them and at the sides of the pot. I then lay in the plant, and place some of the finer parts of the peat about it. I throw in some sand as the work proceeds, and add more lumpy peat and charcoal. When all is finished I surface with sand, which the first good watering from a rose washes quite in.

Situation for the Plant.—This is, indeed, one of the most important matters in the cultivation of *Disa*, or, for the matter of that, of any plant requiring especial treatment. I grow mine in a large, airy, and very lightsome greenhouse, but not in any part of the greenhouse. I have a shelf over the door leading into a vinery, separated from the greenhouse by a glass partition. Here the plant has plenty of light, and yet not the full blaze of the sun. It has abundance of air circulating about it, even in winter when the lantern roof is opened,

except in frost, and yet it has no draught, which I know it much dislikes. Cultivators of *Disa* must avoid the notion that it likes heat and closeness. In its natural habitat on Table Mountain it has neither.

After-treatment.—This may be said to consist simply in supplying abundance of water. The plant should not once suffer from receiving insufficient water, and growers must recollect that *Disa* grows naturally in swamps which are often unapproachable. But, at the same time, I must warn your readers against the pernicious practice of standing the pots in saucers of water. When the plant is growing strongly it may be frequently syringed with advantage, as it tends to keep down green fly, with which growers are sometimes troubled. I am happy to say I am not. When the flower spikes are pushing well up I give an occasional supply of liquid manure very weak, made from sheep droppings. After flowering and before repotting, the supply of water may be a little diminished, but the soil should never be allowed to become dry.

In simple truthfulness I must now disclaim any credit for originality in the system of culture which I have adopted. I first saw *Disa grandiflora* in luxuriant health and beauty at Glasnevin Botanic Gardens. Mr. Pope, the able and kindly foreman of the houses, gave me in few words the outline of his treatment, and all the credit which attaches to me is that of having intelligently carried out his directions. But still there is something in that, as he tells me that almost everyone else to whom he acted the same kind part completely failed. I really see no reason why anyone who cares for the plant, and is willing to give it the trifling attention it requires, should not have their conservatories and greenhouses brilliant with *Disas*, as those at Glasnevin now are, where blooming plants are to be seen by the dozen.—FREDERICK TYMONS, *Clk., Dublin.*

SCALDED GRAPES.

LET me repeat that the so-called scalded berries are not scalded at all, but the very opposite—they are chilled. A correspondent once told me that a similar effect would be produced by placing ether on the hand and allowing it to evaporate. Of the effect of ether I have no practical knowledge, but supposing the statement to be correct, that is much in the same way that Grapes are injured when they are said to be scalded. A house need not become very hot to bring about the mischief; it might happen, I believe, at as low a temperature as 60° in this way: Supposing the night to have been cold so as to have lowered the temperature of the house to 50°, the sun is bright in the morning and the thermometer indicates 60° before any ventilation is given (this might happen as early as 5.30 or 6 A.M.); much moisture will have condensed on all the cold surfaces, such as metal, slate, stone, and unfortunately on Grapes, stems and leaves as well, where, unless a circulation of air is obtained, it will remain till the substance becomes warmed. No great harm has actually happened when the moisture is sufficient to be visible in the shape of dew, unless it might be a slight injury to the bloom on the skin of the Grapes, but it ought not to happen, and can easily be prevented.

The injury is done by the general instinct to dispose of the moisture as quickly as possible, which impels us to open the ventilators at once to a considerable extent, and suddenly cause a great amount of evaporation. Let it be distinctly understood that all the evil is traceable to this rapid evaporation, that

scalding is a misnomer and has nothing whatever to do with it, and I think intelligent amateurs will see their way more clearly to preventing it if young gardeners do not. Rust on the skin of the berries and the so-called scorched shoots are produced in exactly the same way. Why all these evils are more common than usual this year is first because there has been much cloudy weather since May, and the growth consequently is not so well consolidated as it is when produced under a reasonable amount of sunshine; and secondly because, when the sun has shone, it has generally had that peculiar scorching power so often experienced before thunderstorms, and has been accompanied by such excessive evaporations that many of the kitchen garden crops, Brassicas especially, drooped to the ground as if they were about to die, although they were more than sufficiently moist at the root. This rapid drying is a sure sign of coming wet, and generally too I think of thunder.

So-called scalding can always be prevented by timely ventilation—i.e., in anticipation of a rise of temperature. It can also be prevented by having fire heat and air all night, but that is both an expensive and a lazy plan, and should not be encouraged when the summer temperature is up to the average. For amateurs who attend to their own houses and find it inconvenient to be out as early as five or six o'clock I would recommend a slight shading, which could be pulled down late at night, and drawn up half an hour or so after the ventilators have been opened in the morning. Whenever I find air-giving has been too long delayed I do it very gradually indeed, and rather at the bottom than the top of the house at first. A temporary shading at such times would be a great advantage, especially during the stoning period when Grapes are much more liable to injury than at other times.—WM. TAYLOR.

THE POTATO DISEASE.

THIS is again to the front, and Scotch Champions, Magnum Bonums, &c., are this year found not to be so free from disease as previously, or these so-called "disease-proof" Potatoes have deteriorated in vigour and robustness of constitution, and are not now proof against the influences which cause the disease. This downward course appears to be nearly the same with all new varieties, and according to Mr. Mayne Reid (*vide Live Stock Journal*, March 5th, 1880) even applies to the Mexican "papas." Such being the case, the question that presents itself is, What is the cause of this deterioration of constitution? In answering this question I would first inquire into one or two analogous things. To retain the full vigour of a particular variety of Broad Bean or Pea, would you keep the inferior pods for seed or the best? Now what is done in planting Potatoes? In many instances the inferior both in size and quality, in many more the medium, in a few instances the best and largest tubers, are selected when dug and are used for seed. This last is the only way that the constitutional vigour of the Potato can be retained, as will be patent to anyone who knows something of Nature's laws of reproduction and will consider the subject for a moment. It is quite unnecessary to enter into the subject of spores, manures, thunder, rain, &c., as these have been exhausted; the majority who write on the Potato disease seeming to search for the cause anywhere before questioning the tuber itself.

I have tested the plan of keeping the largest and best Potatoes for seed, and at planting cutting into sets with two eyes each on three sorts that were very badly diseased two years ago. The result last year was that I only had good Potatoes from those planted in this way. This year the improvement continues in size, quality, and quantity. To put my opinion in a nutshell it is this: If we want hardy vigorous-constitutioned Potatoes we must be guided by Nature's law of selecting the fittest to produce from, which law is exemplified in all classes of the animal and vegetable kingdom.—W. B. W.

I DO not think there is anything mysterious about the disease attacking the Scotch Champions in the way referred to in last week's *Journal*. It is only what may be expected in the ordinary course of events. No Potatoes up to the present time, although some are properly called disease-resisting, are absolutely free from the attacks of the malady; nevertheless, I think that by care and attention to the raising of new seedlings some may eventually reach that stage of perfection.

The seed tubers last year were in a frightfully contaminated state nearly all over the country, and the statement that those planted by "G. R. B." were perfectly free from taint must be

received cautiously. It would require a very careful investigation and examination of witnesses to convince me that they were so. I feel sure the Editors are right in attributing the disease in the case referred to, to the old set. I would advise "G. R. B." not to be in too great a hurry to lift his crop of Champions. Let him proceed to the field with a fork and try half a dozen roots, and if the disease has only extended to the tubers in a comparatively few cases I should wait a few days for the chance of better weather, but if the case is really more serious than I anticipate there is no time to be lost. I have about three-quarters of an acre of Potatoes close to my residence, which I watch every day, and I have only met with three or four instances in which the disease could be attributed to the old set. Cases of that kind are not nearly as numerous as usual, thanks to the dry cold weather prevailing in the early part of the season. Since the heavy rains (about 7 inches), last month the leaves of the Potatoes have become spotted almost universally here, but the fungus does not progress on Magnum Bonum, Reading Abbey, &c., at anything like the rate it does on other varieties.

I have capital crops of original Ashleaf, Royal Ashleaf, and early Rose free from disease, and other people ought to have the same. About one-half of the losses by the disease arises from the want of knowledge and apathy on the part of the growers.—THE WRITER OF "THE POTATO DISEASE AND HOW TO PREVENT IT."

WE have this year an abundant crop of Potatoes—is it to be lost or saved? To-day I have finished lifting the second early Potatoes—i.e., Early Rose, Snowball, Snowflake, Brinkworth's Improved Snowflake, and Schoolmaster, all a heavy crop of magnificent tubers, quite sound and without a blemish, save some broken skins, which Dame Nature will soon set right. There are nearly forty sacks of them stored in open cribs as thinly as space would admit; and this impels me once more to urge everybody not to lose a day after the growth of the tubers ceases, but to lift and store them before disease attacks the haulm, which it will probably do with unusual promptitude and virulence owing to the frequency of heavy showers of rain. The rain on the 30th of July was so general and so heavy as to cause a sensible diminution of temperature on the following day. All the week we have had unsettled weather, and it was only by taking advantage of every interval of fine weather that the second stage of Potatolifting has been brought to so satisfactory a conclusion.

I may explain that the process of planting the Potato crop has for many years been divided into three distinct stages—the early varieties taken up some weeks ago; the intermediate or second early, just finished; and the late, to come in about a fortnight. "Lift as soon as growth ceases in the tubers," is the rule applied in turn to each section, and under tolerably favourable conditions of weather it is invariably applied successfully. The late varieties which I have under cultivation this year are Victoria, Dunbar Regent, Scotch Champion, Magnum Bonum, and Brinkworth's Challenge. All are looking well, the haulm being unusually strong and the tubers rather more than half grown. The showery weather which now prevails, while it brings disease into the intermediate sorts, is actually beneficial to these later varieties, tending to promote vigorous growth in tuber and haulm in the happiest manner, for experience shows that unchecked growth is of vital importance in the production of a full crop.—EDWARD LUCKHURST.

THE BEST ROSES.

THE "Journal des Roses" gives the result of a general appeal to the Rose-growing world of France for a list of the best Roses. The result is most interesting. To my mind they very greatly appreciate where our English electors have as yet failed to appreciate. While they (the French) profess to regard with tender feelings such varieties as Paul Neyron, Baronne Prevost, and Eugène Appert, we in England, whilst regarding these varieties with qualified satisfaction, consider Marie Baumann, Etienne Levet, Madame la Baronne de Rothschild, Marie Finger, François Michelon, Marie Rady, Sénateur Vaisse, Mons. E. Y. Teas, Souvenir d'Elise, &c., worthy of a place among the first fifty; but the French do not. Has the climate anything to do with the remarkable difference of opinion as existing between English and French Rose-growers? Out of our list of seventy-two best exhibition Roses the verdict of France pronounces for seventeen only as belonging to the class "the best Roses."

Let me now give some of the names high in merit in France. Baron A. de Rothschild (second only to La France), Jules Margottin (sixth), Charles Margottin, Souvenir de la Reine d'Angleterre, Madame Boll, Louise Odier, Elizabeth Vigneron, Géant des Batailles, Elize Boëlle, and Empereur de Maroc. Surely with regard

to only vigour and habit we must claim to be better judges than the French, for the habit of very many of the best of our exhibition Roses is nearly perfect.—J. A. W.

LIVERPOOL HORTICULTURAL ASSOCIATION'S SHOW.—JULY 31ST.

FAVOURER with a fine day after several weeks of rain, the second Show of this Association opened under pleasant auspices. The Show last year was an excellent one, but the Exhibition under notice was much superior. Specimen plants were of unusual merit, local exhibitors giving abundant evidence of their skill as cultivators. Fruit was plentiful and of great excellence, black Grapes being splendid; cut flowers very good, and vegetables admirable. Five very large marquees were quite filled round three sides of a square in the beautiful Sefton Park, the horticultural structures, &c., occupying the fourth side, the whole having a very imposing appearance. The tent devoted to specimen plants arranged on the ground down the centre, with Roses on the tables on one side and bouquets, &c., on the other, had a rich effect; such plants as *Ixoras*, *Allamandas*, *Bougainvilleas*, &c., with huge and highly coloured *Crotons*, appearing to great advantage amongst the grand Palms and fine Ferns. *Fuchsias* occupied gracefully the centre of the fruit tent. Tuberous *Begonias* were large and brilliantly laden with flowers, the finest display we have seen in competition. Zonal *Pelargoniums*, fresh and good, imparted brightness to the tent in which they were arranged; and *Coleuses* were 6 feet in diameter, close, and of excellent form and colour. The Exhibition was opened by the Mayor, who delivered an appropriate and interesting address, and a very large and select company attended during the afternoon.

STOVE AND GREENHOUSE PLANTS.—In the open class for twelve specimens, six foliage and six flowering, three admirable groups were arranged; the first prize being well won by Messrs. E. Cole & Sons, Withington, with, among others, grand plants of *Kentia Forsteriana*, *Latania borbonica*, *Croton Weismanni*, *Cycas revoluta*, *Ixora Prince of Orange*, and *Erica Lindleyana*. The second-prize group, staged by Messrs. J. Caldwell & Sons, Knutsford, included a well-coloured *Croton variegatus*, a large *Areca Bauerii*, and beautifully flowered plant of *Bougainvillea glabra*. Mr. J. Cypher, Cheltenham, was the only other exhibitor, and was adjudged the third prize. This group included a fine *Clerodendron Balfourianum*, well flowered plants of *Erica venosa*, and *Anthurium Schertzerianum*, a grand specimen of *Latania borbonica*, and a well-coloured *Croton majesticus*. Four exhibitors staged groups of six stove and greenhouse plants, the first prize being secured by F. R. Leyland, Esq. (F. Faulkner, gardener), with a very even lot, the most noticeable of which were the well-flowered specimens of *Vinca rosea* and *Allamanda Hendersonii*. Messrs. E. Cole & Sons secured the second prize. The best group of eight fine-foliaged plants was staged by Messrs. J. Caldwell & Sons, the second prize going to Mrs. Allison Johnson (R. Gibbon, gardener). The most noticeable plants in the premier group were *Zamia Lindleyi* and a large but rather weather-beaten *Cycas revoluta* in flower. Messrs. R. P. Kerr & Sons were the only exhibitors of six new *Crotons*, and were deservedly awarded the first prize for neat little specimens, *C. Prince of Wales*, *C. Baronne Rothschild*, *C. Bergmanni*, a large broad-leaved variety with beautiful creamy variegation; *Croton Evansianus*, and *C. Hawkerii*. The latter is a very distinct variety, of good habit, and broadly blotched with pale yellow. The same exhibitors also staged the only group of six *Dracenas*, and were awarded the first prize. Of these *D. anerleyensis* and *D. Mrs. Wills* were the best.

The premier prize group of eight table plants was exhibited by J. H. Oakes, Esq., Alfreton, Derbyshire. These consisted of rather too tall plants of *Croton Weismanni*, *Aralia filicifolia*, *Croton picturatum*, *Calyptronoma Schwartzii*, *Dracena marginata*, and *Pandanus Veitchii*. Plants worthy of notice in the other competing groups were *Acalypha musaica*, *Aralia Veitchii*, *Cocos Weddelliana*, and *Croton Johannis*. The best eight exotic Ferns were exhibited by R. Rayner, Esq., Wavertree, among which the most striking were the excellent specimens of *Davallia Mooreana*, *Gleichenia dichotoma*, *Cibotium regale*, and *Cyathea dealbata*. W. E. Bateson, Esq. (H. H. Elliott, gardener), also staged well in this class, and secured the second prize for, among others, good examples of *Davallia Mooreana*, *Adiantum farleyense*, and *Cibotium princeps*.

Orchids were not shown in great numbers, nor of any very marked superiority. The best six exhibited by M. Sparke, Esq., consisted of *Grammatophyllum Ellisii*, *Saccolabium Blumei*, *Russellianum*, *Cattleya Dowiana* (very richly coloured), *Oncidium Wentworthianum*, *Disa grandiflora*, and *Saccolabium Blumei majus*. The best four were staged by Mr. T. Faulkner, and included a fine pot of *Miltonia spectabilis*. Mr. James Cypher also exhibited successfully.

The first prize for six *Fuchsias* was awarded to T. Drysdale, Esq. (G. Butler, gardener), Worsley Hill, for tall well-flowered pyramidal specimens of *Mrs. Marshall*, *Alpha*, *Rose of Castille*, *Weeping Beauty*, *Vainqueur de Puebla*, and *Venus de Medici*. W. Bowring, Esq.

(J. Hurst, gardener), Aigburth, also staged well in this class, and obtained the second prize. This exhibitor staged the best six Zonal *Pelargoniums*, of which the most noticeable were the specimens of *Madame Vaucher*, *Triumph*, *M. de Lesseps*, and *Madame Van Houtte*. Several other exhibitors staged exceedingly well in this class.

In the classes open only to residents within ten miles of Liverpool, some of the freshest and best specimens of both flowering plants were staged, the progress made by several growers being very marked indeed. The premier prize group of eight stove and greenhouse flowering plants belonging to C. W. Newman, Esq., and exhibited by W. Mease, comprised large and remarkably well-coloured specimens of *Croton interruptus*, *C. angustifolius*, *Alocasia macrorrhiza variegata*, *Maranta Veitchii*, a grand plant of *Begonia Vesuvius* fully 4 feet high and as much through, and fine well-flowered specimens of *Ixora amabilis*, *Allamanda Hendersonii*, and *Dipladenia Barclayana*. The second-prize group, exhibited by R. Rayner, Esq., Wavertree, was but little inferior to the foregoing, and nothing could much surpass the beautiful specimens of *Croton angustifolius*, *Calamus ciliaris*, *Bougainvillea glabra*, *Gleichenia dichotoma*, and *Croton Disraelii*. Another excellent group, and which secured the third prize from F. W. Leyland, Esq., comprised a beautiful specimen of *Vinca alba* and a good *Gleichenia glaucescens*. H. Cosfield, Esq. (W. Blomley, gardener), and W. G. Bateson, Esq., also staged well in this class; beautifully flowered *Ixora coccinea* were included in each lot. The fine specimens of *Croton majesticus*, *Alocasia macrorrhiza variegata*, and *Alocasia Marshallii* were conspicuously good, and the premier prize group of six fine-foliaged plants, exhibited by R. Rayner, Esq. M. Sparke, Esq., likewise exhibited some good plants in this class. There was good competition in the classes for various single specimens, and the same may be said of the *Fuchsias*, *Pelargoniums*, and *Coleus*. R. Horsfall, Esq. (J. Stevenson, gardener) exhibited very fine specimens of the latter. The display of tuberous-rooted *Begonias* was unusually fine, notably the beautifully grown plants of *Emperor*, *Sedenii*, and *Kallista*, and a very fine seedling included in the premier prize group exhibited. E. Lawrence, Esq. (W. Wright, gardener), Aigburth. *Cockscombs* were well shown by L. Pilkington, Esq. (J. Moore, gardener), W. Mease, and others. The latter exhibitor also had the best pan of *Achimenes*. J. S. Cross, Esq. (S. Whitfield, gardener), secured the first prize for three Zonal *Pelargoniums* with remarkably grown and flowered specimens of *Lyon*, *John Gibbon*, and *Mary Pearson*; Mr. Wright being awarded the second prize for three but little inferior specimens. S. Cross, Esq., also secured the first prize for six varieties, staging in this instance good pyramidally-trained plants.

The silver cup offered for six stove and greenhouse plants was well won by that very successful exhibitor Mr. Mease with grand specimens similar in size and quality to those in the class for eight specimens.

ROSES.—The display was comparatively limited, the incessant rains for some weeks previous to the Show having done great injury to the expanding buds; yet some excellent stands were exhibited. In the principal open class for forty-eight triplets Messrs. Cranston added one more to their remarkable list of honours without any trouble, as they had no competitors. Some of their finest blooms were *La France*, *La Duchesse de Morny*, *Mrs. Jowitt*, a splendid Rose, having a general resemblance to *Marie Rady*, but brighter in colour and having much of the fragrance of the old Provins Cabbage Rose; *Etienne Levet*, *Annie Wood*, *Dr. Hooker*, very bright; *Mary Poehin*, very rich; and *Constantin Treiakoff*, splendid. The firm was in the same position in the class for thirty-six singles with fresh fine blooms, *Jean Sury* splendid; and *Abel Carrière*, *John Stuart Mill*, *Alfred Colomb*, and many others, very good. Messrs. James Dickson & Sons, Chester, followed rather closely with very full and fine blooms; they also staged still finer blooms in the class for eighteen Roses, *Comtesse d'Oxford* and *Souvenir de Victor Verdier*, grand; and *Mdlle. Annie Wood* and *Alfred Colomb* excellent, and secured the only prize (first) awarded. In the amateurs' class, T. B. Hall, Esq., Larchwood, Rock Ferry, secured the first position with twenty-four single blooms, small, but very fresh; T. Griffiths, Esq., Birkenhead, being second with generally larger flowers. We understood the points were equal for these stands, a casting point being awarded to the flower for general freshness. H. Thompson, Esq., Aigburth, (Mr. Savin, gardener), was third, but the blooms were pressed much too deeply in the moss. For two blooms, W. Just, Esq. (Mr. McMaster), Eastham, was an excellent first with excellent blooms admirably set up; T. Griffiths, Esq., being a good second, and T. B. Bull, Esq., third; an extra third being deservedly adjudged to C. P. Newman, Esq., Allerton (Mr. Mease, gardener). An extra prize was awarded to Messrs. Cranston & Co. for an extensive miscellaneous collection, and a first-class certificate was granted to them for the fine Rose *Mrs. Jowitt*, above described. Messrs. Dickson & Robinson, Old Millgate, Manchester, also exhibited standards of large full blooms, but much injured by the heavy rains.

CUT FLOWERS.—For a collection of twenty-four varieties Messrs. James Dickson & Sons were first with a splendid stand, in which *Dahlia Cervantesii*, *Coreopsis grandiflora*, *Centaurea Cyanus major*, and *Lilium puberulum* shone conspicuously. E. W. Newman, Esq. (Mr. Mease), was a very close second; and C. Harvey, Esq. (Mr. Bostock), an excellent third. For stands of twelve flowers F. R. Leyland, Esq. (Mr. Faulkner), was an easy first with fine trusses, and Mr. Bostock third.

For eighteen varieties of stove and greenhouse flowers Mr. Faulkner won the chief position with a splendid collection, including *Ixoras*, *Allamandas*, *Lapagerias*, *Hæmanthus Mannii*, *Orchids*, and *Kalosantheuses*, fresh and fine. Mr. Mease was a close second with a superior stand; and Henry Crossfield, Esq. (gardener, Mr. Blomily), an excellent third.

Bouquets.—In the open class for a bridal bouquet that skilful floral manipulator, Mr. James Cypher of Cheltenham, was in the premier position with a most tasteful arrangement of *Eucharises*, white *Lapagerias*, *Tuberoses*, and one or two white *Tea Rose* buds, from which rose in semi-drooping elegance small flowers of the old double white *Primula*; a few sprays of *Panicum variegatum* and *Maidenhair Fern* lightly used completed the arrangement. Messrs. Cranston & Co. were second with a smaller but very fresh and clean bouquet; Messrs. Jones, Princess Road, and Blomily being very close equal thirds. For two hand bouquets Mr. Cypher was again first, a few *Ixoras* and pink *Ericas* being associated with the white flowers; Mr. Blomily being a very close second; and Mr. Bodsworth, Stonehouse, Allerton, an excellent third. An extra prize was awarded to Messrs. Cranston & Co. for a rich and elegant arrangement of crimson, white, and yellow half-opened *Roses*. In the amateurs' class for a hand bouquet J. E. Reynolds, Esq., West Derby (gardener, Mr. Wilson), secured the premier position with a free and rich arrangement of *Cattleyas*, *Lælias*, *Miltonias*, and white *Lapagerias*; Mr. Bodsworth being second; Mr. Evans, gardener to Mrs. Lockett, Aigburth, and Mr. Hughes, gardener to R. J. Moran, Esq., Allerton, being equal thirds, all with highly creditable examples. The bouquets were numerous, and on the whole excellent.

GROUPS.—In the class for fifty miscellaneous plants arranged for effect Messrs. B. Kerr & Son secured the first prize with a splendid collection of choice and well-cultivated examples well arranged. Especially fine were *Anthurium Warroqueanum* and *A. crystallinum*, *Crotons*, and *Dracænas* were well coloured, healthy *Ferns* and *Palms*, and elegant *Humeas*. Messrs. F. & A. Dickson & Sons were second, and W. H. Walter, Esq. (Mr. Cox, gardener), third, but the groups were thin. It would be far better to stipulate space, and permit exhibitors to occupy it artistically with as many plants as they pleased, than to limit them to any given number.

Nurserymen's Miscellaneous Plants.—A large tent was devoted to these, and very beautiful was the effect that was produced. Messrs. F. & A. Dickson & Sons, Chester, exhibited a very large and fine group of *Conifers*, which included all the choice varieties of *Junipers*, *Cupressus*, *Retinosporas*, &c., in admirable condition; *Olearia Haasti* was highly effective in this group, which also contained stands of good *Roses*. Mr. Cowan, The Vineyard, Garston, exhibited *Vines* in pots grown from eyes this year, remarkable for their strong healthy appearance and firm short-jointed wood; some last year's *Vines* were bearing heavy crops of fine fruit, and attracted much attention for their excellence. Mr. Cowan had also a very large collection of well-grown decorative fine-foliaged plants of various sizes and in great variety. Messrs. W. G. Caldwell & Sons, Knutsford, occupied effectively a great length of table with small but very choice *Conifers* in variety, and an excellent assortment of table plants, very fresh and clean. Messrs. R. P. Kerr & Sons, Aigburth, arranged a collection of great merit and magnitude, foliage plants fresh and clean, and flowering plants bright. *Lilium speciosum corymbosum*, a permanently fasciated form, producing a fine corona of flowers, and M. Lemoine's new decorative show *Pelargonium* *Lucie Lemoine*, pure white, *Petunia*-shaped; and others were greatly admired in this group; and also were new *Zonals* by the same raiser, and the brilliantly coloured *Crotons*. The old *Humea elegans* was admirably cultivated, and *Gloire de Dijon* *Roses* worked this year on the seedling *Briar* were 10 feet high and altogether fine.

MISCELLANEOUS.—Conspicuous amongst the horticultural structures was an elaborate exhibition of wirework from Mr. J. Bramham, Liverpool. The "Rose Temple" was beautiful in design and execution, and would form an elegant adjunct to a flower garden or pleasure ground; stands, baskets, &c., were also included. Mr. Bramham also exhibited his boilers, showing them as set, which are much approved in the several gardens where they are in use. Mr. Halliday, Middleton, Manchester, had a very fine span-roofed house combining strength with lightness and efficient ventilation; he also exhibited useful garden frames of different forms and sizes. Mr. Webster, Wavertree, had a durable well built and excellently ventilated span-roof house with a lantern roof; also good frames. Mr. Beattie, Knotty Ash, had a small compact and strong greenhouse, well adapted for plant culture. Messrs. Foster & Pearson, Beeston, exhibited a superior span-roofed house, the same as the one that was so highly approved at South Kensington; also their silver medal frame with the "catch" ventilation, an advisable garden appliance both in the span-roofed and lean-to form; they had also their excellent throttle valves that are now largely used; and Mr. C. Kneale, ironmonger, had a large display of boilers of various types, and other appliances for the garden and household. A *Fern* case, exhibited by Mr. F. Roberts, gardener to W. D. Holt, Esq., attracted much attention. The *Ferns* have been preserved by a chemical process, and could scarcely be distinguished from growing specimens. An extra prize was awarded.

FRUIT.

The Fruit on the whole in the various classes was of unexceptionable quality, and better examples could not have been brought

together. The entries were numerous, and the show of fruit was very large, every prize being well contested. Seldom have Grapes been exhibited in better condition either as regards size of berry or finish generally. No better proof is needed of the quality and condition of the exhibits when such an excellent exhibitor as Mr. Coleman failed to gain a high position in the Grape classes, local growers securing the chief prizes. The Black Hamburgs shown by Mr. T. Washington, Rock Ferry, and Mr. J. Barker were wonderful examples, and the Muscat of Alexandria shown by Mr. Elsworthy and Mr. Mease were really magnificent. In the open class for eight dishes of fruit, not more than two varieties of Grapes, Earl Somers, Eastnor Castle (Mr. Coleman), was first with a fine collection including Muscat of Alexandria and Black Hamburg Grapes, Elrue Nectarines, good Queen Pine, Jefferson's Plum, Bellegarde Peaches, large and very fine in colour; Melon Victory of Bath, and good Brown Turkey Figs. J. H. Oakes, Esq., Alfreton (Mr. Jos. Ward), was a good second, and only a very few points behind the first-prize fruit with good examples of Madresfield Court and fair Muscat of Alexandria Grapes, Elrue and Pitmaston Nectarines, Jefferson Plum, good Brown Turkey Figs, and Melon Colston Basset, and a Queen Pine. R. E. Naylor, Esq., Hooton Hall, Cheshire (gardener, Mr. Hanagan) was third. In this collection Golden Champion was shown well without spot and large in the berry; Pitmaston Orange Nectarine and Royal Charlotte Peaches were large and good. In the class for two Pine Apples J. R. Leyland, Esq., Woolton Hall (Mr. Faulkner), was first with two good Queen Pines, weighing respectively 3 lbs. 11 ozs. and 3 lbs. 8 ozs. Second, Mr. Ward with good Queens. Another pair was also staged by Viscount Hill, Hawkstone (gardener, Mr. Pratt), which was of large size but rather under-ripe. For four bunches of Grapes, J. Just, Esq., Eastham, was first (gardener, Mr. S. McMaster) with superior well finished examples of Lady Downe's, Buckland Sweetwater, a beautiful colour; Foster's Seedling, and a large bunch of Alicante. R. C. Naylor, Esq., second with Golden Champion, Madresfield Court. Mrs. Pince, very good; and Foster's Seedling. For two bunches of Black Hamburg eleven collections were staged, and all the examples were highly meritorious. First, J. Johns, Esq., Rock Ferry (gardener, Mr. J. Washington), with the Frankenthal variety of Hamburg, very fine. Second A. Raynes, Esq., Rock Ferry (gardener, Mr. J. Barker). Third Mr. Coleman. J. G. Patterson, Esq. (gardener, Mr. T. Furguson), also staged fine bunches in this class. For two bunches of Muscat of Alexandria, A. R. Gladstone, Esq., Court Hey, Liverpool (gardener, Mr. J. Elsworthy), was first with good well-coloured bunches. J. Fielden, Esq., Tadcaster (gardener, Mr. H. J. Clayton), second with good bunches and berries not quite so well coloured. Third Mr. Jos. Ward. One dish of Peaches (six fruits), Mr. Coleman first with grand Bellegarde Peaches. Second, Mrs. Horsfall, Rugeley (gardener, Mr. G. Morral), with Barrington. Third, Mr. J. Miller, Sedgley Hall, Prestwich. The competition was keen, and ten collections were staged. One dish of Nectarines—first, Sir J. Earle, Liverpool (gardener, Mr. A. K. Keen), with well-coloured large fruits of Downton Nectarine. Second, Mr. Morral with Pine Apples. Third, Mr. Hanagan with Pitmaston Orange. Eight entries. For six dishes of hardy fruits the prizetakers were Messrs. Mease, Pratt, and H. Elliott, New Heys, in the order named.

In the corresponding local amateurs' classes, for collection of fruit, six dishes, Pines excluded, Mr. Furguson staged a very neat lot, and was awarded the first prize for Melon Munro's Little Heath, Vicomtesse Hericart de Thury Strawberry, Pitmaston Orange Nectarines, Bellegarde Peaches, and good Black Hamburg and Muscat of Alexandria Grapes. Mr. Elsworthy was a good second with the same varieties of Grapes and Peaches, Melon Dickson's Exquisite, May Duke Cherry, and Pine Apple Nectarine. Third, Mr. Hanagan, with good Madresfield Court and Muscat Grapes, Royal Charlotte Peaches, and British Queen Strawberry. Five collections were staged. For two bunches of black Grapes—first, R. Anderson, Esq., Tranmere (gardener, Mr. Metcalf), with Black Hamburg, fair-sized bunches, large in the berry, and well finished. The competition was very close, and ten lots were staged. Second, J. Barker with well-finished Madresfield Court. Third, Mr. Furguson with Black Hamburg, very large in the berry. For two bunches of white Grapes there were six entries; Mr. Mease secured the premier award with the best bunch of Muscats in the Show, the berries being exceptionally large. Second, Mr. Furguson; third, Mr. Elsworthy. For one Pine Apple.—First, Mr. Faulkner with a Queen 4 lbs. 4 ozs. Second, J. Reynolds, Esq., Sandsfield Park, West Derby (gardener, T. Wilson). Third, Mrs. A. Johnson (gardener, Mr. Lubbon). For one dish of Peaches there were nine exhibitors, Mrs. Lockett, Aigburth (gardener, W. Evans), first with *Violette Hâtive*. Second, W. D. Holt, Esq., West Derby (Mr. Roberts), with Bellegarde. Third, A. K. Keen with Royal George. For one dish of Nectarines.—First, Mr. Hanagan with Pitmaston Orange; second, W. Evans with Pine Apple; third, R. Horsfall, Esq., Aigburth (gardener, T. Stephenson), with Downton Nectarines. The silver cup for the special fruit prize for eight dishes of fruit was given by F. & S. Mee, Wood Street, Liverpool; there were four entries, and Mr. Mease again came to the front and was awarded the cup. Mr. Elsworthy and Mr. F. Faulkner also showed well in the first-prize collection. The bunch of Muscat of Alexandria was exceptionally large in the berry.

VEGETABLES.

These were numerous in quantity and shown in good condition

generally, especially the collection staged by Mr. Iggulden, Orsett Hall, Romford, which far exceeded any other for freshness and quality. Although local exhibitors came to the front in many plant and fruit classes, the vegetables grown in the neighbourhood did not reach that high quality those from the south possessed. In the open class for the best collection of twelve dishes, first R. B. Wingfield Baker, Esq. (gardener, Mr. W. Iggulden), with neat examples of White Globe Tripoli Onions, Egyptian-rooted Beet, Walcheren Cauliflower, Green Globe Artichoke, Sutton's Snowball Turnip, Monster Negro French Beans, a brace of a seedling Cucumber, Snowflake Potatoes, Culverwell's Telegraph Pea, Vegetable Marrow, and fine even Tomatoes of Hathaway's Excelsior, and Nantes Horn Carrots. The second award was obtained by Mr. J. Richardson, Boston, Lincolnshire, with a moderately good collection. Third, Lord Wimbourne, Canford Manor (Mr. Wm. Hinds), with very large Tripoli Onions and a splendid dish of Hind's Improved Tomatoes. The Cauliflowers in this collection were rather too large. Seven collections were staged. With four dishes of Peas Mr. J. Richardson, Boston, was first with Ne Plus Ultra, Commander-in-Chief, Imperial, and Dr. McLean. Mr. Iggulden was second with Culverwell's Telegraph, Carters' Telephone, Carters' Stratagem, and Carters' Challenger. Mr. Mease followed, eight collections being staged. In the class for six dishes of Potatoes Mr. Iggulden was first with fine examples of Porter's Excelsior, Beauty of Kent, Ashleaf Fluke, Extra Early Vermont, Snowflake, and Schoolmaster. Messrs. J. Richardson and Hanagan were second and third. In the local class for twelve dishes of vegetables Mr. Mease was placed first with fresh examples. Mr. Elliott; R. Horsfall, Esq., Grassendale Priory (Mr. C. Stephenson), taking the remaining prizes in the order named. In the class for a dish of Tomatoes good examples were staged by Mr. Mease, Mr. Faulkner, and Mr. Hall. Fifteen dishes were staged.

In this report no attempt has been made to refer to every prize-taker or even every class. The leading features of the display and the principal exhibits have been described, and an idea of the magnitude of the Show may be formed. It was unquestionably one of the finest of the year, and if the citizens of Liverpool give the support which the Society deserves still greater success will be achieved. The Show is wholly managed by gardeners, Mr. Richardson the curator of the Botanic Gardens being the able Chairman of the Committee, and Mr. Bardney Vice-Chairman.

A BEC PEACH.

FROM the general absence of the name of this variety in discussions on the Peach it is reasonable to suppose that A Bec is not widely known. The Rev. W. F. Radclyffe, Mr. Luckhurst, Mr. Wm. Taylor, and other writers have often spoken approvingly of several Peaches, and no doubt with good reason, but I do not remember their according a line to the one under notice. If they do not possess it I think they may well add it to their collections, while if they have it and yet do not consider it worthy of notice, it would be interesting to know the reason why. In my experience it is one of the finest Peaches in cultivation, the fruit being large, of good colour, and excellent quality. The tree is a good grower and bearer, at any rate under glass, not forced but merely sheltered; but of its adaptability for open walls I am not able to adduce any testimony. I observe that it has figured prominently this year on exhibition tables, and we are informed that Mr. Coleman exhibited it in grand condition at South Kensington. This confirms my testimony of the value of this Peach, which I think is worthy of more extended cultivation. As many cultivators may not be acquainted with A Bec, it may be useful to append the description from Dr. Hogg's "Fruit Manual":—"Fruit large, roundish, uneven in its outline, terminating at the apex in a bold blunt nipple, and marked with a shallow suture, which is higher on one side. Skin remarkably thin and tender, of a lemon-yellow colour, with crimson dots on the shaded side, but covered with a crimson cheek and darker dots of the same colour on the side exposed to the sun. Flesh white, with a very slight tinge of red next the stone, from which it separates very freely; remarkably tender and melting, sweet, and with somewhat of a Strawberry flavour. Flowers large. Leaves with round glands. This is a very fine and early Peach. It ripens in the third week of August. It originated at Ecully, near Lyons."

This description is very precise except that the nipple is not always bold; on some fruits it is very marked, but on others it is scarcely discernible. I have seen some very large fruits without this characteristic, while smaller examples on the same tree with a decidedly bluntly pointed apex. I esteem it one of the largest and finest of Peaches, and quite worthy of honourable mention in the columns of the Journal.—J. W. B.

SOWING ANEMONE SEED.—As a constant bloomer, quite hardy, and as a spring decorative flower, or for cutting purposes, there are very few to compare with Anemones in variety, especially *A. coronaria*. The present moist weather is an excellent time for sowing

seed. If anything is to be particularly guarded against it is sowing the seed on a raised dry bed, where the young seedlings run the risk of being scorched up. The fine fleshy filamentary rootlets are hopelessly ruined; at least they sustain a check that is not afterwards overcome by any amount of care. I prefer sowing in a rather deep box that can be afterwards fully exposed under the shade of a hedge or of trees, dividing the box or boxes into compartments for each variety. I gather my seed from selected plants, and never have failure in this way, and, as often mentioned in the Journal, I have splendid flowers.—W. J. M., *Clonmel*.

RIDGWAY'S GRASS CUTTER.

THIS is as good an implement for cutting grass as the hedge clipper is for trimming hedges, and that is saying a great deal. It is a marvellously handy tool, and will be most useful to persons

Fig. 25.

whose lawn is too small for them to hire a man to mow it, or to purchase a lawn mower for that purpose. It will also be very useful in large gardens for cutting grass verges and the scrollwork in geometric flower gardens, as well as for clearing those spots which the lawn mower cannot reach.

WESTERN HORTICULTURAL SOCIETY.

JULY 28TH, 29TH, 30TH.

THE summer Exhibition of this Society was a fairly good one; the schedule of prizes was most comprehensive, but the date fixed was not exactly suitable, as special inducements were offered for Dahlias, Gladioli, Asters, and Balsams, most of which were not well represented. Fruit and vegetables were well and numerous exhibited.

Plants.—In the class for twenty varieties of stove and greenhouse plants there was only one exhibitor—H. B. Mildmay, Esq., Flete, (gardener, Mr. Salway), to whom was awarded the first prize of £15 for a very creditable collection. Mr. Salway also exhibited the best group of plants on a stand 10 feet by 10. These collections or groups are always highly attractive at Plymouth. The Earl Mount Edgcombe (Mr. Brighton) took the second prize in this class, while Admiral Carme, Devonport, and Mr. P. Blunett were first and second respectively with smaller groups 7 feet by 7. Of six plants suitable for table decoration there were four collections, all of which were remarkably clean and even. Mr. Salway, sen., was placed first: E. C. Baring, Esq., Membrand Hall (Mr. Salway, jun.), second; and the Earl of Devon third. Several admirable collections of Cockscombs and Balsams were staged, the first-named being particularly fine. Zonal Pelargoniums and Petunias were also numerous.

Ferns were splendidly exhibited, the premier collection of twelve varieties was remarkably fresh. These were from the gardens of S. Hurrell, Esq., Kingsbridge Road. Mr. Salway was a very good second, and the Earl Mount Edgcombe third. Messrs. Lucombe, Pince, & Co. exhibited two very fine collections of stove and greenhouse plants, which indicated the vast wealth of their nurseries at Exeter.

Cut Flowers.—Notwithstanding the early date for Dahlias there

were several very good collections set up by Messrs. Kemp, Radmore, Whitmore, and Bluctt, who were the principal prizetakers in the classes for twenty-four, eighteen, and twelve. Roses were fairly represented. Messrs. Curtis, Sanford & Co., Torquay, were first in the class for forty-eight distinct and also in the class for twelve; Miss Christy, Coombe Bank, Kingston-on-Thames (Mr. Moorman), was second, and Mr. Mitchell third.

Fruit was numerously represented. The Earl of Devon exhibited the best Grapes, well coloured and finished. Peaches from the gardens of the Earls St. Germans and Mount Edgcombe. A very fine Queen Pine was exhibited by Mr. Allen, Ivybridge, who was worthily awarded the first prize, the Earl of Devon the second. The bush fruit exhibited was numerous and fine.

Vegetables.—These occupied a table the whole of the length of the hall, and in many of the classes there were twenty competitors. Potatoes large, bright, and clean; Carrots and Turnips were similar.

The Exhibition this year was held in the new Guildhall, Plymouth, a most suitable place for such a display. The Show was well managed, and we congratulate the executive on their success.

WHITE EAST LOTHIAN STOCKS AND DOUBLE TUBEROSES.

WHAT magnificent plants the white East Lothian Stocks are in early summer for various purposes—the adornment of the garden, for cutting, for bouquets, &c. I send you a plant which is no more than an average one from an early batch of this year's seed-sowing. I could, had I not cut some of them, found a much better sample. The flowering shoots were much broken by the heavy rains recently. I think they are not sufficiently appreciated—that is, their beauty and usefulness when well grown does not seem to be considered, or we should see them more generally cultivated.

Amongst choice white flowers perhaps there is not a more general favourite than the double Tuberose. Certainly the plant itself is not especially attractive, but those who have to maintain a supply of choice flowers will find the pure white exquisitely fragrant blooms of great value. I had yesterday a scape bearing no less than a dozen fine flowers. I have not had great experience in Tuberose culture, but I do not recollect having one with a dozen flowers open at one time before.—R. M. A.

[The plant of East Lothian Stock we received was a very fine specimen, bearing nearly twenty dense racemes of fragrant white double flowers. The double Tuberose was also exceptionally beautiful, the individual flowers being of good form, and the fragrance most pleasing and powerful.—EDS.]

LEEDS HORTICULTURAL SOCIETY. SUPPLEMENTARY SHOW.

IN consequence of the loss arising from the fine Show in June owing to a deluge of rain the Committee, having collected £200, resolved on another venture in the hope of reimbursing their finances; hence they attempted another Show with other attractions for ensuring a large attendance of visitors. The Show was comparatively small, many who had entered failing to fulfil their engagements. The weather was fine until the afternoon, when drenching showers fell, and it is somewhat doubtful if the object of the industrious Committee will be attained.

The bouquets were the finest feature of the Show. The special prize of two guineas offered by Mr. Boston, fruiterer, Boar Lane, Leeds, for the best ball bouquet was won by Mr. Featherston, St. Ann's Nursery, Leeds, for a highly finished arrangement free and chaste of *Panratiums*, *Bouvardias*, white *Lapagerias*, Tea Rose buds, *Tuberoses*, and a spray of Orange blossom and a few nodding flowers of *Rhodanthes*; Mr. Wright's bouquet being highly commended. A similar prize for the ball bouquet was won by Mr. Wright, gardener to Grosvenor Talbot, Esq., Southfield, Burley, Leeds, for one of the most beautiful bouquets we have ever seen exhibited, brightness, freshness, and freedom being combined in a very marked manner. The flowers employed were *Panratiums*, *Lælias*, *Miltonias*, red *Bouvardias*, *Stephanotis*, and a spray or two of *Oncidiums*. The Society's prizes for ball bouquets were won by Mr. Frankland, gardener to J. Barran, Esq., M.P., Chapel Allerton Hall, Mr. C. Rylance, Ormskirk, and Mr. Wright in the order named. Splendid white *Lapagerias* predominated in the first-prize arrangement, with *Tuberoses*, *Panratiums*, and *Stephanotis*. It was rather small, but very clean and free. In the corresponding class for ball bouquets Mr. Wright, Mr. Featherstone, and Mr. Rylance secured the prizes in the order named in a very close and excellent competition.

There was a moderate display of fruit. Mr. Clayton, Grimston Park, was placed first with a grand collection of fruit—two varieties of Grapes, Peaches, Nectarines, a Pine, and Little Heath Melon, weighing 9 lbs.; Mr. Clark, Studley Royal, following, Golden Champion Grapes being very fine. Mr. Clark was first in the class for four dishes. For two dishes of Grapes the prizes went to J. Padgett, Esq., Guiseley (Mr. Thompson, gardener); Geo. Gelder, Esq., Headingley (Mr. Tuke). J. Hardy, Esq., Grantham (gardener, Mr.

Goddard), was first with black Grapes, with admirable examples of Black Hamburg; and the first prize for white Grapes was won by Mr. J. Stevenson, The Gardens, Farfield House, Armley, with large bunches of Foster's Seedling. Mr. Clayton was first with a Pine, Mr. Clark with Peaches (good), and Mr. Goddard with Nectarines. Several good dishes of small fruit were staged. Mr. E. P. Dixon, Hull, sent a very fine dish of a seedling Raspberry, which was highly commended for its size and high quality.

Plants call for little notice. In the 200 feet group Mr. Featherstone was an excellent first with a free and bright collection; J. Barran, Esq. (Mr. Frankland), a good second; and Mr. Simpson, New Lane, Selby, third. The smaller groups do not demand notice. Mr. Barran staged the best fine-foliaged plants and Ferns; Mr. Gelder the best flowering specimen; W. H. Gott, Esq., Armley House, Leeds (Mr. Meredith), the best Orchids, *Cattleya crispa superba* being good.

Messrs. Mack & Son, Catterick Bridge, were the principal exhibitors of Roses, staging very fine blooms; Mr. Samuel Hartley, Headingley Nurseries, closely following. Mr. Rylance had the best tender, and Mr. Hartley the best hardy cut flowers, both staging fine boxes. Mrs. Cowl, Burton Lane, York, had the best Carnations and Picotees; and Mr. Rylance and Mr. Henry Clark, Rodley, Leeds, the best Dahlias, the blooms being of excellent quality.

FRUIT-GROWING IN INDIA.

I HAVE to thank you for the book which you so considerably sent to save me time. It is a clear well-arranged manual, of which I am sure to be able to make some use. I have gone cursorily over it, and do not see any great difficulty in being able to follow its directions; but evidently the author makes it a condition *sine quâ non* of success that his dwarfs, pyramids, &c., must have complete rest for five or six months of the year. Now, our weather is so nearly uniform that I find it hard to determine without experimenting for some years which six out of the twelve months would be best suited to give rest to the trees. The time when they are at rest with you is the time here which most nearly approaches all the conditions for favouring growth, blossoming, and fruiting. Of the remaining period of the year four months (from June to September) are constantly wet, leaving only October for rest, November being the month for starting, as March is with you. If I want to rest the trees at all I must do it in the four wet months, and of course that can only be done under glass.

Any number of a few varieties of Peaches, Nectarines, and Apples can be had here from the hills, but they will be all seedlings, no grafted or budded plants being procurable. Of course my plan must be to have some "maiden trees" on approved stocks of some of the most desirable varieties that you will kindly recommend. I will also get out pips and stones for raising seedlings of the Quince and Paradise to serve as stocks for Apricots, Peaches, and Apples.

Now, I shall thank you for advice—1, As to the necessity and time for giving rest; 2, Whether "maiden trees" can arrive here safely when packed in a state of rest; and 3, The proper people to go to for my purchases.

Coming to another subject, I am glad to confirm all that Mr. F. Cheshire has said in the Journal as to the experiment of transporting bees to India, as I am the foreign correspondent referred to therein. I am very sorry my experiment failed, as we have here all the elements of success required for breeding bees. I have not yet tried the experiment promised in the concluding portion of the extracts given by Mr. Cheshire.—A PARSEE.

[1, The trees must have rest, but not necessarily for five or six months. After the fruit has been gathered, or towards what is your autumn, gradually withhold water from the trees in pots, and when the rainy season commences lay the pots on their sides, so that the soil is kept moderately dry. As to the duration of rest we can only say, Afford the trees all that your climate permits. 2, Fruit trees are successfully sent from England and America to all parts of the civilised world. 3, We think you will do best by obtaining trees from America, requesting some good nurserymen there to send you those varieties that succeed best in the southern States. You might write to Messrs. P. J. Berckmans & Co., Augusta, Georgia; or if there is not direct communication from there to Bombay, a good firm for you to apply to is Messrs. Ellwanger & Barry, Rochester, New York. We shall be glad to hear the result of your experiments, and wish you much success both in fruit culture and bee management.—EDS.]

VIOLETS IN JUNE AND JULY.—During June I gathered several flowers of Violet *Argentæflora*, and to-day (July 26th) I gathered enough blooms to make a bunch 6 inches in diameter from three dozen small plants. What I have long been desiring appears to have been obtained at last—viz., a variety that would supply sweet-scented Violets all the year round. *Argentæflora* appears to be a

continual bloomer, producing flowers from every joint of the stems, and the young runners throw flowers directly crowns are formed. It is a very sweet Violet, and has capital footstalks, admitting of the flowers being made up into large bouquets.—G. ABBEY.

EVESHAM FLOWER SHOW.

THIS Show was very successful and extremely well managed, and the following brief notes upon it may be of interest. First on the schedule were cut flowers, and of these Roses were the chief feature. In the open nurserymen's classes for thirty-six, distinct, single trusses, Messrs. Cranston were a long way first, their Général Jacqueminot reminding one very forcibly of the splendid treble shown by this firm at the Crystal Palace. Has the Herefordshire marl anything to do with the colour possessed by Messrs. Cranston's Jacqueminots this year? Mr. Corp of Oxford was a good second; Messrs. Cranston were also easily first with twenty-fours and twelves, and for the best collection of Teas. The same firm was followed by Mr. J. Mattock, Oxford.

In the amateurs' classes Mr. T. Jowitt, Hereford, was first with twenty-fours, distinct, single trusses, with splendid blooms of Alfred Colomb, Ferdinand de Lesseps, Emilie Hausburg, superb; J. S. Mill, Marie Finger, and Duke of Wellington, very good. Rev. J. A. Williams of Yardley Wood near Birmingham was second with good blooms of Marie Rady, Charles Crapelet, Marie Van Houtte, Anna Ollivier, and Marie Baumann, the latter perhaps the best bloom in the Show. Mr. A. Evans, Oxford, followed with smaller and rather soiled flowers. In the local classes for twelve distinct varieties Mr. Julins Sladden, whose collection of old Roses at the Crystal Palace two years ago won so much interest, was first with an excellent and even collection. Many very creditable blooms were staged in these local classes.

With regard to the other divisions of the Show, I must not forget to mention Mr. James Betteridge's (of Chipping Norton) collection of herbaceous plants. His double Pyrethrums and Delphiniums, &c., were excellent. This stand was in my opinion one of the features of the Show. The bouquets were good, and we were glad to see that Mrs. Evans, the wife of the indefatigable Secretary, was so successful in this class. The well-known Ettington Park Gardens contributed well in the classes for fruit.

In spite of heavy and frequent thunderstorms visitors patronised the Show right royally. Mr. Rowe, nurseryman, Worcester, gave extra prizes in the amateurs' classes.—J. A. W.

THE CELERY FLY.

LAST year this pest was very abundant, and severely injured the Celery crops in this neighbourhood. I also hear that many of the plantations in the market gardens round London were almost ruined by the same destructive enemy. Soon after our plants were placed in the trenches this year I observed the blistered leaves containing the grubs. Slugs were also numerous and attacking the plants. We strewed a mixture of lime and soot over the plants, hoping to arrest the progress of both intruders; it had the desired effect on the slugs but not on the grubs. After this at the commencement of rain I gave a slight sprinkling of nitre on the beds, and repeated the application in a fortnight on the approach of a shower. This with a plentiful supply of water at the roots is causing the plants to make rapid growth. The blister is still observable, and the grubs can still be found, but only on the lower leaves. By timely attention in removing as many of these leaves as can be spared, pinching with the thumb and finger the affected parts of those that cannot be removed, giving liquid manure freely, and an occasional sprinkling with nitre in showery weather, I think we shall reduce the ravages of this pest to a minimum.

Doubtless the cause of the fly becoming so abundant last year was owing to the coldness of the season, which caused the plants to grow slowly, so that they had no power to resist their enemy.—ROBT. D. LONG, *Thorne House, Wakefield.*

LIKE many of your correspondents my Celery plants have been severely affected by this fly. I planted two rows of the variety Sandringham White on the 20th of May, and in two or three weeks I saw signs of the attack of this insect. It appears to deposit its eggs on the under side of the leaf, generally near the edge, though occasionally I have found them near the base of the lobes. How long it is from the time the eggs are deposited on the leaves until the grub is developed I am not certain, but of this I am painfully aware, that when the grub does commence it is capable of consuming the pulp or parenchyma of an entire lobe of the leaf in from four to six days. Here the fly attacks the white more than the red varieties, though whether that is because the white was planted before the red I am not prepared to say. It completely spoiled the whole of my Celery last year, both white and red. The Celery at present appears much better than at this time last year, which I attribute to my greater diligence in looking

after the insect. I think it would be useful to know the position of gardens where the attack is very severe, as I have come to the conclusion that insect life generally is more prevalent in so-called sheltered gardens than in those that are open.

I do not find the application of lime act as a check to the fly. It is of no use to destroy the grub when it is once on the leaf. I have not tried soot, but the lime I have used is fresh-slaked grey lime. The only good I can see in the application of lime is that it compels the grubs to leave the Celery for a short time, but after the lime has been exposed to the atmosphere for a few hours it has lost its power, and the grubs return, and to apply it with any amount of success it would have to be done several times a day. I see it is recommended to crush the grub between the thumb and finger, but I find that it is not always so effective as would at first appear, as it happens if the attack is very severe that, beside the larger insects, there are sometimes two or three of smaller size, and in only crushing the large one and leaving it on the leaf the others escape. The only effectual way I have found is removing every part that is blistered. I can understand where there is only a slight attack that applying lime may be efficacious. My method is to diligently examine the Celery very often—every day if possible, and remove every blistered portion of the leaf that can be seen, but I never take more than is necessary, as the loss of every piece of leaf tends to weaken the plants.—W. H.

GLOUCESTERSHIRE SHOW.

LAST week the Gloucestershire Agricultural Society held their annual Show in The Park, Gloucester, and at the same time a remarkably fine horticultural exhibition took place. The Hon. Sec. was Mr. J. C. Wheeler of the Gloucester nursery and seed firm, and the management was in the hands of the officials of that establishment, who gave great satisfaction to the exhibitors by their admirable arrangements. Two spacious tents were devoted to the exhibits in this department, both being well and effectively filled—one with plants, cut Roses, &c., the other with fruit and vegetables.

In the open class for twelve plants in or out of bloom Mr. James Cypher, Cheltenham, was an easy first with handsome specimens. Second, Mr. J. T. Agg Gardner; third, Mr. Barnes. Fuchsias were small, but the specimens were clean and healthy; Mr. W. Nicks, Longford, and Mr. Barnes being the chief prizetakers. Zonal Pelargoniums were well shown by Messrs. Wheeler & Son and Mr. Barnes. In the smaller classes for ornamental stove and greenhouse plants the prizes were mostly divided between Mr. Cypher, Messrs. Wheeler, and Mr. Barnes. Exotic Ferns were admirable, T. Gambier Perry, Esq. (gardener, Mr. John Sowray), Highnam Court, Gloucester, being first with fine specimens of *Adiantum farleyense*, *A. tenerum*, *A. gracillimum*, and *Davallia Mooreana*. Gloxinias were small but good, Mr. W. Fletcher being first, Mr. Cypher second, and Dr. Campbell, Gloucester, third. One variety (Queen Victoria) amongst these was very attractive.

A fine feature in the Exhibition were the baskets of plants arranged for effect. Some of these were large hampers 5 or 6 feet in diameter, filled with Palms, Dracenas, Caladiums, Ferns, Crotons, Begonias, Selaginellas, &c. The first-prize hamper came from Mr. Cypher, second from Mr. Tolley, and the third from Messrs. Wheeler. Roses were shown in fine condition. For twenty-four cut blooms, distinct, Messrs. J. Jefferies & Sons, Cirencester, were first; but the second-prize collection from Mr. W. J. Grant, Hopend, Ledbury, were superior in many respects, many of the blooms being larger and fuller. Mr. W. Smith, nurseryman, Kingswood Hill, Bristol, was third with neat blooms.

Fruit was well represented. For a collection of eight dishes Mr. Coleman, The Gardens, Eastnor Castle, was first with fruit of great merit; second, Mr. Sowray, and third Mr. C. Tolley, the latter two falling off very much in Grapes. For three bunches of black Grapes Mr. Coleman was again first with magnificent bunches; Mr. Sowray was second with well-coloured bunches, but smaller than Mr. Coleman's. In the class for three bunches of white Grapes Mr. Coleman was again first with Muscat of Alexandria in the same fine condition as the Hamburgs; second, Mr. J. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, South Wales, with bunches smaller than Mr. Coleman's, but better in flavour than some other varieties shown in the same class. For the Pine Apple, any variety, Mr. Muir was first with a finely grown Queen, Mr. Coleman being second with a good fruit of the same variety but slightly over-ripe. Peaches were good. First, Mr. Coleman; second, Mr. Sowray. Nectarines very high in colour and fine. First, Mr. Coleman; second, Mr. Muir. Figs.—First, Mr. Shingles, The Gardens, Tortworth Court. Cherries.—First, Mr. Coleman with a dish of Black Circassian extremely fine. Strawberries were good. Melons rather poor in appearance but rich in flavour. Scarlet-flesh, first Mr. Coleman with Read's variety. In green-fleshed sorts G. Moffat, Esq., Goodrich Court, Hereford (Mr. Spencer), was first with a fruit of William Tillery. Gooseberries, Raspberries, and Currants were shown in large quantities and fine condition.

Vegetables were satisfactory both in quantity and quality. For the collection of nine varieties there were ten entries, the first prize being secured by Mr. J. Muir with a superior collection; second,

Mr. J. Turk, Cheltenham, who had also a fine collection—as, indeed, had all those competing. Messrs. Wheeler offered liberal prizes for vegetables of their own introduction, such as the Gloucestershire Kidney Potato, Empress of India Cucumber, Kingsholm and Tom Thumb Lettuces, Beetroot, Peas, &c., and the numerous collections staged were creditable in the highest degree.

On the centre of the fruit table the bouquets and vases of cut flowers were appropriately arranged, and for these Miss Cypher of Cheltenham outdistanced all others, her arrangements being extremely light and elegant. Amongst various extra exhibits Messrs. Wheeler showed a fine stand of cut Roses and various well-grown plants, and in the agricultural department the same firm had a large collection of agricultural seeds, and Grasses testified to their undeniable quality.

ON Monday last an ARTISAN'S SHOW was held in the Gardens of the Royal Horticultural Society, South Kensington. The exhibits were not very numerous but of generally good quality. Capt. Patton's large group of plants also remained on view, and in addition the Exhibition of the British Bee-keepers' Association was opened to the visitors. The nominal fee of 2d. was charged for admission, and above 11,000 persons assembled during the afternoon notwithstanding the frequent showers.

— TWO cases of what is perhaps the most destructive and difficult to eradicate of all garden pests have come under our notice during the past week—viz., the PHYLLOXERA ON VINES. Those whose Vines, young Vines especially, which are apparently in an unhealthy condition (while they are at the same time in suitable soil, and receiving otherwise good treatment), should, if they are in doubt on the subject, send us a sample of the foliage of the young laterals, and also of the fibrous roots, for examination, as it would be a great calamity if this terrible pest were permitted to spread in this country.

— SWEET and chaste white flowers for bouquets and vases are always welcome from the beginning of November onwards, and hence the popularity and usefulness of ROMAN HYACINTHS. For having these early no delay should occur in potting the bulbs, five or six of which should be placed in a 5-inch pot, the soil employed being rich, light, and sandy. The pots should then be plunged in ashes, and when filled with roots and the growth appears above the soil the pots may be placed on a shelf in a moderately heated house. Successional batches of bulbs may be potted at fortnightly intervals, those for early flowering being put in at once.

— A CORRESPONDENT, "J. E. B.," writes to us approvingly of CONQUEROR OF EUROPE MELON for growing in frames with a few leaves for affording a gentle bottom heat for starting the plants, and no top heat in addition to that of the sun. "This Melon," he says, "is one of the hardiest of all, one of the freest croppers and best setters, while the fruit is handsome and of excellent quality." The true variety—and it is not always possessed by seedsmen—is rather oval-shaped with a bright yellow skin and finely netted, the flesh being nearly white."

— WE have recently seen a fine batch of ELLAM'S EARLY CABBAGE, and it may be useful to mention the fact at this the period of sowing the seed, for the spring crop of this most important vegetable. The crop to which we refer was raised from seed sown in the spring; the plants are very dwarf, the firm medium-sized hearts almost resting on the ground. This new variety is well worthy of trial, and may probably with advantage be included in the three or four varieties that are grown in many gardens.

— AN excellent gardener speaking to us on preventing the

attacks of the CELERY FLY, suggests the application of paraffin in very small quantities. He has been syringing his rows lightly once or twice a week with a water in which a small wineglassful of paraffin has been mixed in every four gallons, and the plants have greatly improved in appearance. He suggests that probably if rags were dipped in paraffin occasionally and suspended near the rows that the fly would not alight on the plants to deposit eggs. The proposed plan is worthy of being tried, as the second attack of the fly usually occurs in August.

— THE northern division of the NATIONAL CARNATION AND PICOTEE SOCIETY will hold the annual Exhibition on Saturday, August the 14th, in the Botanical Gardens, Manchester. The Botanical Council grant £10 towards the prize fund, exhibition space, and free passes to exhibitors. All inquiries should be addressed to the Honorary Secretary and Treasurer, the Rev. F. D. Horner, Kirkby Malzeard, Ripon.

— DURING the past week there have been two EXHIBITIONS OF PLANTS AND FLOWERS at the Crystal Palace. On Saturday Messrs. Cranston & Co., Hereford, sent about 12,000 Rose blooms, which were arranged on a low sloping central stage. A large number of varieties were represented, many of the blooms being exceptionally fine. On Monday Messrs. Laing & Co., Forest Hill, J. Peck & Son, and the General Horticultural Company, exhibited large groups of plants, comprising handsome specimen fine-foliage plants and others very pleasingly arranged.

— IN one of the carpet beds at Battersea Park a NEW VARIETY OF ALTERNANTHERA is very noticeable for its distinct and bright appearance. It is a form of *A. paronychioides* with larger leaves of a bright yellow tinge that is very effective. It is appropriately named *A. paronychioides aurca*, and as arranged in contrast with the brightly coloured *A. amoena* is most pleasing. The carpet bedding in this Park is now in its best condition, the colours being bright and the designs tasteful.

— AS a means of preventing the attacks of insects and mildew on Roses and fruit trees what may be termed BARDNEY'S INSECTICIDE deserves special mention on account of its simplicity and efficiency. The Tea Roses that are growing so luxuriantly in the excellent house devoted to them in Mrs. Heywood's garden at Norris Green, and the remarkable cleanliness and rich colour of the foliage of the Peach trees in the several houses, afford striking testimony of the value of this insecticide as used by Mr. Bardney. About 2 lbs. of soft soap are placed in a saucepan with a little water, and boiled for about twenty minutes. This is mixed with five or six gallons of water and kept in a large flower pot. Half a pint of the solution is placed in a large waterpot full of water used for syringing. Neither insects nor mildew appear able to exist on the foliage, while nothing can exceed the admirable condition of the trees and Roses. It is important that it be used regularly, that is whenever the syringe is employed.

— IN the same garden some VINES IN POTS afford evidence of very superior culture. A cane of Duchess of Buccleuch is bearing five bunches as fine as are usually seen on established Vines. Foster's Seedling and the Black Alicante are also remarkably fine, bearing bunches and large and well-finished berries. The Vines are one-year canes, grown by Mr. Cowan at the Garston Vineyard in 10-inch pots, and just when commencing growth they were shifted into 13-inch pots, and to this additional root room Mr. Bardney attributes much of his success in producing such excellent Grapes.

— WE are informed that Mr. Bentley of Scarborough has invented an APPLIANCE FOR SYRINGING PLANTS, which is noteworthy for the fact that it may be charged in separate compartments with pure water and a liquid insecticide, either of which may be ejected at the pleasure of the operator.

— A CORRESPONDENT writing from Brockham in Surrey upon THE RAINFALL during the past week, states that between 9 A.M. on July the 29th and 9 A.M. July the 30th 1·7 inch of rain was registered, or above 1½ inch in twenty-four hours.

— IN the suburbs of Reading there are many picturesque residences, which in several instances are situated in very ornamental and well-kept grounds. One of the best places in this respect is that owned by Mr. Martin Sutton, senr. This gentleman, although still one of the senior partners of the well-known firm of seedsmen, the Messrs. Sutton & Sons, really takes no active part in the business, but being in good health naturally takes a keen interest in what is going on, notably in the nursery and trial grounds, and horticultural pursuits generally. He has every reason to rest contented with his past labours and achievements, and also with what is still being done by the junior members of the families of the Brothers Sutton.

— WE are informed that the ALEXANDRA PALACE FRUIT SNOW will be held on the 3rd, 4th, 5th, and 6th of September, when liberal prizes will be offered for collections of fruit.

— WE have received from Mr. E. P. Dixon, Queen Street, Hull, fruits of a NEW RASPBERRY which are very large, of good form, and fine flavour. Mr. Dixon states, "It originated from the Northumberland Fillbasket, but is ten days earlier, of more robust growth, frequently bearing fruit in the autumn from the same season's canes, and the fruits are larger, of deeper colour and better quality than its parent."

— WE learn that the autumn Exhibition of the READING HORTICULTURAL SOCIETY will be held August 19th in its usual picturesque position—namely, the Abbey Ruins, Forbury. In addition to the large number of classes provided in the schedule Messrs. Sutton & Sons will offer a silver cup, value £5 5s., for a collection of fruits, comprising eight dishes of distinct kinds.

— NOT only are ORCHARDS in many parts of the country almost destitute of fruit, but many of the Apple trees appear to have received considerable injury by the wet autumns and severe winters of the past few years. In the case of hundreds of trees that we have seen both in the northern and southern counties nearly all the growth made last year appears to be killed, and the trees present a most unsatisfactory appearance, while the foliage has a sickly hue, the fruit is small, and a large proportion is dropping off.

— WE learn that the WEST OF SCOTLAND PANSY SOCIETY'S EXHIBITION held on the 28th ult. in the City Hall, Glasgow, proved very successful notwithstanding the unfavourable weather that prevailed. There were upwards of four hundred entries, about two hundred varieties of Pansies being represented in very fine condition generally. Roses and Pinks were also exhibited, and miscellaneous collections of plants were provided by Messrs. R. Bullen, Botanic Gardens, Glasgow; G. Russell, gardener to Lord Dean of Guild; Merrilecs, Glasgow; McKenzie, Paisley; J. Anderson, Meadowbank; J. Dobie, Rothesay; W. Paul, Paisley; Downie & Laird, Edinburgh; J. Bryson, Helensburgh; and W. Campbell, Dunoon.

— ON the 27th ult. ST. STEPHEN'S GREEN, DUBLIN, was formally opened as a public park or recreation ground. It comprises about twenty-two acres, and was presented to the City by Lord Ardilaun, who, it is stated, had previously expended upwards of £20,000 upon the place. It is pleasantly laid out, and will no doubt prove a great boon to the inhabitants.

— THE thirteenth annual Exhibition of the CHEADLE HORTICULTURAL SOCIETY will be held on the 27th and 28th inst. in the grounds of Dr. Dodson. Prizes to the amount of £140 will be offered.

— MESSRS. KELWAY & SON, Langport, Somerset, inform us that they have a new and magnificent display of HYACINTHUS CANDICANS, comprising about one thousand plants in full bloom. "Some of the spikes measure from 2 to 3 feet in length, with from fifteen to twenty-five pure white blooms each. The individual flowers are about 2 inches in diameter, and supported on foot-stalks of similar length." The value for decorative purposes of this handsome plant in such exceptionally fine condition cannot be over-estimated either for culture in the borders or in pots.

— ON the 2nd instant the BECKENHAM HORTICULTURAL SOCIETY held their annual Exhibition, by the kind permission of F. Thirkell, Esq., in the grounds of The Hall, Beckenham Road. The exhibits were numerous and generally fresh and vigorous, Potatoes being staged in superior condition. The following were the principal exhibitors:—F. Thirkell, Esq. (Mr. Poffley), J. Moore, Esq. (Mr. S. Nash), J. Goddard, Esq. (Mr. Reed), P. McKinlay, Esq., Croydon Road (Mr. G. Townsend), F. P. Alliston, Esq. (Mr. E. Braybon), H. Wood, Esq. (Mr. J. Braybon), R. Reid, Esq. (Mr. G. A. Steer), and J. Cameron, Esq. (Mr. W. Whitehouse). Messrs. Laing & Co., Forest Hill, sent a large group of plants, and Mr. H. Cannell, Swanley, exhibited cut flowers of Zonal Pelargoniums and Verbenas, which attracted much attention. All the arrangements were very satisfactory, and creditable to the Society's officials.

— AN American contemporary has the following remarks on the beautiful diminutive shrub *EPIGÆA REPENS*:—"Epigæa, Trailing Arbutus, May Flower, and Ground Laurel. This flower is known by these various names in different sections of our country. The plant is supposed to be indigenous to North America, and refuses to be nurtured, preferring the wild fastnesses of Nature. It abounds in luxuriance in the lake region, and also in Plymouth, Mass., where it was the first flower that gladdened the Pilgrim Fathers in their new home. It is still gathered there in great beauty, and large supplies are sent to the Boston market, where it is sold in small bunches during its season, which lasts from ten days to a fortnight." This plant, however, notwithstanding the supposed difficulty attending its culture, succeeds admirably in Mr. G. F. Wilson's garden at Weybridge, as was recently noted in the pages of this Journal; we have also seen it growing luxuriantly in moist peat soil in a garden in the south of Scotland.

LINARIAS.

THE genus *Linaria* comprises many both weedy and ornamental species, and the difference between many of the forms are not very well marked. However, as a rule, this is but of minor importance to the floriculturist. I have never been fortunate enough to meet with a large living collection, therefore I only intend to bring to notice such as I have grown, excluding the more inconspicuous forms. Many of the perennial forms produce long straggling branches, therefore it is advisable that they should be secured to stakes, as it adds much to the beauty of the plant. I purpose starting with the perennial forms. *L. triornithophora* is a tall-growing species with purple flowers solitary in the axil of each leaf, which are placed in whorls. The flowers are large, but the inflorescence is too lax, hence it is more curious than pretty. It is a very desirable species, but is only half-hardy. *L. repens* has very small flowers with bluish veins on a white ground, and attains a height of 2 to 3 feet. *L. purpurea* is very similar in all respects, except that the flowers are purple. *L. genistæfolia* is a small yellow-flowered species, and varies in height from 18 inches to 2 feet. It is not so hardy as the last two species, and is much less common. *L. vulgaris*, though one of the commonest, is beyond all doubt one of the most handsome, the orange palate of its flower contrasting admirably with the pale yellow. As a weed it is about equally as troublesome as *L. repens*, but it might be kept within bounds to a great extent if planted in pots plunged so as to hide the rim. This would also result in producing a denser mass of flowers. The variety *Pcloria*, which has regular flowers with five spurs in place of one, is very interesting. Two years ago I had from Herefordshire a specimen which had one half the

flowers normal and the rest those of *Peloria*. *L. origanifolia* is a dwarf species of somewhat decumbent habit, bears small blue flowers, and is well adapted for the rockwork, but being scarcely hardy it requires the protection of a frame during winter. *L. Cymbalaria* must not be omitted, as it gives a very pleasing aspect to rockwork. *L. pilosa* is somewhat rare; it belongs to the same type as *L. Cymbalaria*, and the flowers are similar, but the leaves are pilose and the habit tufted. It is admirably adapted for rockwork, and ought to be in every collection of alpine. *L. alpina* is an old and well-known species and one of the most beautiful, its blue and orange flowers being extremely attractive. It is of biennial duration, but reproduces itself freely from seed.

Among the annuals there are many of great interest, but I know of none that equals *L. reticulata*, *Desf.*, variety *aureo-purpurea*, and the var. *luteo-aurantiaca*, both found in Algeria, the seeds of which were transmitted to this country in 1876 by Cosson, a French botanist. *L. maroccana*, *Hk. fil.*, is also a very pretty species with purple flowers. I have saved seed of it, and this season I notice a plant among the seedlings with magenta-coloured flowers. It is quite distinct from the rest of its congeners, and I trust that it will ripen its seeds. The last three grow from 12 to 15 inches high. *L. triphylla* is a well-marked species. It varies in height from 9 to 12 inches or more. Its flowers are purple, yellow, and white, which give it a very striking appearance. *L. spartea* bears lax racemes of yellow flowers. *L. Perezii* is another pretty species. It has small yellow flowers, and becomes attractive from its small dense foliage. All *Linarias* thrive best in light soil well exposed to the sun.—M.

AUTUMN MANAGEMENT OF GRAPES.

WHAT "AN OLD GROWER" says on page 52 about allowing the temperature to become too low at night and neglecting to ventilate early in the morning resulting in scalded berries I have no reason to doubt, but why not leave the vinery open all night? It is certainly cheaper than maintaining a temperature of 70° by fire heat, and if the Vines are started early in the season there is no difficulty in having the Grapes ripened. The late Grapes here are now colouring, and as I think that a larger crop of better-coloured Grapes can be secured by cool night temperatures than otherwise, the ventilators are at no time entirely closed. During summer, fire is not employed unless in dull weather.

It is somewhat strange that the Grape Vine should be almost without exception treated as a tropical fruit, when it withstands our coldest winters out of doors, and in the south bears fruit freely. What is said about the necessity of frequent dampings of internal surfaces reminded me of a remark made by a gardener last year when three of us were inspecting his magnificent crops of Grapes. The surfaces of the borders were literally swamped with water, and the gardener expressed his opinion "that any less water applied to the surfaces would result in the crops being scorched and destroyed by red spider!" These Vines were five years old and growing in the natural soil, which was one admirably adapted for fruit-production. If they produce good Grapes ten years after this it will be in spite of the atmospheric moisture supposed to keep them alive. My system is very different from this, yet there is no red spider or thrips on the Vines—only the remnant of a colony of mealy bug, which can now scarcely be called troublesome; yet the Vines are neither syringed nor the surfaces damped. The soil is one on which red spider ought to be at home, and the Vines ought to be worn out in ten years; nevertheless they are carrying better crops to-day than they did five years ago, and I see no reason why they should not continue to do so as long as the vineries themselves stand, provided they are treated to a cool temperature and the soil kept sufficiently moist at all times.

I was much surprised last year when pulling out an old Vine border, which had been made in what was previously an inside pit for plunging Pines, to find one of the Vines, which had always been most robust and prolific, had some of its main roots under the pit and in some rubbish where the roof water was drained. Though the Grapes on this Vine did not finish so well as the others, yet the crops it produced were wonderful. I am more convinced than ever that keeping borders constantly in a moist condition, and keeping the atmosphere of the house constantly changing, are the principal means of maintaining either young or old Vines up to the highest pitch of fruit-production without wearing them out through overcropping. It must be borne in mind that the majority of Grape Vines are cropped to their utmost, and the gardens where the crop is limited to eight or ten bunches on a Vine rod, say 24 feet in length, are very few indeed. When it is considered that ten years of the former system of cropping is sufficient in many cases to exhaust Vines there

is obviously something radically wrong. If young Vines were gently dealt with for the first few years of their existence they would bear well at the time it is generally most required of them—viz., when they settle down to the production of "family" Grapes.

The foliage of Vines has always been considered by good Grape-growers as of the first importance in determining the fruit-producing qualities of the Vines. There are two extremes in the matter of the management of Vine leaves which should always be guarded against; the one is that of allowing the laterals to ramble and interlace all over the roof, and the other that of restricting the laterals to a particular leaf. The main rods are generally too near to each other, and in such cases close pinching is almost a necessity. I consider from 3 to 4 feet distance between the rods no more than sufficient, and I am allowing 4 feet in the case of young Vines lately planted. I may note here that I allow old Vines a moderate lateral growth, so that every available space is filled with foliage, and as the Grapes ripen I cut all laterals in to the main bearing side shoots, and subsequently shorten these back to a leaf beyond the bunch, so that by the end of October each shoot will only have from four to six of the largest leaves. I believe this is conducive to free bearing and healthy growth in two ways. In the first place, whilst the bunches are growing, and until they are approaching ripeness, the amount of foliage left bears them through these stages; and in the second place, cutting away the laterals and shortening back the main shoots are conducive to the keeping of the Grapes, and give the wood every opportunity of maturing thoroughly. These, then, are the principles I adopt in the management of Grape Vines for late bearing: An early start, an atmosphere kept in a healthy condition (not by continued applications of moisture, but by a constant supply of fresh air night and day), borders kept continually moist, and a free and full summer foliage, to be reduced as the Grapes ripen, in order to ensure the keeping qualities of the Grapes and a crop the succeeding season.—R. P. BROTHERSTON.

BORDER FLOWERS—THE CATCHFLY.

IN a well selected and cultivated collection of herbaceous plants there is much to afford pleasure at all seasons of the year, and I have now something to say about the Catchfly. Among the Silences we have some of the choicest ornaments of our borders, rockwork, and similar positions. I am satisfied, however, that they are comparatively neglected, although we have several attractive native species. *Silene inflata* on our hedgebanks is very beautiful. *Silene alpestris* ought to be in all borders and on every rockery; it enjoys the sunshine, but should have thorough drainage. It may be increased by seed sown in the spring in a cold pit, or by dividing the plants after flowering. When well established it is very effective. *Silene maritima* is also a desirable native; the double variety is especially deserving of a place on the rockery. *Silene Schafta* is a grand plant for the border in the autumn. I think this plant might be advantageously employed as a bedding plant. It is in most places a fine addition to the rockery, and is increased by seed in the spring and cuttings in the autumn. One of the brightest species is *Silene pumila*, which ought to be in every collection; it can be increased by seed sown in the spring. *Silene Elizabethæ* is very attractive when well established; it is of dwarf habit and requires care in cultivation, thorough drainage being essential to its success. Seed may be sown in the spring in a cold pit or frame, or the plant may be divided; sandy loam and peat are a suitable compost. There are many others of this charming genus, such as *Silene fimbriata*, *S. pennsylvanica*, *S. quadridentata*, and *S. acaulis*; the latter is seen in all its beauty in its native home among the rocks in the Highlands of Scotland and the Welsh mountains.—CLOVEWORT.

AQUILEGIA CÆRULEA.

THE Columbine represented in the annexed engraving is unquestionably one of the most beautiful forms in cultivation, the delicate tints of the flowers, the graceful foliage, and neat habit rendering it highly attractive. Not only is it a fine border plant, but it also succeeds admirably under culture in pots; and when a number of plants are grown in that way they are of considerable value for the greenhouse or conservatory, where by a little skilful arrangement they may be made to produce a charming effect. The form of the flowers and foliage is fairly well indicated in the engraving, which cannot, however, convey an adequate idea of the plant's beauty owing to the absence of colour. The sepals have long spurs and are of a pale blue tint, which contrasts most pleasingly with the white petals and the rich bright green foliage. There is a form known as *Aquilegia cærulea hybrida*, the result of a cross between *A. cærulea* and *A. chrysantha*, which is also very

attractive. This possesses the pale blue sepals of the former parent, but the petals have become a pale yellow shade, thus clearly indicating the effects of the other species in the cross. It is more robust than *A. cærulea*.

In culture the two referred to above require similar treatment to others of the genus—namely, a moderately warm border of light rich soil, and they can be increased by division or seeds.

For culture in pots the latter mode is preferred, the seeds being sown in April; and the young plants produced should be gradually potted-on, first several into a 5-inch pot, and finally singly into the same size. This is amply large enough for *A. cærulea*, but the stronger-growing form *A. cærulea hybrida* will require pots 6 or 7 inches in diameter. The plants may be placed outside or in cold frames, from which the lights should be removed as fre-

Fig. 26.—*AQUILEGIA CÆRULEA*.

quently as possible. Such, in brief, is the system adopted by Mr. Douglas of Loxford Hall, where Columbines are extensively and successfully employed for decorative purposes, and I have followed the same treatment with considerable satisfaction.

A. cærulea is a native of California, whence it has been introduced within the past twenty years. It was in the opinion of Mr. Burke, a well-known collector of plants, who found it near

Fort Hill, "not only the queen of Columbines, but the most beautiful of all herbaceous plants."—R.

POTTING STRAWBERRY PLANTS.—As the time has now arrived for potting Strawberry plants, the following brief notes may be useful. The soil should be prepared some time beforehand, and

must consist of good turfy loam and well-decayed horse manure, without straw. Much depends upon the manner in which the drainage is attended to. A few broken potsherds should be carefully placed in the pots and covered with coarse crushed bones, upon that lumps of fibry loam may be placed with a layer of soot. In potting, great care should be taken to press the soil very firmly into the pots. The following are in my opinion the best Strawberries for forcing in the order of their ripening—Vicomtesse Hericart de Thury, Sir Joseph Paxton, President, and British Queen.—A. R. P.

SHREWSBURY ROSE SHOW.

THIS most promising and energetic of our lately formed Rose exhibitions is a branch of the long-established Shropshire Floral and Horticultural Society, which may well be held up as a model to most existing sister institutions, inasmuch as she has attained the enviable position of reckoning the balance in her Treasurer's favour by four figures at the close of her spring, summer, and autumn exhibitions—a most remarkable and almost unique result all those who have to do with these matters will be the first, if somewhat sadly, to allow, and reflecting the greatest credit both on the executive and on the many resident territorial magnates of proud Salopia, who by their purse and products lend all the assistance in their power. As usual this unpropitious season, those fitful drenching storms which well-to-do holiday folk dread so much prevailed all day, and was the only disturbing element to an otherwise complete success, though the Exhibition was held in a roomy well lighted and ventilated hall. The Hereford Roses carried off most of the chief prizes, and in this respect the Society was liberal, as not one class was reserved locally. Messrs. Cranston & Co. had splendid blooms, and took first prizes for both the forty-eight single varieties and thirty-six triplets. To the latter a special condition was attached that each variety should be exhibited in three different stages of development—an idea, on so large a scale at least, we believe the public will consider more erroneous than commendable. Messrs. Dawson were a good second in each of the above classes. There was no competition for the third prize. In the classes for thirty-six varieties, from which competitors in the two former classes were excluded, Mr. Jowitt, Hereford, was first with a fine bright collection. Mr. Hawtreys carried off the second prize after a very close contest with Messrs. Dickson & Sons. In Class 24, single varieties, Mr. Jowitt was again first in order of merit, while Messrs. Dickson & Sons and Mr. Hawtreys changed places. In the Tea and Noisette class a very creditable competition took place considering how adverse the late winter and summer have been to these loveliest and most delicate of Roses. Five exhibits, of very fair colour and freshness, faced the Judges, Messrs. Cranston taking first prize easily with a neat collection. Mr. Hawtreys was second, and Messrs. Dawson third.

In the class for twelve Roses of any one variety Mr. Jowitt carried off the first prize with H.P. Alfred Colomb. Your reporter had not the privilege of seeing this gentleman's much-vaunted collection of this Rose at Manchester; but at Shrewsbury it was the general opinion that twelve more shapely, bright, and at the same time level and immense, blooms were never staged. Messrs. Cranston & Co. took second honours with that vigorous old variety Mdle. Marie Rady, and magnificent specimens they each were, enhancing the well-earned triumph of the victor, while Messrs. Davison & Co. secured third prize with another collection of fine H.P. Alfred Colomb in a remarkably good class. Messrs. Cranston & Co. were awarded a certificate of merit for their new Rose Mrs. Jowitt, a seedling of which this firm has already an immense stock, so highly have they long valued its merits. It is a cross between Mdle. Marie Rady and Duc de Rohan; the vigorous foliage and wood of the latter it closely resembles, while in shape and substance it may be said to follow a well built-up extra bright Alfred Colomb.

The Rev. C. H. Bulmer and Mr. Griffiths, Tillington Nurseries, Hereford, acted as Judges. All official arrangements were carried out by Messrs. Adnitt & Naunton, the energetic and obliging Hon. Secretaries, in evidently the most practised and successful manner. The system of reversed cards being affixed to each exhibit was followed as at the metropolitan exhibitions; and with the single exception of the Judges being requested to obey the absurd, and it is to be hoped the purely local, custom of retiring from the Exhibition Hall until their services were required, every detail was most pleasantly and efficiently carried out. It only remains to add that if the National Rose Society's Provincial Meeting is not held in Shrewsbury next year, from the remarks your reporter heard transpire, it will not be the fault of the Shropshire Horticultural Society, who are most ambitious to secure that honour, and are fortunate enough to possess an unusually capacious well-lighted Market Hall, admirably adapted for the purpose.—THE HEREFORDSHIRE INCUMBENT.

PORTRAITS OF NEW AND NOTABLE PLANTS.

BIGNONIA CAPREOLATA var. *ATRO-SANGUINEA*.—"Bignonia capreolata is one of the loftiest climbers in the forests of the Southern United States from Virginia to Florida and westwards to the Mississippi, where it ornaments the rocks and trees by its luxuriant foliage and (usually) orange-yellow flowers. The Ame-

rican name of Cross-Vine is given in reference to the wood of the stem, which on a transverse section presents the form of a cross."—(*Bot. Mag.*, t. 6501.)

ODONTOGLOSSUM ODORATUM.—"A many-flowered sweet-scented species of *Odontoglossum*, discovered in the humid and gloomy forests of the Sierra Nevada of Merida, at an elevation of 7000 to 8000 feet, by Linden. It belongs to the section with *O. Hallii*, *Lindl.*, *O. nævium*, *Lindl.*, and others which constitute the genus *Odontoglossum* as first known and described. All have slender spreading ears at the top of the column, which sometimes end in bristle-like appendages."—(*Ibid.*, t. 6502.)

POLYGONUM CUSPIDATUM.—"P. cuspidatum is a native of Japan, and there is in the Kew herbarium a very similar plant from North China, collected by Dr. G. Shearer at Kieu Kiang; the specimens of this are, however, not sufficiently good to pronounce upon, and the racemes from which the flowers have fallen are much shorter and more fasciated. This species was introduced into England many years ago; it has been cultivated for a quarter of a century at Kew, to which it was, I believe, sent from Holland. Like the rest of the half-shrubby species, it flowers very late in the season, and is dioecious. It is a tall, glabrous, bushy herb, 6 feet high, with innumerable stout, branching, angular, red-brown leafy stems, rising in a tuft from an underground rootstock which sends out innumerable runners."—(*Ibid.*, t. 6503.)

CAMPANULA FRAGILIS.—"Often have we heard travellers from Italy expatiating upon the beauty of the spots which are enamelled with the bright blue flowers of this interesting stranger, but it was never our good fortune to see it alive till we met with it in the garden of Mrs. Marryatt at Wimbledon. According to Alphonse De Candolle this plant is a native of the evergreen region of Italy south of latitude 41°, and struggles through the lower woodland region up to the upper limits of the Beech, about 3000 feet above the sea, growing in exceedingly dense tufts on limestone rocks. However, specimens have been gathered by Mr. Grove at 5000 feet elevation, in the valley of Orfenda of the Abruzzi. A glabrous, hairy, or pubescent decumbent herb, with slender branches 6 to 10 inches long springing from a woody perennial rootstock."—(*Ibid.*, t. 6504.)

BERBERIS BUXIFOLIA.—"Berberis buxifolia ranges from Chili to the Straits of Magellan, and probably further south, but in Fuegia it is replaced by *B. ilicifolia* and *B. microphylla*. It was introduced into cultivation by seeds collected by Mr. Anderson, the botanical collector attached to Capt. King's survey of the Magellan Straits, which were raised in Mr. Low's nursery at Clapton. It has long been cultivated at Kew. The berries are eatable. It is an erect, glabrous, rigid shrub."—(*Ibid.*, t. 6505.)

INDIGOFERA ANIL.—"This, the indigenous Indigo of the West Indies, is the representative of the *I. tinctoria* or Indigo of the Old World; but both of these plants having been cultivated for some centuries for the extraction of the well-known dye, are now naturalised in the tropics of the Old and New World. Of the two species, *I. tinctoria* was known for its product from very early times, being in use by the Egyptians and described by Dioscorides; whereas the *I. Anil* could not have been known in Europe or the East until after the discovery of America. An Indigo appears, however, to have been used by the natives of the New World before it was brought into competition with the plant of the Old; for Sloane (*Hist. Jam.* vol. ii. p. 37) says, 'Robt. Tomson ap. Hakl., p. 454, found it about Mexico, where it is used to dye blue.' An erect shrub, 3 to 6 feet high, faintly hoary, with appressed hairs, which are attached by the middle."—(*Ibid.*, t. 6506.)

ST. IVES (HUNTS) HORTICULTURAL SOCIETY.

THIS Show was held in the grounds belonging to Henry Goodman, Esq., on Needingworth Road, and it was considered to be the finest since the inauguration four years ago. We congratulate the promoters upon the rapid strides made, which is evidenced by the increased number of exhibitors. The productions were arranged in three large tents kindly lent by Bateman Brown, Esq., J.P. If the Society progresses in the same proportion another tent or two must be provided in the future.

The leading features of the Show were the Rose classes, for which the following prizes were kindly given by the Mayor, John Wadsworth, Esq. For twenty-four distinct varieties the first prize was taken by A. G. Soames, Esq., Innam Park, Bourne, whose blooms were greatly admired; the second by Messrs. Paul & Son, Cheshunt; and the third by Mr. W. Farren, Cambridge, whose blooms keenly contested for second honours. For distinct varieties open to all amateurs Mr. Soames again came first, the Rev. E. L. Fellowes of Wimpole Rectory being second. The following celebrities also exhibited—Messrs. E. W. Cooper, House, L. Curtis, J. Smallbones, and Burton.

For twelve distinct varieties, confined to amateurs members of the Society, Mr. T. Seckings, Earith, took first prize, and Mr. R. M. Copley, St. Ives, second. The principal exhibitors in the amateurs' flowers

were the Rev. C. Hoskyns, Messrs. Warner, Copley, Chapman, Baker, Carroll, and Woods. In table decorations the Misses Kings, Wadsworth, and Hewlins, were the chief prizetakers with arrangements which were greatly admired.

In vegetables Messrs. Copley, Wise, Adams, Woods, and Chambers obtained the chief honours. Not the least important feature of the Show was the cottagers' classes, which still continues to be the chief aim of the promoters to foster. The vegetables and flowers were extremely creditable to all the exhibitors. Amongst the Potatoes we noted a new seedling raised by Samuel Russell of Holywell, and called the Holywell Seedling, which appeared to be a promising variety. The weather was all that could be desired.

A DAY IN BEDFORDSHIRE.—No. 2.

AFTER a stroll through the estate of Old Warden, described last week, an evening visit was paid to

SOUTHILL PARK.

This is the residence of Samuel Whitbread, Esq., M.P., whose richly-wooded demesne is of great extent. In the park are some grand old Cedars of Lebanon, and the deciduous trees are numerous and large; it also contains a fine sheet of water. The pleasure grounds are extensive, and grand old Conifers with rare deciduous trees adorn the lawns, while there are borders of Rhododendrons and dense thickets of evergreens; the Yews are evidently of great age, and almost form arcades over the walks and drives. Adjoining the large mansion is a conservatory, which with rockwork, Ferns, Palms, Camellias, &c., might be rendered highly ornamental. At present its principal occupants are some remarkable flowering specimens of *Cordyline australis* reaching to the roof, their trunks being 18 inches in circumference. On the back wall is a grand example of *Rhynchospermum jasminoides* in superb condition, bearing thousands of trusses of flowers most valuable for cutting. A *Pelargonium* on the same wall, apparently *P. cucullatum*, or a variety of that species, yields also an abundant supply of flowers. But the chief feature of Southill is the kitchen garden, which is about six acres in extent, every portion being closely cropped. Vegetables of all kinds were in splendid condition, and Currants, Gooseberries, and Strawberries were bearing immense crops, but Apples and Pears were sparse. Plums on the west aspect of a wall were plentiful, on the east aspect there was scarcely any fruit. Strawberries were indeed a remarkable crop, that of the variety Wonderful being prodigious, the fruit ripening to the point, which is not always the case with this variety. President was also exceptionally fine. Mr. Landers, the gardener, is a great advocate for mulching, the ground being covered several inches deep with bracken early in the season, and thus the roots of the crops are kept cool and moist, and little or no artificial watering is required. The glass structures are old, and the Vines have passed the zenith of their vigour; the best, however, is made of them, and good culture prevails throughout the establishment.

MARKET GROUNDS.

These are extensive in that district of Bedfordshire within easy reach of Sandy station, and vegetables are largely and excellently grown for the London market and northern towns and cities. The tremendous hailstorms that brought such great losses to many cultivators, almost ruin to some, in the Thames Valley, proved beneficial to Bedfordshire growers in a manner that the general public would scarcely anticipate. For some years there has been great competition between the market gardeners of the two districts for London manure; but since the storms that proved so costly the Surrey and Middlesex men have not been able to purchase so largely, and consequently the manure has been unusually cheap, and greatly increased quantities have been purchased for the Bedfordshire farms and gardens.

The soil is of medium texture, rather light than heavy, free to work, moderately deep, and resting on gravel, and the district is sheltered by rising ground, hills crested with woods on the eastern side trending to the north. These natural advantages are supplemented by a superior system of cultivation. Manure is applied to the land liberally, and is appropriated by the crops, not by weeds, which have had more to do with the late and present depression in agriculture than has yet been fully appreciated. Corn crops, Potatoes, vegetables, and the raising of such seeds as Onions, Mangold Wurtzel, Turnips, and Carrots, appear to alternate, and all are good, most of them splendid. The holdings are generally small—from one to four or five acres, and their rental is £4 to £6 per acre. At this rental the tenants appear prosperous, and the landlords are probably satisfied. The secret of the success is that each holder does not appear to have more land than he can manage well. Small farms generally are perhaps not the most highly cultivated, but that is because, small as they are, they are beyond the means and capital of the tenants to cultivate profitably, and it is certain that many large farms are suffering now

from the same cause. They are, in fact, too large, and the lowering of the rents of such farms will neither make the owners nor tenants rich, while the consuming public have also a share in the disadvantages inseparable from a system where the capital of the cultivator is disproportionate to the acreage of the land. The Bedfordshire holdings referred to are more like gardens than farms, and it would be well if there were more such, and there is no reason why there should not be in every, or nearly every, county in England.

The corn, Potato crops, and breadths of seed are splendid, but the heads of Onion seed are not generally of great size. Many acres of Onions are grown for producing bulbs. The seed is mostly sown broadcast, and the weeding is done at so much per acre, the men using short one-handed hoes; but in most instances some other crop is grown with the Onions, the seed of both being sown on the same ground in proper proportions. Sometimes the second crop, to mature in the autumn after the Onions are harvested, is of Parsnips, in another breadth Carrots, and in a third Parsley, the plants in each case being thinly disposed. Parsley thus grown in open fields endures severe frost much better than that grown more closely in the rich soil of sheltered gardens; and when the produce realises 10s. to 15s. a pound, as it has done in London from December to March during the past three years, the crop pays all expenses and the Onions go for profit. Between the rows of some early Potatoes are planted Brussels Sprouts and Kales, and also Scarlet Runners, all of which are lucrative. Thus every provision is made to ensure a good return, and complete failures are reduced to a minimum.

"Ridge" Cucumbers are grown by the acre, but not on ridges. The ground is simply heavily manured, and well dug and stirred, the Cucumber seeds being sown about the middle of May. Thick rows of Onions for seeding are planted at intervals of 5 or 6 yards, the growth affording shelter for the Cucumbers. Sometimes rows of Rye are sown for the same purpose; but the best Cucumbers I noticed were in small squares bounded by rows of early Peas. Vegetable Marrows are grown in the same way. Cucumbers were last year a failure, and this year they are not promising, but with fine summers and autumns the crops are very profitable. On the whole the garden-farming of this district is most creditable to the cultivators, whose forethought and industry might well be copied in many other localities. But I am now approaching a place of interest, and of which the readers of the Journal will be glad to hear something—namely,

THE EXPERIMENTAL GARDEN AT GIRTORD.

Mr. Laxton has done so much in the cause of horticulture by raising standard varieties of Roses and vegetables, that a brief reference to this garden cannot fail being acceptable to many readers of the Journal. It may be well, however, to commence with a caution. Not a few votaries of gardening are enthusiastic, commendably so in many instances, and it is no task to them to travel long distances to see anything grand or imposing in their favourite pursuit. There is nothing of this nature at Girtford, and no long pilgrimages can be advocated for the purpose of inspecting its beauties. In the first place it is a new garden, and in the next nothing of an ornamental nature is attempted: it is merely the scientific and practical laboratory of a skilful man. When the great trial collections of Strawberries were fruiting, the Roses blooming, and the Peas and Beans in full bearing, the garden possessed some attractions, and it was unquestionably full of interest.

It is just a plain enclosure of three acres, something like a cottage garden by the wayside of the village, and extending back and widening into a field. The north side is bounded by a wooden fence, on which fruit trees, mostly Cherries, are being trained, with Tea Roses at the foot. It is separated from the village simply by a low wall, and on the field or garden sides by galvanised wire. The soil is variable, remarkably so for so small a plot, but as it is all good this is an advantage for experimental purposes. The "Experimental" is undoubtedly admirably situated, being in a locality noted for its commercial gardening, and, what is important, is contiguous to a line of railway.

It is not a garden of fads where all sorts of vague experiments are tried for self-gratification, and, as such gardens usually are, a scene of beautiful disorder. On the contrary, a very practical air pervades it, and order and good culture prevail throughout. It is a commercial and scientific establishment conducted by a practical man—a gardener by instinct and intuition, diligent worker, a good cultivator, a close observer, and a careful recorder of the points and merits of varieties of plants and vegetables with their pedigrees.

The plan adopted appears to consist in making crops essentially useful and always in demand give an immediate return, or in plain terms to "pay" for the labour involved in the production

of new varieties of decided novelty and sterling merit. Remembering Mr. Laxton's success as a hybridiser of Peas, Roses, and Strawberries, and noting also the condition of the garden and the work in hand, there is no reason why the undertaking should not prove a success. To all outward appearance the prospect is good, and certainly there were some profitable crops in the garden at the time of my visit. For instance, early Potatoes, a fine yield, were being dug and packed for market; this crop alone would be lucrative, but in addition a valuable second crop will be taken from the same ground. Scarlet Runners had been sown at intervals of about 18 inches between the rows of Potatoes, the plants to be grown in bush form by occasionally pinching the stems. They were flowering freely before the middle of July, and are sure to be profitable. Several varieties of Potatoes are being tried, one that promises to be very useful for "double cropping" being the American Beauty of Hebron, which is much dwarfer than the Early Rose and is earlier, while it otherwise much resembles that variety. It was too early for any estimate being taken of the varieties generally, but not too early for seeing that the disease had slightly affected a few of the plants; but as the affected haulm is removed immediately the much-dreaded symptoms are seen no material loss is anticipated.

Of Strawberries there is a great collection in short rows for purposes of comparison, all the new and most of the best old English and continental varieties being represented. Hybridising and seedling-raising is also going on. One rather remarkable cross had been effected—namely, between the fine variety Dr. Hogg and the common wild Strawberry of the woods—the former the seed-bearing parent. The variety selected as the result of this cross has the form of leaf of Dr. Hogg with its dark green colour, and the slender proliferous creeping runners of the wild Strawberry. The fruit is intermediate between the two, being nearly an inch in diameter, round, resembling in shape Trollope's Victoria, red, and with a curious blending of the flavours of the two parents. This variety is not considered "good enough" to be increased and distributed, and will only be employed for crossing purposes. Seedlings were being raised in pots. It is not likely that much earlier varieties than those now in commerce can be produced, but a good Strawberry decidedly later than our present varieties would be an acquisition; or one of a continuous bearing character, and the raising of these ought not to be an impossibility.

Peas are a feature of the Garden, Mr. Laxton pursuing the work of crossing with diligence, and the work of selecting a very few from a great number of varieties is no easy task, and can only be done with advantage by those having a wide knowledge of all the existing varieties. The temptation to retain too many must be great, since so many are good, but only those undoubtedly distinct are kept for trial a second time. There are Peas of almost all attained heights, sizes, and colours, from the diminutive Minimum only a few inches high with a mass of pods, to such imposing forms as Superlative Improved, Telephone, and others which cannot be named; but the Pea of the Garden is John Bull that is fully referred to on another page. There are Peas with black pods and white pods, and mottled pods, and, of course, all shades of green; in fact to the casual visitor the collection is a little bewildering. The pedigrees of all the varieties and their qualities are carefully and accurately recorded, and everything is done in a systematic manner and with a clearly defined object. Beans are receiving similar attention and also other vegetables, of which probably something will be heard by-and-by.

Roses, as may be expected, continue to be crossed and raised. There are thousands of seedlings, not a few of which are flowering, from seed only sown in the spring of the present year. Immediately a bud can be had from a variety of promise it is inserted in a stock for fully testing its merits. And here special knowledge is again requisite, for Roses that are only semi-double at first often prove eventually to be grand varieties, while those that are double at first frequently become so close and firm afterwards that they do not expand freely. Mr. Laxton has already raised more Roses of sterling merit than any other raiser, and further successes may with much confidence be expected to follow the efforts of this skilled and careful operator and indefatigable worker.

Omitting much that is worthy of mention in the "Experimental," it may be remarked that the Garden is just what its name implies. No mere fancies are indulged in for making a show. It is not a garden of beauty but of utility, and it is not a public but a private garden.—J. WRIGHT.

PRIMROSES AND COWSLIPS.—A lady from Jersey tells me that there are plenty of Primroses in the island but no Cowslips, and that if Cowslips are taken over to Jersey they soon change to

Polyanthuses—i.e., the flowers become larger and assume a pinkish hue. This agrees very nearly with the statement of the Devonshire people, that Cowslips if taken there soon change to Primroses.—AMATEUR, *Cirencester*.

TWO SCOTCH ROSE SHOWS.

AGAIN it has given me great pleasure to attend the rosy gatherings of the Galloway and West of Scotland Rosarian Society's Shows, for although minor affairs in comparison with many of those which I have the happiness of being present at, yet in one respect—viz., hearty love for the Rose, they will yield to none; and although, as in all other things of a similar character, one has to notice changes and losses, yet it is a pleasure to meet friends again and to find heartiness in love of the Rose not diminishing but increasing. In one respect the Exhibition this year differed from others previously held—none of the English nurserymen were present. Messrs. Dickson and Co. of Newtownards, and Mr. Dickson of Belmont near Belfast, however, were present in force and worthily maintained their reputation.

There has been a marked difference between Scotland and England on the point of weather this year, for while we have had a season in which Roses have been behindhand in point of time and characterised by incessant thunderstorms and deluges of rain, in Scotland they were more forward than were in the south-east of England. The hay was all in, Roses were past their best, and the rivers quite low; in fact in some places watering Roses had to be resorted to. First in order was

THE GALLOWAY ROSE SHOW.

This, which has been hitherto held at Newton Stewart, was this year held at Stranraer, the extreme point of the peninsula which forms that portion (consisting of Wigtonshire and Kirkcudbrightshire) of Scotland known under the name of Galloway, Newton Stewart being about the centre and Castle Douglas the inland extreme of it. The change did not seem to be a happy one, for although the day chosen for the Show was that on which the Galloway Agricultural Society held theirs, there were fewer attendants than at Newton Stewart, and certainly fewer Roses; and I do not think, although Stranraer is a thriving place, that it will soon again have a Rose Show.

Messrs. Dickson & Son of Newtownards were first in the open class with a very fine stand, in which were the following—Dupuy Jamain, Marie Rady, Marie Verdier, apparently a good Rose of a peculiar shade of colour; Baroness Rothschild, Mrs. Laxton, Madame Bernet, Dr. Sewell, Eugénie Verdier, and Louis Doré, a promising new Rose. Mr. Smith was second with a good stand, in which the most noticeable were Thomas Methven, Gaston Levêque, apparently a good new Rose; Ferdinand de Lesseps, Baron Haussmann, Léon Renault, Le Havre. Mr. Smith was also first in the twenty-four class confined to local growers; in this stand were fine blooms of Mons. E. Y. Teas, Penelope Mayo, Sophie Fropot, and others. In the class for twenty-fours, confined to amateurs and gentlemen's gardeners, Mr. J. Richardson of Tondraghee Gardens was first. In his stand, besides other well-known favourites, were good blooms of Mdlle. Gabrielle Luizet, François Louvat, Madame Nachury, and Baronne de Rothschild, Cheshunt Hybrid, Boieldieu, Comtesse de Paris, very bright; and Comtesse de Serenye, clean and good. In the class for twelves Mr. P. Lennox was first, A. Colomb, La France, Dr. Andry, were the best blooms; and Mr. McMunro was first in the class for amateurs only. He had good blooms of Madame Charles Wood, Etienne Levê, Maréchal Niel, and Marie Rady. The other classes do not call for any particular comment. Cottagers were poorly represented, and the bouquets were indifferent, except one, which consisted of seventy-five distinct varieties of herbaceous plants.

It was indeed a strange experience for me to revisit a place in which fifty years ago I had spent some very unhappy months as a half-starved schoolboy, and where I had not been since; still more to revisit, as I did the following day as the guest of my good friend Provost Stuart, Brodick Bay and Lamlash in the island of Arran—places I used in those long-past days, when many a time I was thankful enough after a stormy cruise to find myself in shelter. And how retentive memory is of those early days! As we steamed into Brodick I could without difficulty call to mind the Castle, and the road to Kilmichael, where blackcock and grouse used to abound, and where my good father used Col. Fullerton's property, bringing home many a weighty bag. And now! Well, if the times have not changed, which assuredly they have, we at any rate have done so.

THE WEST OF SCOTLAND ROSARIAN SOCIETY'S SHOW

Was held in the grounds of The Hermitage at Helensburgh, and was remarkable for the large number of amateur exhibitors and the general good character of the blooms, although, as I have said, in some instances the season was past. Notably was this the case with Major Denniston's flowers, which had won high honours at Edinburgh, and which last year occupied so conspicuous a place, but were now over. Messrs. Dickson & Son of Newtownards were first in the open class for nurserymen, their stand comprising amongst others good blooms of Etienne Levê, Capitaine Christy, Annie Wood, Charles Lefebvre, and Mrs. Laxton. Messrs. Hugh Dickson of Belmont, Belfast, was first in the class for thirty-six with a fine stand consisting with others of the following—Marquis of Salisbury, Charles Lefebvre, Barthelemy Joubert, and Horace Vernet. Amongst amateurs Thomas Watson, Esq., of Row (gardener, Harry Lester), was

the most successful competitor, while my friend Mr. Whitwell of Darlington carried off the prize for twenty-four open to all with a very excellent stand. One other prominent feature of this Exhibition is the large number of bouquets. On this occasion there were no less than 238, and it was amusing to see the competition there was to get these and the Rose blooms after the Exhibition had closed, for a regular auction was held, and the whole, which goes to the benefit of the Society, amounts to a good round sum; and those persons who hold the notion that the Scotch have no humour in them would have been not a little surprised to have heard the shouts of laughter with which the auctioneer's sallies were greeted.

As is usual on these occasions the Show was formally opened at half-past one o'clock, and Provost Stuart did it admirably and with excellent taste, while at the dinner he presided in that genial and hearty spirit which always makes a dinner go off well. The Society is in a flourishing condition, and with such active officers its prosperity is assured.—D., Deal.

OPHIOGLOSSUM VULGATUM VAR. AMBIGUUM.

THE accompanying illustration is a faithful representation of this rare Adder's-tongue Fern, which was discovered by Mr. W. Curnow some years ago at St. Martin's, one of the Scilly Isles. Some botanists regard it as a mere form of the common *O. vulgatum*, and others as identical with *O. lusitanicum*. I wrote to

Fig. 27.

Mr. Curnow on the subject, and the following is his reply:—"In regard to *Ophioglossum ambiguum*, I think it is generally considered distinct from *O. lusitanicum*, and that it is only a variety of *O. vulgatum*. The season of fruiting is in accordance with this. If, on the other hand, as some say, this is found at Scilly in fruit in January, I should regard it as identical with *O. lusitanicum*. Living plants of the latter that I had from Jersey or Guernsey last year did not, as far as I could perceive, differ in appearance from the Scilly plants, but the former fruit in the early spring months, whereas the latter fruit in May and June. The question seems to be, Does it fruit twice in one season?—W. CURNOW."

It must be remembered that the range of *O. lusitanicum* is very extensive, inhabiting the sandy coasts of Europe and Africa washed by the Mediterranean, extending to the Canary Isles and Madeira. I may also add that the time of fruiting of those found at Scilly agrees exactly with those that are found in Portugal—viz., May and June, so that probably the Scilly plants are the typical *O. lusitanicum*, and the Guernsey plants the varieties.—W. ROBERTS, Penzance.

ACER NEGUNDO VARIEGATA.

AMONGST white-leaved deciduous trees or shrubs for associating with other colours this has no equal, and it is surprising that it is not more planted in flower gardens, about pleasure grounds, carriage drives, and such places. It is also worth growing in pots for conservatory decoration. I lately saw a fine quantity of it in this way in Messrs. Veitch's Nursery, Chelsea, as a foreground to the banks of fine, healthy, dark green-leaved Camellias which are cultivated to such perfection in one of the entrance

corridors to these excellent nurseries. As seen against the dark green leaves it was very effective. As noticed at page 29, the bed of blue Delphiniums and this Acer in Battersca Park was most pleasing when I saw it three weeks ago.

It grows equally well with Mr. T. S. Ware at Tottenham, but there it is not seen to the best advantage, as it is planted chiefly near the tops of hardy plant mounds with no other foliage near. In pleasure grounds no one could err in planting it about the margin of shrubberies.—J. M.

HARDY FRUIT GARDEN.

WASPS are extremely abundant this season, and although there is little of the finer fruits to tempt them, the smaller kinds are not free from their depredations, hence it becomes imperative to destroy all the nests possible. Commence in good time to trap the insects by means of bottles half filled with well-sweetened beer or cider, and suspended near the places the wasps frequent. If the wasps taken are numerous the bottles should be cleared every morning.

It may seem superfluous to make any remarks about ripening fruit, but its generally scarcity render more than ordinary care necessary. Apricots are fine, only Oullins Early, St. Ambrose, and Moor Park have fruit to which ants pay assiduous attention, but guano sprinkled at the base of the wall occasionally will drive them away. Plums on wall-trained trees are swelling well, and in some instances are a fair crop, but pyramidal trees are almost a failure, the fruit having dropped except Rivers' Prolific, an excellent early culinary Plum. The leading shoots of wall trees should be regularly nailed or tied-in, allowing room for the swelling of the shoots, continuing to remove or stop superfluous or foreright shoots, avoiding overcrowding, so that the young wood retained may derive the benefit of light and air. Grape Vines on walls should have all superfluous shoots removed, and the laterals well pinched back, so as to admit sun and air to the wood, keeping the fruit close to the wall, the berries being carefully thinned out on each bunch. Ripening fruit of Apricots and Peaches must be examined daily, and when mature it should be removed carefully, as undue pressure will injure the flesh and decay speedily ensues. The fruit is better for being allowed to lie for a day or two on padded shelves in a well-ventilated fruit-room. Protect Morello Cherries with nets from birds, and after hanging a time this fruit is much esteemed by some for dessert, and it forms acceptable dishes in September and early October. Bushes of Red Warrington or any other late Gooseberries, together with Red and White Currants, should be covered with nets to preserve the fruit until a late period. Mats from excluding air and light and engendering damp should never be used. Hexagonal netting is the best material for the purpose. Continue to layer runners of Strawberries in pots for forming fresh plantations, and where runners are not required they should be removed from plants in bearing.

FRUIT HOUSES.

Melons.—Give all possible attention to the batch of plants recently planted out for affording ripe fruit in October, encouraging them by every means to make a strong and quick growth, affording a minimum temperature of 70° to 75°, and a maximum of 90° to 95°, with a moist atmosphere, and shade only to prevent flagging. Train with one stem only, allowing them to advance well up the trellis before stopping, and pinch out all laterals between the bed and trellis directly they are visible. Earth-up the roots of plants which have set the fruit; afford the needful support to fruit hanging beneath the trellis; and be careful in the application of water when the fruit is ripening, not, however, permitting flagging. Late crops in pits and frames should have a steady bottom heat to enable the fruit to swell off freely, applying a good lining if necessary, and afterwards admitting a little air constantly to allow rank steam to pass off. Canker is unusually prevalent both at the collar and in the old growths. Employ no more water than is absolutely necessary to maintain the plants in healthy growth, and ventilate constantly in dull wet

weather, rubbing out the canker with fresh-slaked lime. Cracked fruits result from excessive vigour and too much atmospheric moisture. Cut the stem about half way through a joint or two below the fruit, and ventilate freely, reducing the supply of water to the roots without allowing severe flagging.

Cucumbers.—The plants for autumn fruiting should be placed out at once, observing the same conditions as for late Melons, except that the temperature need not be so high by 5°. In pits and frames keep the foliage well thinned, the old growths constantly removed, and in laying-in young growth be careful to add a few handfuls of fresh soil where convenient. Close the lights as early as is consistent with the well-being of the plants, maintaining a free and fruitful growth.

Figs.—The second crop of fruit on early-forced trees will now be ripening, and the supply of water at the roots must be carefully regulated so that the flavour of the fruit be not deteriorated. Syringing the foliage must also cease, and a free circulation of warm dry air afforded, which should be continued to the trees after the fruit is gathered, as it is of the utmost importance that the wood be thoroughly matured. The early-forced trees in pots should when the crop is gathered be continued under glass until their growth is mature, similar remarks applying to trees in pots intended for early forcing for the first time. The young trees obtained from cuttings in spring, and intended for forcing in the second or third year of growth, must be attended to in pinching off the tops of all the strongest shoots to form a symmetrical head in the first year of training. The latest-forced trees which ripened their first crop in June will now be swelling a second crop, and must be thinned where too crowded, the swelling being encouraged by syringing the trees twice daily, keeping the roots well supplied with liquid manure and the mulching constantly moist. Maintain a brisk temperature by closing early, and after the fruits commence ripening a circulation of dry warm air constantly will be needful. Steady attention must be given to stopping and tying, avoiding overcrowding the young shoots, as they will, especially vigorous shoots, need all the light that can be secured to them.

Cherry House.—Trees subjected to forcing for several years successively are liable to premature growth, which is best arrested by fully exposing them to the air and light. Red spider is not very partial to the leaves at this stage, but the foliage should if necessary be washed occasionally, and black fly must be eradicated by the application of tobacco water. The border must not be allowed to become excessively dry, but receive copious supplies of water when necessary, and an application of liquid manure will assist in plumping the buds. Trees in pots will require frequent attention with water, and the foliage must be kept clean, so as to maintain it in a healthy condition as long as possible.

PLANT HOUSES.

Orchids.—The temperature of the East India house may range from 75° to 85° by day, and average 65° at night; the temperature of the Cattleya house may be 5° less. Continue the same general treatment of plants in the East India house. The shading in the Cattleya house may be almost dispensed with, except when the sun is very bright. Cattleyas making their growth should receive every possible encouragement. *Calanthe vestita*, *C. Veitchi*, and *C. Warneri* should not be any longer shaded, but be watered liberally at the roots for some weeks to come, and occasionally with weak liquid manure. *Dendrobium nobile*, *D. Cambridgeanum*, and many other *Dendrobes* will have completed their growth, and should be placed in a light position, where they can ripen their new growths. *Odontoglossum vexillarium* will now be breaking again, and may be repotted, and water afforded according to its requirements. Plants of *O. Phalaenopsis* requiring more root room should be attended to at once, avoiding overpotting, and affording extra drainage, watering freely. *Thunias* should be moved to a light airy house, where they will ripen off; but they must still be watered. Thrips are often troublesome at this season; fumigate frequently, and wash the foliage with a solution of soft soap, and afterwards sponge with clean rain water.

Stove.—Gardenias that were struck during the spring for winter flowering should be well attended to, not allowing them to become root-bound, but shift into pots 7 or 8 inches in diameter, according

to the vigour of the plants, and keep them near to the glass in a moderately high temperature to secure well-matured growth before autumn. Few flowers are so acceptable as Gardenias, and no plants more easily grown; the chief point is to keep them free from mealy bug, the plants being frequently scrutinised for them, and given when needful a thorough cleaning. The fragrant *Toxicophloeæ spectabilis* is also useful, the flowers being produced freely in corymbs. It requires a cool stove or intermediate house, succeeding well in sandy peat.

Hoya bella as a bouquet flower when mounted is one of the most beautiful, and as a basket plant is unrivalled. It may be grown in pots plunged in baskets lined with moss, and does not require much root space, succeeding in sandy peat or light fibrous loam. In late summer *Æschynanthuses* are very effective suspended in conservatories; they also may be grown in pots and plunged in baskets lined with moss. Flowering as they do when flowers are scarce—viz., in late summer and autumn—it is remarkable they are so seldom seen, especially as they are of easy culture. *Tillandsia Lindenii*, with its intense blue flowers, is very effective, and small plants are very useful. It is increased by suckers, which are produced after flowering; these when large enough should be taken off, and placed singly in small pots. Sandy peat, well drained, and a light position suits it.

Allamandas will continue flowering until a late period, providing they be regularly supplied with liquid manure. *Bougainvillea glabra*, whether in pots or planted out, should be similarly treated. Early-flowered *Gloxinias* should be gradually dried off by withholding water and keeping the plants in a light airy position until their growth is matured, when they may be stored away either in the pots or in boxes in slightly damp sand in a temperature of 45° to 50°. Later-blooming plants should receive liquid manure occasionally. *Achimenes* likewise should be afforded weak liquid manure occasionally; and the bright scarlet *A. coccinea* and *A. ignea*, if kept near to the glass and in not too high a temperature, will flower until an advanced period in autumn. *Gesnera exoniensis* and *G. zebrina splendens* should have weak liquid manure afforded them to secure sturdy growth and fine spikes of bloom.

Stove plants that have been placed in the conservatory will succeed so long as the weather is warm, and the precaution is taken not to supply too much water nor to ventilate too freely in dull weather. When the nights become cold valuable specimens should be returned to the stove, or they will receive a check likely to interfere with their future welfare.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Lifting Potatoes.—It is to be hoped that many have profited by the advice frequently given in the pages of this Journal, to the effect that all early and second early Potatoes that have perfected their crop of tubers should either be lifted or have their haulm drawn from them before becoming diseased. Probably there are some who have been deterred from adopting this sensible practice, as the growth this season is unusually vigorous, and giving the appearance of still being growing, when in reality the tubers are fully grown, or at all events sufficiently so to admit of being lifted. By destroying the haulm the channel by which the disease is conveyed to the tubers is also removed, and as a consequence those unaffected will remain so. They will mature in the ground, or they may be lifted on the morning of a dry day and allowed to remain exposed till the evening, by which time their skins will be set. Any of the American varieties, also the Dalmahoy, Schoolmasters, Shaws, Dons, and other quick-growing varieties, and even the Magnum Bonum, may now in many districts be lifted, but the Scotch Champion and similarly late-maturing varieties must not yet be touched. The Potatoes have caused the winter greens and Broccoli where planted between the rows to be much drawn. When lifting the Potatoes in this instance first clear off the haulm, then fork out straight ahead, throwing the tubers behind, and working the soil up to the rows of plants on both sides.

Successional Crops.—The ground previously occupied by Potatoes if forked over as the process of lifting proceeds, cleared of all rubbish and levelled with a rake, will be ready for a sowing of Turnips; or

providing it was well manured in the first instance, it may be planted with breadths of Savoy, white Broccoli, sprouting Broccoli, Kale, Brussels Sprouts, Coleworts, Endive, and other quick-growing crops. The drills for the Turnips may on good ground be 15 inches apart, and suitable varieties are Snowball, Veitch's Red Globe, or the American Red Stone and Chirk Castle Black Stone. A distance of 15 inches each way will also suit the Coleworts and the small Savoy. Although it is late for planting Brussels Sprouts they may during a mild winter prove remunerative. These, and also Broccoli, greens, and the Drumhead Savoy, may be planted in drills 2 feet apart, and the plants 18 inches asunder in the rows, as in most localities they will not grow to a great size. The small varieties of Endive, such as the Moss-curl, may be planted about 9 inches apart each way, and the larger, of which the best is the Improved Batavian, about 12 inches apart each way. It is not too late to sow the former and also some of the Cabbage varieties of Lettuce, and any seed there may be left of the summer Cos varieties. The latter should not be thinned very freely; they will then form hearts quickly, and be found useful with Endive in salads. Parsley if sown now may perhaps be found useful during the winter and spring, and if some of the spring-sown be transplanted it will be improved, and is less liable to run to seed early the following spring.

The drills, for whatever purpose drawn, should be thoroughly soaked with water if at all dry some hours previous to planting or sowing. The Broccoli and greens ought to be planted very firmly, as they then take more readily to the soil. Water them in, and when found to be established draw the soil up to the stems.

Strawberries.—The present is a good time to form a fresh plantation of these, and if strong well-rooted plants are properly planted on good soil they will yield a crop of excellent fruit next season. The earliest runners are usually layered during July into 3-inch pots, but this season being rather showery plenty of well-rooted plants may be taken up with a trowel from between the lines of old plants. It is a mistake to cling to any old and perhaps worthless variety, Trollope's Victoria for instance, or to any other presumably good variety, should that not do well, especially seeing how cheaply plants of any good variety can be purchased. Keens' Seedling is a good old early variety, but Vicomtesse Hericart de Thury is a much heavier cropper. Sir J. Paxton is a good second early variety, but does not succeed on all soils, and both The President and Sir C. Napier are more to be relied on for yielding heavy crops of fruit of the best quality. Good profitable late varieties are Dr. Hogg and British Queen, the former sometimes succeeding where the latter fails, and *vice versa*. Ground that has either been trenched or deeply dug and cropped with early Potatoes will be found suitable for Strawberries, and after being prepared as above advised for the vegetables, should, previous to planting, be heavily trampled. Draw shallow drills 30 inches apart, and on rich soil 3 feet apart, and place the plants 18 or 20 inches asunder. Plant very slightly below the level, and make the soil about them as firm as possible. Those plants received by post or otherwise that have no soil attached to their roots should first be immersed in water for a few hours, and when planted the roots should be spread evenly in the soil. The best crops are usually obtained in the open ground, but in many small gardens they are substituted for Box on each side of the walks, and are certainly very profitable edging plants. Any established plants that have not borne more than two or three good crops, and which it is thought advisable to save, should have all the runners and a few of the outer leaves trimmed off; the beds hoed to destroy the weeds, and these and the loosest of the mulching cleared off. Cut off the exhausted plants with a spade, hoe the bed, and rake off loose rubbish. Do not dig the ground, but at once draw drills between the old lines, and plant out Broccoli or Savoy. Broccoli thus treated make very sturdy growth, and are less liable to be destroyed by frost. Any of the varieties above recommended are suitable for culture in pots. Those who intend growing a few are referred to the remarks on the subject on page 64 of this series.

Cabbage seed should now be sown in order to obtain strong plants to stand the winter. Suitable varieties are Heartwell Marrow, Enfield Market, Suttons' Imperial, and Early Rainham. Sow thinly, and protect from birds.

TRADE CATALOGUE RECEIVED.

Jules de Cock, Faubourg St. Liévin, Ghent.—*General Catalogue of Plants.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Culture of Double Pyrethrums (*C. L.*).—Full particulars of the treatment double Pyrethrums require appeared in No. 1003 of this Journal, to which we cannot do better than refer you.

William Tillery Melon (*A Young Gardener*).—The following is the description of this Melon, which was certificated by the Royal Horticultural Society in 1879—Fruit large and handsome, having a dark green skin, and regularly netted. Rind very thin. Flesh pale green, juicy, sweet, and of excellent quality.

Early Rose Potatoes (*A Young Gardener*).—Your crop of 683 lbs. from 19 lbs. of seed, occupying ground 36 yards long by 6 yards wide, is not exceptional. The crop from 33 yards by 13 yards of ground is much better; 61 lbs. of seed yielding 1794 lbs. is at the rate of a little over 8½ tons per acre. The results are satisfactory, but they have been more than doubled.

Grapes Shanking (*Subscriber*).—We are glad to hear that our advice has proved so serviceable to you. Shanking is generally caused by overcropping or defective root-action, the latter arising from stagnant soil causing the roots to decay, or a very dry border causing them to shrivel. The berries always stop swelling for a week during the stoning period. Your Vines are probably rather overcropped.

Beetles Infesting Parsnips (*J. E.*).—The insects sent belong to the genus *Hister*, one of the group of beetles called "Mimic," from the readiness with which they feign death. Hence they may be easily shaken off the plants on which they are feeding and then destroyed. But their usual food is animal and vegetable substances in a state of decay, and probably their attacking the leaves of Parsnips and Potatoes indicates an unhealthiness in the plants from some cause.

Chrysanthemum frutescens (*Subscriber*).—The plants intended for winter flowering should have the flower buds removed until within a month of the time that flowers are wanted. Cuttings inserted now will form small plants that will flower freely during the winter, five or six being grown in a 5-inch pot. Cuttings for producing plants for bedding-out next year may be inserted in September in sandy soil, the pots to be placed in a frame or propagating house, and shaded and kept close for a few days just to prevent flagging, then inured to light and air.

Heating Stove and Fernery (*H. R.*).—You will require four rows of 3-inch pipes to heat the stove, two along each side, or, if the house is a lean-to, at the front or in the pathway, and for bottom heat two rows of 3-inch pipes will be sufficient for a bed 3 feet wide. They should be surrounded and covered to a depth of about 3 inches with rubble, and over this place the plunging material. The same number of pipes as for the stove will be required for the fernery if to be kept at stove temperature, or two rows—*i.e.*, a flow and return, if for greenhouse Ferns.

Culture of Gold and Silver Ferns (*N. B.*).—The genus *Gymnogramma*, which you designate by the above popular name, includes many beautiful forms, all of which are of easy culture, and are from their distinct appearance especially deserving of attention. The compost they require is a mixture of fibrous peat and silver sand, the pots being of moderate size and carefully drained. A light position should be selected for the plants in a stove fernery, or a slightly shaded place in an ordinary stove would suit them; but in either case care must be exercised to avoid wetting the fronds when syringing, or the delicate "farina" will be washed off. Abundance of water is required at the roots, and if the plants are allowed to suffer in the slightest degree from inattention to this bad results invariably follow.

Culture of Euphorbia splendens (*A Young Gardener*).—The plant of which you sent a specimen is *Euphorbia splendens*. It is of easy culture, requiring a stove temperature, and a soil of fibrous loam and sand, with a small proportion of lime rubbish. The pots should be well drained, as any stagnant moisture is especially injurious to the plants, as their stems are very succulent. When the plants are growing freely water may be liberally supplied, liquid manure being also beneficial occasionally. Although succeeding well in pots this *Euphorbia* is more useful if planted out in a border against a wall in the stove, where flowers will be freely produced, showing a considerable portion of the year.

Culture of Vincas (*Ibid*).—*Vinca rosea* and *V. alba*, to which you refer, are useful quick-growing stove plants that require no special treatment, and flower freely. A rich light compost of loam, sand, and a small proportion of well-decayed manure suit them admirably. Abundance of water is required whilst the plants are growing. To form bushy specimens it will be necessary to pinch the shoots back and shift the plants as they fill their pots with roots.

Characteristics of a Good Pansy (*F. G. S.*).—In reply to your question we append from our Manual, "Florists' Flowers," the following description of the chief qualities a Pansy should possess to be fit for exhibition:—"1, Each

bloom should be nearly perfectly circular, flat, and very smooth at the edge; every notch or unevenness being a blemish. 2, The petals should be thick and of a rich velvety texture. 3, Whatever may be the colours, the principal or ground colour of the three lower petals should be alike; whether it be white, yellow, straw colour, plain, fringed, or blotched, there should not in these three petals be a shade difference in the principal colour; and the white, yellow, or straw colour should be pure. 4, Whatever may be the character of the marks or darker pencillings on the ground colour, they should be bright, dense, distinct, and retain their character without running or flushing—that is, mixing with the ground colour. 5, The two upper petals should be perfectly uniform, whether dark or light, or fringed or blotched. The two petals immediately under them should be alike; and the lower petal, as before observed, must have the same ground colour and character as the two above it; and the pencilling or marking of the eye in the three lower petals must not break through to the edges. 6, If flowers are equal in other respects, the larger, if not the coarser, is the better; but no flower should be shown that is under $1\frac{1}{2}$ inch across. 7, Ragged or notched edges, crumpled petals, indentures on the petal, indistinct markings or pencillings, and flushed or run colours, are great blemishes; but if a bloom has one ground colour to the lower petal and another colour to the side ones, or if it has two shades of ground colour at all, it is not a show flower. The yellow within the eye is not considered ground colour."

The Lady Apple (*R. P., Devon*).—The Apple to which you refer is the Api of pomologists, and the following description and history from the "Fruit Manual" may be of interest to you:—"A beautiful little dessert Apple; in use from October to April. It should be eaten with the skin on, as it is there that the perfume is contained. The skin is very sensitive of shade, and any device may be formed upon it, by causing pieces of paper, in the form of the design required, to adhere on the side exposed to the sun, before it has attained its deep red colour. The tree is of a pyramidal habit of growth, healthy, and an abundant bearer. It succeeds well in almost any situation provided the soil is rich, loamy, and not too light or dry, and may be grown with equal success either on the Doucin or Crab stock. When worked on the French Paradise it is well adapted for pot culture. The fruit is firmly attached to the spurs, and forcibly resists the effects of high winds. According to Merlet, the Api was first discovered as a wildling in the Forest of Api, in Brittany. It has been asserted that this Apple was brought from Peloponessus to Rome by Appius Claudius. Whether this be true or not there can be no doubt it is of great antiquity, as all the oldest authors regard it as the production of an age prior to their own. Although mentioned by most of the early continental writers, the Api does not appear to have been known in this country till towards the end of the seventeenth century. It is first mentioned by Worlidge, who calls it 'Pomme Appee, a curious Apple, lately propagated; the fruit is small and pleasant, which the Madams of France carry in their pockets, by reason they yield no unpleasant scent.' Lister, in his 'Journey to Paris, 1698,' speaking of this as being one of the Apples served up in the dessert, says, 'Also the Pome d'Apis, which is served here more for show than for use; being a small flat Apple, very beautiful, and very red on one side, and pale or white on the other, and may serve the ladies at their toilets as a pattern to paint by.' De Quintinyc calls it 'Une Pomme des damoiselles et de bonne compagnie.' Under the name of Lady Apple large quantities of the Api are annually imported to this country from the United States, where it is grown to a great extent, and produces a considerable return to the growers, as it always commands the highest price of any other fancy Apple in the market. In the winter months they may be seen encircled with various coloured tissue papers adorning the windows of the fruiterers in Covent Garden Market."

Names of Fruit (*W. H. Deane*).—The Grape is White Frontignan.

Names of Plants (*J. Williams*).—The plant with large red bracts is *Lycasteria formosa*; the other is *Bocconia frutescens*. (*Inrift*).—The specimen was very much crushed, but appears to be *Malva moschata*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE ADVANTAGES OF AUTUMN CULTIVATION.

(Continued from page 104.)

THE next point to be considered is the autumn cultivation of Potatoes, and in this case it will be the same as before stated for Lent corn, roots, &c., if the land is foul; if, however, it is comparatively clean our practice has been for many years to plough the land directly after harvest. As soon as the lumps of grass commence growing, and can be readily seen, these are forked out and carried away; the land will then be allowed to remain undisturbed until planting time. If, however, a few bunches of grass should appear they may be forked-out before proceeding to harrow or prepare the land for planting. Having completed our remarks as far as the surface cultivation is concerned we must now refer to the ploughing, which should be done by a heavy furrow, making the necessary distinction in the treatment of light or heavy soils. In various northern or north midland counties it is customary to drill or hand-dibble the root seeds on the stretch at 27 inches apart, in which case we advise that the land should be laid into stretches to lie for the winter months, in

order that in the spring they may be reversed, and that the dung may be laid into the furrows before reversing, in readiness for drilling the seed; this refers to the light and dry loams. Upon the heavy soils intended for Mangolds or Swedes the land may require to be worked down and the stretches reversed, and then lay out the dung, to be buried by the last reversal of stretches, and by this means the land will be brought into a light loose state, so desirable for root cultivation. It will, even on heavy land, not always be necessary to reverse the stretches the second time in the spring if the land is placed in stretches by steam power, as advocated by Mr. Smith of Woolston, whose system of management of heavy land is deserving of the home farmer's attention. By driving the tackle through the soil and leaving it on the surface like rubbly coal or limestone, after having been exposed to the alternations of winter weather, the dung may be laid out between the stretches or artificial manure strewn over. The land will then, after reversing the stretches and having laid hollow and dry during the winter, be found in a fitting state to work fine enough to receive the seed in the best condition.

We will next consider the best method of treating the land during winter when intended to be cropped in the spring with Lent corn or pulse. Again we shall have to recommend some difference in ploughing light and heavy soils. We will consider the light soils first, because these will generally be cropped with Barley or Peas. If for the former crop the land may be deeply ploughed and allowed to remain undisturbed during the winter months until the seed time. If the winter has been wet and the land lies close and cold it is often necessary to employ Coleman's scarifier, followed by the harrows and roller until the finest possible tilth can be obtained. If the winter has been dry and frosty, dragging, harrowing, rolling, &c., will be sufficient to produce a good tilth adapted for the successful cultivation of Barley. Bear in mind, however, that as no time can be stated for commencing to work the land it should not be undertaken until the land is white and dry upon the surface, after which the sooner the seed is drilled the better. We deprecate entirely any spring ploughing, as being not only an unnecessary delay of the seed time, but in dry harsh weather it has often resulted in the seed not vegetating with regularity. For Peas, however, we recommend the reverse, and the early sorts cannot be drilled too soon, for on the first suitable date the land must be ploughed and drilled, in order that rain or night frosts may not intervene; and it is also necessary because Peas, Vetches, &c., always succeed best upon a fresh furrow.

Heavy land usually cropped with Oats or Beans should be ploughed with a deep furrow to lie during the winter in ridges of such size as is usual in the district, and the land being properly water-furrowed and well cleaned, so that it may lie high and dry during winter, in order that the land in the spring may be planted with Beans as early as possible. If allowed to lie on the bare furrow during the whole winter the land can be worked early in the spring, and the seed should be drilled at once, for the early sown are the likeliest to escape the black aphides. Sometimes we have known the seed hand-planted in every other furrow, and the land ploughed with a shallow furrow just sufficient to bury the Beans. This plan is only advisable when the soil is very stiff and difficult to work, for we have seen the Beans germinate well, and frequently succeed much better than by drilling or hand-dibbling. The same method is recommended for the Oat crop, but we do not advise sowing Oats too early upon heavy cold land, preferring to wait until the land is white on the surface, and then drill after working the land sufficiently to obtain a fine tilth.

We may now refer to the autumn tillage of Clover or Saintfoin leas, for in these much Couch and Lop Grass is often found, particularly upon those fields when previously under a fallow; and with an adverse season like 1789, when it was quite im-

possible to clean any land during the whole year. If the lea grounds are intended for Wheat the same season it is especially desirable not to move the land deeply, because it would be too light, therefore in disposing of the couch before ploughing the surface of the soil only should be moved by the strongest scarifier. There should be some difference in the treatment of a Saintfoin lea compared with a Clover lea, for there is probably no better or cheaper way of preparing the Saintfoin lea for the next crop than by paring and burning. If Clover lea was burnt the value of the Clover roots would be lost, therefore the less labour that is bestowed on removing the couch before laying out the dung the better.

In reference to the comparative advantages of autumn cultivation in contrast with spring tillage there is first of all a much greater certainty of a given number of days being secured for tillage in the autumn than in the spring, because as soon as open weather commences the seed time has arrived. To this point we call the attention of the home farmer particularly, as it is impossible to do in the spring that which can be easily done in the autumn, although there are some days in the most favourable autumns on which the land can be cleaned, yet the employment of steam power renders it possible to perform much work which cannot be accomplished by animals, in consequence of the limited time at our command. We shall not therefore attempt any comparison between the cost of steam power and that of horses, because the former is quite possible in ordinary seasons, whereas the latter is impossible without disturbing the whole work of Wheat sowing, green-crop seeding, &c. We here repeat our firm conviction that after autumn cultivation has been effected, or in fact under any circumstances, nothing proves so injurious to the root crops as various ploughings in the spring, the land not only losing moisture but firmness also, both of which are necessary to successful root culture.

WORK ON THE HOME FARM.

Horse Labour.—In some instances the sowing of Turnips will still be unfinished, but the sooner it is done now the better. Ploughing the land and planting Thousand-headed Kale or dwarf Savoy Cabbages will be advancing according to the requirements of the stock on the farm, as well as the production of vegetables to be sold as the food of the people. The dwarf Savoy Cabbages may be made a profitable crop upon farms near a town for sale in the early spring should it not be required as food for the stock on the farm. It will always be desirable in the future to grow such root and vegetable produce as may be consumed upon the farm or sold as food, a system upon which we acted on our farm thirty years ago, and can therefore recommend it with confidence to the home farmer. The value of vegetables, too, is much greater now than it was at the period named, for strictly speaking the supply of vegetables, fruit, &c., is not at all adequate to the requirements of the inhabitants in towns. In some districts the hay clearing in the low-lying or water meadows has not been finished, for considerable hindrance to the making, carting, and stacking has been experienced in most of the late districts up to the time we are writing, and it is to be feared that it may interfere with the harvesting of early crops, such as winter Oats, early white Oats, Rye, Peas, &c. In the early districts of the south and eastern counties of England the above-named crops will be cut, thus employing some of the horses with the reaping machines; and generally speaking it is severe work for the animals, especially as it is desirable to make long days. It is necessary to work the horses in relays, by working each pair not more than four or five hours in succession. The reaping and tying harvesters have now been greatly improved, and the result of the trials and contests under the auspices of the Royal Agricultural Society of England at Carlisle has established the practice of tying the sheaves with string or yarn instead of wire, which was previously considered necessary in binding and reaping machines.

Hand Labour.—When the weather is favourable not only the work connected with the cutting of the crops, such as Peas, second crops of Clover, &c., will be pressing, but the growth of all late-sown Turnips has been so very quick and luxuriant that the hoeing by hand or singling must be done, or the ultimate crop will be seriously injured. We recommend the plan which we have frequently adopted under similar circumstances—that is, by working the horse hoe across the lines with the shares placed for leaving the plants in bunches, which prevents the plants becoming stunted; singling may proceed by hand labour only by women if men are not available through the urgency of other work. Our adjustment of the shares or knives of the horse hoe is to retain the foremost or centre share in its usual position, and reverse the two side knives by turning them outwards with a space between them sufficient to leave the roots in bunches of the right dimensions. This is easily done in a season like the present, when the plants are thick in the rows. If it is intended to grow stubble Turnips arrangements must be made both for the manure to be drilled and the women appointed to remove the sheaves or pooks of corn or pulse, so that the ploughing and sowing daily between them may be done, and thus two-thirds of the land may be seeded before the corn is carried. The result of this plan we have proved for many

years is a double weight of roots as compared with any portion left unsown until after the crop is removed.

The home farmer, where he has the care of a breeding flock, must now turn his attention to the scouring of rams of good quality, and in accordance with the flock under his management. Whether the stock are Hampshire or West County Downs, or Cotswolds, Leicesters, or any other breed, it is essential to take the first opportunity and thereby secure the best animals which are necessary for propagating the breed he has in charge. If the stock required upon a home farm is for grazing or winter feeding for mutton, this is a good time for selecting animals best adapted for the purpose. The lambs may now be shorn and made out as fat tegs. The breeding ewes for making early lambs should be dipped, for in the enclosed districts they will be quickly struck by the fly, producing loss of wool. By this time also the rams will be running with the ewes, and care should be taken to have the rams ochred so that each ewe as served should be marked, and if necessary may be removed for inferior feeding if high feeding has been adopted for the purpose of early breeding. All the yearling off heifers in the pastures should run together, and have a well-bred young bull of the same age and of the required breed turned in with them, so that the calves may be expected to fall just when the earliest grass is at the best—during the early part of the month of May. We find the price of sheep is rather higher than last year at this time, and the sale for store cattle very dull, particularly for the general run of the Irish imported stock whether of steers or heifers. Dairy cows and early calving cattle are selling well, and are likely to pay well this year in the hands of home farmers who are competent managers of a herd of dairy cows.

BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION.

At the Council meeting of the Society held at the Grand Hotel, Bristol, on Tuesday last, the chair was taken, in the unavoidable absence of the President, by H. G. Moysey, Esq. There were also present Messrs. Jonathan Gray and J. C. Moore-Stevens (Vice-Presidents), C. T. D. Acland, J. D. Allen, E. Archer (Colonel), H. J. Badcock (Treasurer), J. C. Best (R. N.), C. Bush, R. H. Bush, V. P. Calmady, F. E. Drewe (Colonel), T. Dyke, Charles Edwards, Walter Farthing, A. Gibbs, F. Gill, J. E. Knollys, R. Lang, R. Marker, R. Neville, E. J. Sanders, Sir John Shelley, Bart., A. Stanford, and J. Goodwin (Secretary and Editor).

A letter was read from the Most Noble the Marquis of Abergavenny, thanking the Society for his election as President for the ensuing year, and expressing a hope that his year of office would be one of prosperity and success.

Mr. Charles Edwards, as Chairman of the Finance Committee, brought up the quarterly statement of accounts; and the cheques which had been drawn for the payment of prizes and other disbursements in connection with the recent meeting, were sanctioned by the Council. It was also reported that so far as it was at present possible to make an approximate estimate, the probable loss on the year's proceedings would amount to £1000.

Mr. Charles Edwards, in the absence of the Chairman of the Stock Prize Sheet Committee, asked for the amount of £2070 for stock prizes at the Tunbridge Wells meeting, which was granted by the Council.

The sum of £200 was granted for poultry prizes at Tunbridge Wells, Mr. G. Herbert Morrell repeating his offer of £6 6s. for prizes for Langshans.

The amounts voted for the several departments of art, music, and horticulture at Tunbridge Wells were the same as at the last meeting of the Society.

The Stewards and Officers for the Tunbridge Wells meeting were appointed, subject to their written consent to act.

Mr. Knollys reported that he in company with Mr. Jonathan Grey had inspected the ground offered by the Local Committee at Tunbridge Wells for the trials of implements. The Committee had afforded every facility, and had been most willing to comply with the requirements of the Society; and, subject to certain arrangements which had been easily made, the Stewards had no hesitation in approving the ground offered as admirably suited for its purpose. The Secretary also announced the payment by the Local Committee of the £800 due from them in accordance with the regulations; and the Council resolved that a special letter of thanks be written to the Local Committee for their promptitude and courtesy in carrying out the suggestions and requirements of the Society.

A communication from Mr. W. Stanford of Steyning, suggesting that a class for yearling agricultural colts should be added to the stock prize list, similar to that for yearling fillies, was referred to the Stock Prize List Committee.

A letter from Captain Sherston, suggesting plans for the improvement of the show of horses at the Society's meetings, was also referred to the same Committee.

TOY PIGEONS—THE ARCHANGEL.

THIS is a peculiar and gorgeous breed. It is not an old one, or at any rate has not been very long known to English Pigeon fanciers. The first mention of it which we have seen is in the "Dovecote and Aviary," published about thirty years ago. The

description there given can hardly be improved upon. "The colouring of these birds is both rich and unique. The head, neck, and fore part of the back and body is chestnut or copper colour, with changeable hues in different lights. The tail, wings, and hinder parts of the body are of a sort of blue-black; but many of the feathers on the back and shoulders are metallic and iridescent, a peculiarity not usual in other domestic Pigeons. The chestnut and blue-black portions of the bird do not terminate abruptly, but are gently shaded into each other. There is a darker bar at the end of the tail. The iris is very bright orange red; the feet clean and unfeathered and bright red. Archangel Pigeons have a turn of feathers at the back of the head, very similar to that of the Trumpeter, or to Aldronandi's woodcuts of his *Columba Cypria*. It is the colouring rather than the form which so specially distinguishes them. Their size is very much that of the Rock Dove." The author states that the variety was, when he wrote, rare, and that it existed in the then famous Knowsley aviaries, from which he had a pair; we, too, in childhood had a pair descended from the same stock. It is true that "distance lends enchantment to the view," and that youth clothes all that pleases it in the most glowing colours; still, making allowances for this exaggeration, we feel sure that these birds were of surpassing brilliance, and such as are seldom, if ever, now seen. The coloured part of their plumage was the most brilliant copper colour, not purple nor sandy, and the black was really and intensely black. They were plain-headed—i.e., without peaks, and we well remember being shown by the donor of them a point-headed bird as something abnormal. Our pair turned out two cocks, and the strain came to an end. Their beauty, however, lingered in our recollection, and years afterwards we saw a pair advertised by a then successful exhibitor; we bought them, but great was our disappointment at the arrival of a pair of comparatively speaking dingy creatures. They, too, turned out cocks, and it seems a peculiarity of the breed that two cocks are very frequently reared from one nest, and that it is extremely difficult ever to obtain a really good hen.

Archangels are hardy and prolific. One of their great charms is their elegance and activity on the wing. Since these former failures we have procured and bred many of various types and excellence, and have found them invariably good breeders and parents. We delight in watching them ever flitting from gable to gable, bowing and playing in the sun, and then swooping down to their house again. Archangels are no longer a rare variety, but the many are mediocre and very few good. The difficulty of procuring and breeding them good seems to be caused by this:—There are several sub-varieties varying in colour; these have been much crossed, hence we never know the exact result which a union will produce. The chief points of excellence are that the copper colour should be as bright as possible, and the black really black; this latter is very difficult to attain, we might almost say impossible. Poor birds are a dingy blue, or blue and copper, when they should be nearly black; such birds should be killed, but not hastily, for all Archangels are very dingy during their first six months, and cannot be called brilliant till they are fully a year old. An experienced eye can, however, soon detect on the neck and back signs of brilliance to come. In some strains the copper-coloured part is more purple, and in such the back is very brilliant like the breast of other Pigeons, but the black portions are apt to be dull, and the colour, too, of the heads dull, which is a great fault. Others, again, have quite yellow heads and breasts, and these if glistening and not sandy are valuable for breeding. When mated with a rich purple bird they often produce birds of the very brightest sheen and colour. To our taste a copper colour inclining to purple is the most perfect type; when this extends evenly all over the head and quite down to the thighs, and when the black parts of the body are really nearly black, the bird is of great value and extreme beauty. A flight of such is not to be forgotten. In one point we slightly differ from Mr. Dixon, the author of "The Dovecote and Aviary." He says that the black and copper should shade gently into each other. In all the best Archangels we have ever seen they have been well defined. We have had good Archangels with pearl eyes, but quite agree with the above description, that their eyes should be bright red, which seems to agree best with their general colouring. Their feet are of a brighter red than those of any other Pigeon we know. A peak to the head is now almost *de rigueur* in the show pen. Whence the derivation of their strange name? We have been asked this dozens of times. We well remember the horror of a visitor once staying with us when a servant quietly announced, "The cat has run off with an Archangel this morning!"

We formerly thought that they had probably been first brought to these shores by an Archangel merchant or ship. A correspondent ingeniously suggested some time ago that their name

had perhaps been given to them from the similarity of their colour to that of various great Italian pictures of the Archangel Michael. There is much plausibility in this suggestion. Breeds of similar colouring certainly exist in the aviaries of some of the great oriental Pigeon-fancying potentates. When introduced to Europe they would very likely have first come to Italy. In Transylvania and the Tyrol they are still common.

The nomenclature is, however, only of secondary interest; it is undoubtedly a most beautiful breed, and one which we can recommend to young fanciers almost more confidently than any other. Archangels give no trouble, they invariably make good nests, and do not leave their eggs to tumble about on the boards or on the ground as some Pigeons do; we have never, too, known them to forsake their young ones. We should add that self-coloured Archangels, specially blacks, are sometimes shown. We have ourselves this year bred a purely yellow bird—i.e., yellow all over without a dark feather, from a dark pair inbred. We do not, however, admire any of these birds, and consider the two rich colours the chief beauty and characteristic of the breed.—C.

VARIETIES.

THE PEACH BLOW POTATO.—The American correspondent of the *Irish Farmers' Gazette* writes as follows:—Our best standard Potato at present is the Peach Blow—a fine, large, smooth, sound Potato. I have raised them for years. A new variety came to the front lately, and were very highly spoken of—the white Peach Blow. They were as fine Potatoes as I ever eat—as dry as the original Peach Blow, more uniform in size; but their white smooth skin gave them a higher stand in the market, and they were eagerly sought after by the shippers. I bought some and determined to try a crop of them. I planted an acre of them under very favourable circumstances; alongside were dropped a couple of rows of the red Peach Blow. When they came up over two-thirds of the seed of the white Peach Blow were a failure, whereas every set of the red Peach Blow produced a vigorous plant. Now, it must be borne in mind that the flesh of the red Peach Blow is as white and floury as the white; indeed, they resemble a good deal the old favourite kind the Apple as much as any Potato I can think of. We have a vast variety of Potatoes grown here, but the favourites are the Peach Blow, Snowflake, Early Vermont, Early Rose, Champions, &c. Each of these varieties varies considerably in the localities and different soils in which they are planted. I suggest to Irish farmers that they send over here and have a few barrels of our Potatoes selected and sent over to be tested as to their quality, and if considered favourably any amount of seed could be procured from the St. Louis market. The price of Potatoes here last fall ranged from 30 to 40 cents per bushel, or about 4d. to 6d. per stone; this spring and summer they could have been sold from 3d. to 4d. per stone (market down). A change of seed like this I believe would lead to the best results.

— **AYLESBURY DUCKS.**—They are reared annually in enormous quantities in and around the town of Aylesbury, and it is not uncommon to see a ton weight of ducklings of six to eight weeks old sent in one evening to London by rail from the town and neighbouring villages. The trade for them commences in February and lasts till about the end of July, and during all that time it is difficult to keep up the supplies to meet the great demand. The birds are generally killed when six weeks old, at which time they weigh about 3 lbs. each, and they realise prices ranging from 9s. to 21s. a couple as the season advances. After Ascot summer meeting it is always noticed that the prices rapidly fall. The bulk of the rearing is done by cottagers, who make a good living by the process, and many save considerable sums of money. It will surprise many, perhaps, to hear that upwards of £20,000 a year is returned to this immediate neighbourhood for Aylesbury Ducks alone. It is a curious sight to see the cottages of the "duckers," as the breeders of them are called, during the spring, when they have the youngsters in every room in their house, from the kitchen to the bedroom, and their clamour when feeding-time approaches is terrible. The birds intended for market are never allowed to go into water, and often are not even permitted to go out of the purlieus of the dwelling-house till they are killed. Their food is at first eggs, boiled hard and chopped fine, mixed well with boiled rice, and this is given

to them several times during the day. As they grow, and are capable of consuming more, they are fed upon barleymeal and tallow greaves, mixed together with the water in which the greaves are boiled.—(*Cassell's Illustrated Book of Poultry.*)

— THE PRACTICAL TREATMENT OF SEWAGE.—A correspondent informs us that “last week a party of 140 gentlemen visited the sewage works of the Native Guano Company at Aylesbury. A series of demonstrations were given, showing the practical working of the A B C system, with which considerable satisfaction was expressed.”

— HOP INTELLIGENCE.—The plantations are making fair progress, and good-sized Hops may be seen in the earlier descriptions. The later sorts have thrown out strong laterals, which are fast breaking into burr, and the progress of the mould has been to a great extent checked, although in some few grounds it is making sad havoc. The foliage is clean and of good colour. Altogether prospects augur a somewhat large yield, while the quality can scarcely fail to be superior if the weather continues favourable.

— AGRICULTURAL PROSPECTS.—The *Mark Lane Express* of August the 2nd states:—“Prospects this week are decidedly gloomy throughout the country. The continued rains and heavy storms have laid the grain crops, where they are at all thick, on the ground, and the Barleys especially have been greatly injured. As might have been expected from the excess of moisture at this time of year there are now complaints on every hand of mildew, and a ‘blighted appearance’ is very noticeable in many districts. Harvest, which would have commenced during the first week in August, has been retarded by the weather, and the absence of bright sunshine is now working great mischief amongst the grain crops. Some Oats have been cut, but the crop is not well spoken of. Some Peas have also been cut, and, together with the Bean crop, they are as a rule reported favourably. Root crops are making a rapid growth of leaves, but fine weather is needed to enable them to form good bulbs; and the constant rains have given the weeds an insurmountable advantage over the hoe. The hay crop has been irretrievably ruined; one-third spoiled in the field, one-third spoiled in the stack, and the remaining third spoiled before it is cut, as put by one of our correspondents, is, we fear, but too true a statement of actual facts. A large acreage of meadow grass now lies on the ground unfit for anything but litter. From Herefordshire we have accounts of liver fluke amongst sheep to a very serious extent; in other respects stock are reported as healthy, and doing well on abundance of keep.”

— SALE OF SHROPSHIRE SHEEP.—Mr. T. J. Mansell's annual sale and letting will take place at Dudmaston Lodge, Bridgnorth, Salop, on Monday next, August 9th, when twenty-three shearling rams, forty-five shearling ewes, and thirty stock ewes will be offered at public auction by Messrs. Lythall & Mansell. The shearling rams and ewes are principally got by County Member (winner of first prize at the Exeter meeting of the Bath and West of England Show; first prize at the Shropshire and West Midland Show, 1879, and champion prize for the best ram in the yard; first prize at the Worcester meeting of the Bath and West of England Society; and first prize at the Shropshire and West Midland Show, 1880) and Pride of Montford, a ram bred by Mr. Minton, by Calcot, and the sire of Dudmaston Hero (winner of first prize at the Worcester meeting of the Bath and West of England Society; first prize at the Shropshire and West Midland Show; and champion prize for the best ram in the yard).

PURELY MATED QUEENS.

SINCE the introduction of Italian bees much effort has been put forth in the endeavour to have the young Italian queens mated with pure Italian drones, resort being had to attempts at fertilisation in confinement, isolating the queen, rearing stocks on islands and other out-of-the-way places, and a common plan being to dispose of as many of the black queens and drones in the vicinity as possible. Much money and labour have been expended in these directions with not always satisfactory results, and it is out of the reach of a large majority of bee-keepers to obtain purely mated queens in these ways; hence they have to run their chances by raising as many pure drones as they can in their own yard. This will go a great way towards the desired object, but we can

still add much more that is within the reach of all bee-keepers. But we will begin back at the start and see how best to accomplish this. The time taken to raise a queen from the egg to hatching is sixteen days, but they are many times raised from eggs already hatched as workers before the bees take them to raise queens of; hence some queens are hatched in eleven or twelve days. These young queens usually do not make their fertilising flight under five days old, and we should have had plenty of drones flying from our best Italian stocks by the time these young queens are ready for their bridal trip. Drones and young queens usually fly from one to three o'clock in the afternoon. Now we want to get the start of these black and hybrid drones if we can, so about half-past ten or eleven o'clock in the forenoon we will go to our stocks containing young queens of the right age, and also to our pure Italian stocks from whose drones we wish to breed, take off the caps of the hives, then the quilt or honey board, and thoroughly sprinkle each stock with very thin warm honey, or a like mixture of sugar syrup, and close the hives at once. In a very few minutes the air will be filled with bees, drones, and young queens (if of the right age) rushing out of the hives like a pack of schoolboys at recess, and making about as much noise too, the worker bees to hunt around for that inflow of warm honey, thinking perhaps that the flowers have got tired waiting for the tardy bees, and are bringing it to the hives, roots, plants, honey and all; the drones and young queens hearing the noise want to know what it is all about, and come out to have a “finger in the pie” too; and as there are but few drones flying at this part of the day your chances for purely mated queens are tenfold greater, and too, with drones raised from the most prolific queen, whose bees are the hardest workers. This plan followed up day after day till all the young queens are mated will well repay all extra trouble in bringing it about.—WM. M. KELLOGG (in *The Prairie Farmer*).

THE BRITISH BEE-KEEPERS' ASSOCIATION.

FIRST NOTICE.

IN now giving an analysis of the Exhibition of this Association our object will mainly be to direct attention to those novelties which in our opinion may be hoped to hereafter contribute to the comfort of the bee-keeper and the productiveness of the bee. The schedule was divided into thirty-six classes, and drew together 220 entries; but this number hardly represents the total, since in hives the Committee had stipulated that duplicates were to be shown prepared as for summer and winter. The show of honey, as we remarked last week, was of wonderful quality, and the whole Exhibition a decided success.

Class 1, stocked frame hives, two exhibits, neither possessing anything very noteworthy. No. 1 had in front a moveable grating for preventing the blue tit from feeding on bees in winter. This is of course old. The surplus boxes were placed around the stock. The next three classes contained good Ligurian, Carniolian, Cyprian, and Holy Land bees. The two latter attracted most attention, because of them we know the least, and many will say of the last “the less the better” when they know their tempers. Class 5, observatory hives, two entries. Mr. Abbott (silver medal) showed a considerable improvement upon his observatory of last year, which was then crude and unsatisfactory. The hive consists of an oblong box of plate glass, the length of which is considerably greater than the contained frames require. The roof of glass does not rest on the sides, but between the two; there is an eighth of an inch space through which the frame ears, made of tin plate, pass. Handling these we can slip the frames backwards and forwards the extra length of the hives. Such was the arrangement last year, but we have now an addition which makes a new thing of it. The glass roof, instead of being in one, consists of strips running the way of the frames, and between these strips we have again one-eighth of an inch space. On the top of the frames are three eyes placed in line near its centre, and a tool is provided not unlike a bradawl, the blade of which has been bent to a right angle near its middle. The frame to be examined is pushed until it stands immediately beneath a roof slit; the tool is now passed through the eyes, and becomes a pivot on which the frame can be revolved, and when parallel with the hive side it can, by drawing the tool along the slit, be placed against the glass and inspected. It does not appear to us that plate glass is essential on more than one side, wood replacing the rest, and so reducing cost. Mr. Scott (bronze medal) staged a hive consisting of frames and bees in separate cases with glass sides, sliding in close contact on a lidless box. The separate cases have no bottoms and do not touch the floor, so that bees can pass from one to the other while heat is economised. Class 6, best hives.—Messrs. Neighbour were placed first with a hive having a straw crown board in three pieces, while its principal feature is a plan for preventing or passing round frame ends during winter. The frames must be removed, and afterwards placed across the hive for the purpose. Second was Mr. Abbott with a section crate as an overhead traveller, a plan which would, we think, hardly work. Third Mr. Holland. The section crate has permanent separators—a considerable defect, as

comb once attached to them would always after cause trouble. The side dummies and chaff box are good. Mr. Clapp was commended for a very convenient hive, the frames and body proper of which are in all respects the Cheshire hive of 1874. It has a quilt, which is neatly held in position by hinged strips.

Class 7, hives for general use limited to 15s.—Mr. Green was first with a well arranged hive, which has two thin division boards standing against its sides when all the frames are in use. For wintering some of the frames are removed, when the division boards are drawn towards the cluster. Brads are fixed in the hive front and back, which project so little that they do not prevent the movement of the frames, but they act as stops for the division boards, between which and the hive sides chaff is placed. The door is neatly regulated and a porch provided. The crate box above becomes the chaff box for winter. Mr. Hooker took second honours with an excellent hive having month side and front, so that turning the hive a right angle will change from one mouth to the other according to season. The super case opens to the perpendicular, giving convenient staging whilst manipulating. Mr. Hooker showed this hive in the flat with all parts ready to nail up, and again in plank with every piece set out. No. 19.—Mr. Holland had a lid in central part of super case to admit of chaff filling for wintering. No. 18.—Mr. Abbott had a novel super case and is good for the money. In Class 8 the efforts of cottagers to construct hives from beef boxes, lobster boxes, &c., were conspicuous, and fully prove that fairly convenient and thoroughly useful frame hives may be made by those having a little mechanical tact for about 2s. 6d., or even less. The prizes for supers fell to Messrs. Green, Hooker, and Clapp. Mr. Green, instead of the usual wooden strip passing under the section box and resting on the hive frames, introduced one of tin, T-shaped, in sections, which is a quarter of an inch over the hive top. This saves both in propolis and in risk to bees, and is a decided advance. Mr. Green gave us thumb space between boxes, and here Mr. Hooker was before him. We think the best combination would be the wooden bearing for the separator, with wider tin plate beneath to give a resting-place for the boxes. In this we should have the advantage of the two. Mr. Green tightened up the crate with a lock spring.

Honey was nearly all of finest quality and appearance, and the Judges must often have been puzzled. Class 11.—Mr. Warren showed 147 boxes, and Mr. Thorne forty of magnificent stuff, while Rev. E. Bartrum came third with three beautiful Stewarts. No. 49 has been left too long on one hive, as the capping was unduly thickened. In Class 12, mixed supers, the straws were far behind the rest, a fact which speaks loudly against fixism. Mr. Thorn stood first, but we think he ought to have been disqualified for entering in the wrong class; Mr. Dunman third, and Rev. E. Bartrum fourth, we should have reversed. Class 13.—Rev. J. G. Jenkyns showed a beautiful super, 36 lbs. nett. Mr. Scott's glass was artistic. Classes 14 and 15.—Thirty exhibits, all excellent, Mr. Cowan sending 48 lb. sections in glazed packing cases, which only secured third place. Class 17, extracted honey, contained no sample that was unworthy of commendation. The conclusion of the analysis must stand till next issue.

OUR LETTER BOX.

White Grubs Carried out (*Amateur, Warrington*).—Remove your super at once or your bees will take the honey down into the hive. The carrying-out of immature bees is a proof that the storing of honey has ceased, and that the bees are anxious to get rid of the drone grubs that can never be of any future service to them.

Dwindling Stock of Bees (*A Yorkshire Bee-keeper*).—We fear something must have happened to the queen of the stock which you describe. This most likely occurred in the early spring, and the bees seem to have raised another queen who has not turned out well. As you and your friend could see nothing of her with all your careful searching it seems not improbable that the hive had only a fertile worker in place of a proper queen, especially as you mention drones among the few surviving bees. Starvation in the early spring may have had something to do with the failure. We have had a dwindling swarm this spring of which we almost despaired, but it took a sudden turn in May and has wonderfully recovered. Warm weather and abundant honey in the flowers were its only cure. We advise you a little later, if the comb is fresh and good, and you think it worth while, to add to it the population of two or more stocks rescued from the sulphur pit, and to feed them up well at the end of August and through September.

Removing Bees from a Tree (*John Holliday, Silloth*).—To remove the bees you must first get possession of the brood comb. You will commence operations by driving the bees from their combs by smoke, and as you get portions of these somewhat cleared you will cut them loose and remove them. The honeycombs should have the bees brushed carefully from them, when they may be placed one by one in a pail and covered with a cloth. The combs containing brood will be taken out as they can be reached and placed by themselves after all the comb have been taken; the bees will be found hiding probably in some unreachable recess, but we can yet get them by strategy. The brood combs had better now be skewered together with half an inch space between each on wooden skewers, when the whole will be lifted into the hollow in such a way that it may by-and-by be easily taken away bodily. The bees are now left for the night, or at least for two or three hours. They will as soon as all appears quiet return in company with the queen to their brood, in order to give attention if needed and keep it warm. The combs, queen, and bees in greater part can now at once be taken to the foot of the tree to be dealt with according to circumstances. The queen being present, before long almost all will join. If it is intended to place the dislodged stock into a frame hive the brood combs as taken may be transferred into frames at once if this would not make them too large to stand in the tree-hollow.

Colour Characteristics of Ligurian Queens (*S. Wigston*).—Ligurian queens differ much in appearance, and it is not uncommon to find sister queens

produced at the same time and in the same hive extremely unlike. No queen should be condemned until her progeny has been seen. Some, although quite dark themselves, produce beautiful workers. When first hatched they are generally much yellower than at a few days old; but after this, as the abdomen extends by an increased development of the ovaries, the previously concealed yellow portions of the abdominal rings are brought into view and the general appearance once more brightens in consequence. The queen to which you refer will no doubt from this cause improve both in size and colour. Pure Ligurian workers ought to have three yellow bands, and the brighter these are the more handsome would the bees be considered. If the workers should be found to vary considerably amongst themselves you may conclude that your queen is hybrid. Ligurian queens actively ovipositing are generally somewhat larger than black ones.

Metheglin (*Apiator Vetus*).—You do not say in your letter to whom you refer when you complain of the imperfection of the recipe, but generally it may be stated that the proportions of water and honey are immaterial. The more water and the less alcohol, the weaker the metheglin. The saccharine matter of the honey undergoes fermentation in the presence of the yeast, together with some nitrogenous substances contained in the mixture, and alcohol is the result. The case of ale and wine furnishes an illustration. Weak worts containing little sugar if fermented produce not more than 5 per cent. of alcohol, while sweet Grape juice will yield similarly 25 per cent.

REMARKS.

25th.—Fine bright warm day, cloudy evening.
26th.—Heavy rain during the night, close damp day with heavy showers, bright hot sun at intervals, heavy rain for short time 9 P.M.
27th.—Very fine day, hot sunshine, high wind, calm evening.
28th.—Warm dull morning, slight showers, very little sunshine, good deal of cloud.
29th.—Dull morning with heavy showers and high wind, bright sunshine in afternoon, very fine evening.
30th.—Dark rainy morning, showery during the day, sunshine at intervals, gusty wind, rain in evening.
31st.—Cool in morning but very fine and bright, cloudy in middle of day, clear evening.

A very wet week ending a wet month. June and July of 1880 have been even more rainy than June and July of 1879. The following are the figures:—

	1879	1880
June ..	4.76	4.04
July ..	4.17	5.10
Total in two months ..	8.93	9.14

—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 4.

GREEN Plums and Apples are now the main supply of our fruit market, the former showing signs of heavy crops. Grapes from the Channel Islands are now reaching us in large quantities, prices being low. Vegetables are plentiful, with but slight alteration.

NOTES ON STRAWBERRIES.

LITTLE labour has been needed this season for Strawberry runners after they were layered in pots ; the rain has been so abundant that scarcely any watering has been required, whether the runners were placed in small or large pots. The latter practice I more strongly advocate than ever, and I can produce better plants and more satisfactory results in every way than by the other system. Good fruits are produced under both plans ; yet where the layering into the fruiting pots is carried out no check is occasioned, and attention is only needed to develop good crowns and thoroughly ripen them. One of the strongest objections raised against this system by various cultivators who adopt the other is, that when the runners are layered into the large pots the roots go direct to the sides and leave the soil in the centre without roots. This is not the case. Before autumn the pots are full of roots.

The present is a good time to either layer runners for making new plantations, or potting the runners, placing them in a frame or under the shade of Peach trees in early houses. The latter plan is preferable, and in dry weather watering can be done more readily. It also allows cultivators the opportunity of clearing off the runners that are not required, thus giving the plants that have to produce a crop next year every chance to thoroughly ripen their crowns for the following season. When established in small pots the young plants can be placed out at once, the distance between the rows and plants depending on whether they are to remain for permanent fruit-bearing or for stock next season. Eighteen inches between the rows and 1 foot from plant to plant is ample for the latter purpose. Between the rows Lettuce and Endive can be planted. Young plants are preferable from which to obtain runners ; they are earlier and much more vigorous than from old stools, or from those that have been forced. Some contend that planting young plants purposely to obtain runners for forcing is a waste of ground and labour, but it is surprising what a number of runners a few vigorous young specimens will produce. First, a crop of Lettuce and Endive for winter is obtained ; secondly, an abundant supply of runners, which is necessary where the spring supply of Strawberries is an important matter ; and lastly, the plants can be cleared-off in time for a valuable crop of Coleworts or Little Pixie Cabbage. Forced plants are useful if planted out for affording a crop of fruit the following year, and they will give a better return than runners layered and planted, unless the layering is done early.

Strawberries do not succeed so well upon trenched ground as upon firm solid land, especially if much of the lower soil is brought to the surface. If the ground is trenched and a crop of Potatoes taken, the Strawberries being then planted appear to do much better. This will not apply to gardens where the soil is of a tenacious nature, but in light soils it is much better than newly trenched ground. Sir Charles Napier Strawberry will not thrive on light newly trenched ground, especially if the winters prove severe. In planting this variety a sheltered position should be selected, that is in northern counties, and some little protection afforded to the crowns in winter. It is valuable for forcing, and the fruit is adapted for travelling better than almost any variety. When grown in pots it must be sheltered in winter, or else it will be much injured and prove unsatisfactory for forcing. When cultivators have to deal with light soil it is wise to spread over the surface before winter a good coating of clay, so that the frost will thoroughly pulverise it, and it should then be regularly and evenly worked into the old soil. Clay incorporated with light soil for Strawberry-growing will be found far more beneficial than a thorough dressing of manure. Vicomtesse Héricart de Thury is a valuable variety for light soils, and evidently appears to fruit equally as well as if planted on ground more favourable for Strawberry culture. Under cultivation in pots it succeeds very well potted moderately firmly. It is very hardy, and is not injured in the least if left outside in pots and unprotected during winter. Sir Joseph Paxton, Eclipse, Underhill's Sir Harry, and British Queen have also been tested by leaving them out unprotected ; their roots have kept in good condition, and the plants have forced well. They have started into growth more freely than if kept in Peach houses, vineries, or frames, and frost excluded. British Queen is a most unsatisfactory variety with me on a light soil, and I have hitherto failed to grow it well in pots. When it is well known that severe weather will not injure the roots of Strawberry plants in pots it will be a great advantage to many gardeners to be able to leave them outside, so as to set their frames at liberty to be occupied with Lettuce and Endive where winter salads are required in quantity.—WM. BARDNEY.

CURRENT TOPICS.

THE POTATO DISEASE.—I do not think the remarks which have lately appeared on the disease of the Scotch Champion will have startled anyone who has grown this variety for several seasons and watched the course it was taking. Up to the season of 1878 it was free from disease with me and about here ; but last season, although not affected so much as many varieties, it was diseased to a certain extent, and this season it appears to be going as fast as most varieties. I have observed this to be the case with many new Potatoes. When they were introduced they were able to resist the disease, but this gradually gained on them until they had no claim to be regarded as disease-resisting, and this, I fear, is the case with the Champion. One would gladly believe that the remarks of "W. B. W." (page 110) about selecting the best tubers for seed is the surest way of keeping up the disease-resisting constitution of the Potato, but even this has failed with us. For two or three seasons I have selected the very largest tubers I could obtain for seed of International Kidney, Red Emperor, and others, some of the former being over three-quarters of a pound in weight when placed in the ground this spring, and more than

half of the produce from them is destroyed by the disease at the present time.

I cannot agree with the writer who follows "W. B. W.," and asserts that "about one-half the losses by the disease arises from want of knowledge and apathy on the part of the growers." What this want of knowledge in Potato growers may be it is hard to understand. I know many gardeners, farmers, and cottagers who in this and other seasons have given the best part of their knowledge and personal attention to the Potato crop, with the result that half the crop or more was lost. In my opinion the weather alone rules the state of the Potato crop. No disease was visible here until after some days of wet weather about the beginning of July, and since then it has rained almost daily, and what promised to be an extremely fine Potato crop has been utterly ruined.

SCALDED GRAPES.—The timely and thoroughly practical remarks at page 109 from Mr. W. Taylor can hardly be too often repeated or confirmed at this season, when neglectful ventilation may more than half destroy what might be fine winter crops of Grapes. I find that moisture condenses much more freely on Grapes in cool houses than where fire heat is employed, and if the ventilators are closed all night it is most difficult to prevent moisture collecting in the morning. Allowing the ventilators to remain open all night at the top of the house will not keep down moisture. Air must be admitted at the front also to keep up the circulation. This brings me to confirm what Mr. R. P. Brotherston says on this matter at page 118. To leave the ventilators open top and bottom at all times is the right way to secure well-finished Grapes. I never read any remarks on the management of Vines in which I could so thoroughly concur as those. Last year many doubts were expressed about the correctness of my ripening Grapes in summer without fire heat, the favourable climate here being the only excuse for it; but surely if the same thing can be accomplished in East Lothian it might succeed in many other parts. It is very satisfactory to see the way in which Grapes, especially Black Hamburgs, colour during July, August, and September in a house without fire heat. Let me therefore advise your readers who are interested in the matter to practically test Mr. Brotherston's system, and I am sure they will be more than satisfied with the result.

THE CELERY FLY.—No season passes without many complaints against this insect being made, and from experience I know it is troublesome enough; but with this, as with all other insects, the best way is to take it in time, as it is easier killing a dozen than destroying thousands. Salt is one of the best manures which can be applied to Celery at any time, and there is nothing better for killing the fly. When mixed with soot and sprinkled on the plants when the leaves are moist, on the first appearance of the fly, no further damage will be done.

SUCCESSIONAL CROPS.—At the present time, when many long rows of our midseason Peas are being cleared off the ground, we lose no time in hoeing and cleaning the ground, Turnips and Spinach being sown on the place at once. It is now too late to plant greens to come in well in either autumn or winter, but it is just the time for the above two crops, and they will be found most useful during the winter.—A KITCHEN GARDENER.

THE POLYANTHUS.

MUCH discussion has arisen whether the Polyanthus has been produced from the Cowslip, and from a careful examination I have no doubt it has. This spring I saw a large Cowslip in a cottage garden showing evident signs that it was struggling to emulate and take its place amongst the Polyanthus.

It is now seventy years since I commenced growing Polyanthus, and I remember a few I then cultivated which time has banished from our gardens. The earliest was a variety called Faulkner's Black Prince. It was particularly high in colour and nearly destitute of symmetry, and no doubt was cherished on account of its colours. It was used as a show variety for a few years. A passing notice of Faulkner as a florist will not be out of place. He commenced growing flowers before the year 1800, and I knew him personally from my beginning as a florist. As an amateur or professional he was considered superior to any in England. His enthusiasm was unequalled, and he travelled into

Russia, Germany, and Holland in search of novelties; and the Lancashire florists, who reigned supreme at that period, are indebted to him for their character as florists. It was as late as 1830 that the south began gradually to creep upon us, and in a quarter of a century threw Lancashire in the shade. Another early variety was Tantarara, which soon became extinct.

As my short notice on Polyanthus was only a sketch I presume that further particulars will be acceptable to the readers of the Journal. The Polyanthus as a spring flower generally makes its appearance when the garden is, comparatively speaking, destitute of that brightness which it afterwards assumes. The plants by many are considered difficult to grow. This is a mistake, as they need but little attention beyond that of providing a suitable moderately shady situation for them. The Polyanthus cannot bear severe frosts, and the amateur will do well to protect the plants with a frame, giving them all the air possible during the winter months. In summer a copious watering late in the evening will prevent that formidable enemy the red spider from destroying the collection. The Polyanthus likes a strong soil, and yet not a clayey one; and if a little peat were mixed in the compost it would add much to their healthiness. In spring loosening the earth with a small hand fork and applying a top-dressing of old manure would make the blooms attain a large size. Emmerton, a noted florist in past years, gave many descriptions of compost, but the best of all is to study the nature and habits of the plant in its original state, and then no amateur will err.

The properties of a fine Polyanthus are as follows:—The stem ought to be strong, elastic, and erect, of such a height that the truss may be above the leaves of the plant. The footstalk should be stiff and of a proportionate length to the size and quantity of the pips, and not less than five in number, that the truss may be close and complete. The pipe, tube, or neck of the petal should rise above the impalement, be short and finish fluted in the eye; the anthers should cover the neck of the tube—that is what is called by florists a thrum eye; when the style shows its stigma above the anthers this is called a pin eye, and is rejected by all modern florists let its properties be ever so good. The tube should be round, of a bright colour well filled with anthers bold and distinct. The eye should be round, of a bright clear yellow, the same colour as the ground. The ground colour or body should be dark resembling velvet. There are also some which are red in the ground and possess all the properties of the dark-coloured; these varieties are not esteemed by florists. The dark forms certainly look richer, but yet if all the other properties are correct I cannot see why they should be despised, as they form a contrast to the others. The pips should be large and of rich and lively colours, and every pip ought to be of one size, lie flat and smooth as free as possible from ridges or fluting, and consisting of five or six heart-shaped segments. The lacing and the eye should be all the same shade of colour, and go perfectly round each petal and down the centre of each division of the limb to the eye, and should the edging not extend to the centre of each division it is a great defect.

Polyanthuses are generally repotted at the latter end of July when the weather is showery, and the plants are then divided and the tap root shortened, also they should be well shaded, supplying water only when they appear to require it. They require protection from inclement weather until March, when they may have the advantage of gentle showers. Those amateurs who grow for exhibition must thin the flower buds when they have sufficiently risen from the foliage, leaving one or two more than the number required, preserving the outermost.

In order to obtain good seed, and such as is likely to produce good varieties, you must plant some of your best varieties in a shady border any time in the autumn or early in the spring. In warm and dry weather these plants should be watered every other evening. When the seed vessels begin to open the watering should be discontinued, the seed is then nearly ripe. At this period the plants should every day be examined, and such heads as appear quite brown with their vessels opening should be gathered, otherwise the best seed will be lost. The seeds being thus carefully collected should be spread upon paper in a warm room, taking care that they are perfectly dry before they are sown, which must be done early in the spring in a cold frame, and cover them slightly with earth, and do not allow the soil to become dry. Many cover the soil with damp moss until the seed appears to be vegetating.

In the following remarks it will be seen how little has been done for nearly sixty years for the improvement of this beautiful flower. In 1821 the only Polyanthus exhibited that are now known were Stead's Telegraph, Fletcher's Defiance (scarce), Yorkshire Regent, Emperor Bonaparte, Crownshaw's Invincible, Turner's Princess, Beauty of Over, Pearson's Alexander, Cox's

Regent, Fillingham's Tantarara. In 1822 the following were added to the list:—Eckersley's Jolly Dragoon, and Nicholson's Bang Europe. In 1826 Collier's Princess Royal, and Nicholson's Gold Lace. In 1833 Buck's George IV., Clegg's Lord Crewe, Sir Sidney Smith, Yond's Independence, Maud's Beauty of England, Bullock's Lancer, and Faulkner's Black Prince was in existence. In 1840 Hutton's Lord Lincoln, and Barrow's Duchess of Sutherland. In 1844 Nicholson's King, Gibbon's Royal Sovereign, Clegg's Lord John Russell, Barrow's Duchess of Sutherland, Saunderson's Cheshire Favourite, Hutton's Lord Raneliffe, and Barnard's Formosa. In 1846 Hall's Premier Peel, not distinct from Lord John Russell. The following were known in 1852:—Buck's George IV., Bullock's Lancer, Cox's Regent, Hutton's Lord Raneliffe *alias* Prince of Orange and Golden Hero, Tillingham's Tantarara, Nicholson's Gold Lace, Nicholson's King, Pearson's Alexander, Stead's Telegraph, Brown's Free Bloomer, Clegg's Lord Crewe *alias* George Canning, Collier's Princess Royal, Saunders' Cheshire Favourite, Crownshaw's Eclipse, Crownshaw's Invincible, Crownshaw's Exile, Hutton's Earl Grey *alias* Lord John Russell, Maud's Beauty of England, Nicholson's Bang Europe, Hutton's Earl Lincoln, and Addis' Kingfisher.—JOHN SLATER.

THE POTATO CROP IN THE WEST OF IRELAND.

THE early varieties here have produced abundant crops and of good quality. The later varieties, such as the Scotch Champion and Magnum Bonum, appear better than has been seen in this locality for years. All the late crops that I have seen are free from disease at present.

The early varieties have suffered a little for the past two weeks, but as yet it is not extensive. I have this season watched the progress of the Potato, and have been careful to note the first symptoms of disease that appeared among those under my care. On the 16th of July I observed on the lower leaves of the Early Rose a number of spots resembling mildew; on the 19th it had spread considerably, still retaining the same appearance. A few days later the leaves became shrivelled, and the disease had extended down the stem to the ground level. Then I had the crop lifted, and as yet there is not one tuber diseased. The above were growing side by side with Magnum Bonum, which has not a speck on them.—A. CAMPBELL, *Ashford Gardens*.

GREENHOUSE ROSES.

ROSES are always acceptable, but the great charm of Roses under glass is that of affording flowers preceding those in the open ground. For producing grand blooms plants in beds are better than those in pots. The border may be 3 feet wide, 2½ feet deep, with a drain pipe its full length, and having a proper fall and outlet. At the bottom 9 inches of rubble may be placed, and over that a layer of turves grass side downwards, the remaining space being filled with turfy loam to which has been added a twentieth part in equal proportions of charcoal and half-inch bones. This will suit every kind of plant except those requiring peat. The plants should be turned out, and if worked they should be planted so low that the junction of stock and seion will be 2 to 3 inches beneath the surface. If there is not convenience for forming a border inside, the plants may be placed outside and the growths introduced through holes in the front, ends, or sides of the house.

The after-treatment consists in supplying water liberally, and liquid manure occasionally or a little guano may be sprinkled on the surface of the soil and washed in. The growth should be encouraged by mulching the surface of the border with short manure. In winter the border must not be allowed to become excessively dry, as some varieties will afford blooms in winter. Syringing is unnecessary. Very little pruning is necessary, only superfluous shoots must be removed, encouraging strong shoots from the base to take the place of old enfeebled growth, which should be well thinned out after the principal spring bloom is past. The secret of Rose-growing under glass is plenty of light. Roses do not succeed when shaded by other plants, and those trained to the sides, ends, or roof should not be more distant from the glass than 12 to 15 inches.

Only the best Roses should be grown under glass, and none is more worthy than Gloire de Dijon, which produces blooms nearly all the year round. Maréchal Niel is fine among the yellows; buds, half-blown or full flowers, are beautiful. Cheshunt Hybrid is the third indispensable Rose for roof-covering, giving its cherry carmine flowers profusely in spring; and Climbing Devonensis with its lovely creamy white flowers is very suitable. The purest white is Innocente Pirola, in the way of Niphetos. Perle des Jardins, straw-coloured, is one of the finest of Tea Roses; Belle Lyonnaise, canary yellow; and Paul Nabonnand, rose, are all

suitable for covering roofs and give an immense quantity of flowers when established. For the sides or ends for planting-out Niphetos with fine nearly white flowers is seldom out of bloom, and is one of the most reliable; Sombreuil, pale lemon, nearly white, very fine; Marie Sisley, white tinged with yellow, one of the best; Mrs. Opie, rosy carmine; Duchess of Edinburgh, crimson; Isabella Sprunt, sulphur yellow; and Letty Coles.

The above varieties will afford flowers more or less all the year in an ordinary greenhouse, and such beauties as are seldom seen on pot plants, besides occupying positions that would otherwise be devoted to climbing or twining plants that do not afford such acceptable flowers for cutting. I have but little experience of Hybrid Perpetuals planted out in the greenhouse. Those that do the best are Alfred Colomb, Marquise de Castellane, La France, Boule de Neige, Baronne de Rothschild, Miss Hassard, and Madame Lacharme.—G. ABBEY.

SCALDED GRAPES.

YOUR correspondent Mr. Taylor writes confidently on this subject, but he does not explain the whole system of scalding or chill by evaporation, which, in common parlance, are synonymous terms. If a chill is the cause of the injury, how comes it that it rarely or never happens in the case of our most tender-skinned Grapes, but is principally confined to Lady Downe's and Black Alicante, especially the first? and in both of these scalding never occurs to a noticeable extent (hardly at all in fact) when the berries are young and most tender in the skin, but always at the stoning period, after which it ceases and causes no more anxiety. In other plants chills are experienced at all stages, but only two or three certain thick-skinned late Grapes suffer from it, and these at a particular stage only. These are questions your correspondent is bound to explain and render conformable to his theory.

Furthermore, scalding happens under the very best management, and is worse some seasons than others, the treatment being exactly the same, only that extra care is taken to prevent it. Two years ago a gardener, whose name is familiar as a Grape-grower of the highest reputation, wrote to me saying, "I never had so much scalding as this year and can't make it out at all;" and this is the common experience. Last year and this season we have had no scalding worth mentioning. Scalding, I fear, is to a certain extent connected with the stoning process, and a seed will usually be found embedded in the scalded part of the berry.

I am afraid I and many others must plead guilty to the lazy plan of admitting air to the vineries at night, and of applying fire heat, if necessary, to render that practicable.—J. SIMPSON, *Wortley*.

THALICTRUMS.

THIS is a small genus, the members of which bear great resemblance to each other when growing, differing principally in size and height. Their compound foliage is very pretty, and from its resemblance to the fronds of some of the Maidenhair Ferns they are useful for mixing with cut flowers or for bouquet-making, whilst as ornamental border or rock plants their leaves afford a pleasing contrast to all the surroundings. They are distinguished by their total want of petals, and absence of any appendage to the fruits, leaves deeply bi or tri-pinnate; flowers mostly small and borne on dense panicles or racemes. The foliage of most of the species resembles that of *Aquilegia* in miniature, from which comes the French name of Columbine plumeuse, applied to *Thalictrum aquilegifolium*. They are showy in the mass when in flower, but as their greatest beauty consists in their foliage, the flower buds should be pinched out in order to strengthen the leaves. Almost any ordinary garden soil will suit the more robust-growing species. For the smaller, which are planted amongst the alpins, use sandy loam and peat in about equal parts. *Thalictrums* like moisture, but not stagnation; so bear in mind, therefore, when selecting a nook or fissure in the rockery, that a moist and genial site is selected, or very little foliage will remain on the stems.

Thalictrum anemonoides.—This is a charming little species for a moist fissure in the rock garden. It seldom grows higher than about 4 inches, and therefore will require a little extra care. Unlike most of the *Thalictrums*, this is an ornamental flowering plant, the blooms being about an inch in diameter and pure white. April and May. North America.

T. alpinum.—Another pretty little species, attaining a height of about 10 to 12 inches. The leaves are biternate and glaucous. It bears a lax raceme of pendulous flowers, which we advise to be kept picked off in order to increase its leaf-development. Europe (Britain).

T. flavum.—This is another of our English weeds; nevertheless

it forms a nice contrast with other plants, prefers a moist situation, and may be allowed to grow up and flower, as it produces ample foliage, the leaflets of which are large, cuneiform, trifid, acute, and dark green. It grows about 4 feet high, producing dense panicles of its yellow-stamened flowers. Europe (Britain).

T. foetidum.—A beautiful small-leaved species, which if allowed to flower becomes somewhat straggling on account of its simple stem, but if pinched and made to produce more shoots it is very handsome; the leaves are compound, with small downy dentate segments. The elegance of its contour is very charming. Siberia.

T. minus.—This plant so much resembles *Adiantum euneatum* in general outline that no garden should lack it; its merits cannot be too highly extolled as an ornamental-leaved hardy plant, as its foliage may be employed with advantage wherever that of the Fern is applicable, and that, too, without so speedily drooping. Strange to say it is a native weed, and yet no more elegant plant in its way can be found; added to this it is by no means fastidious, but will thrive in almost any soil and any position. Europe (Britain).

If the borders are extensive and more variety of these plants should be liked, there are such good species as the following to choose from:—*T. purpurascens*, *T. glaucum*, *T. aquilegifolium*, *T. rugosum*, and *T. majus*, all more or less beautiful.—H. G.

AUTUMN TREATMENT OF FRUIT TREES.

PROBABLY there never was a year when fruit was such a general failure throughout the country as this, and in nine cases out of ten the cause is attributed to last year's badly ripened wood. Everyone who has observed the fruiting results of different grades of ripened fruit-tree wood know that the two extremes produce the two extremes—the one a full crop, the other scarcely any. Unripe wood produces few flowers, and these rarely form fruit. Last year the Peach and Nectarine trees which retained their leaves until January did not bear one single blossom this spring. They are now making much wood, and if our sunless humid weather lasts they might probably retain their leaves throughout the winter again, but we will treat them now as we treated others about this time last year with satisfactory results. This consists of cutting back, disbudding, and thinning-out all the weak shoots, and nailing-in only the best, about 6 inches or so apart, against the wall.

No time should now be lost in doing this, and all kinds of fruit trees are benefited by this operation. Indeed in my opinion this is the only chance we now have of securing wood anything like ripe in autumn or a crop of fruit in spring. Bad although the weather may be during the next two months, the wood of all kinds of trees must certainly be benefited by being as well exposed as possible to both air and sun, and any labour spent in doing this now is sure to be well paid for by-and-by.—M.

EXHIBITING ORCHIDS.

A SUBJECT of peculiar importance to exhibitors, and one that urgently requires consideration, was introduced by Mr. Bardney on page 433 of the last volume under the title of "Notes about Exhibiting." He discussed in his customary practical and sensible manner the advisability of awarding prizes to so-called specimen Orchids, which really consist of several distinct plants, and cited as an instance the collection for which the first prize was awarded in the amateurs' class for nine specimens at the Manchester Show. Those "specimens" were the most remarkable examples of packing, or rather of planting, that ever came under my notice, and it was not at all surprising that the judging was very closely criticised. Large boxes were employed, and in these the Orchids were planted out, some containing about a dozen plants, the *Masdevallias* being particularly notable from their being carefully arranged in lines. The plants were all small but generally in very good condition, the flowers also being large and the colours bright, but that is all that could be said in their favour. However such "specimens" may suit the projectors of exhibitions, their admission in competition with single plants is manifestly unfair to growers who have not large numbers of plants at their command or means of obtaining them, and yet may be really better culturists than their more fortunate neighbours. Certainly the collection Mr. Bardney referred to was an exceptional one, and in some cases it is by no means easy to decide whether the specimen is "made up" or not; but in the instance under notice there was no doubt whatever, and therefore it affords a good opportunity of pointing out the evil of the present system, and also of suggesting a remedy. That it is an evil is generally admitted, and I am aware that some of the most noted exhibitors of Orchids fully recognise it as such, and would

most readily welcome an arrangement by which more justice could be done to the cultural skill of the exhibitors.

The principal object of those who devise the schedule of a horticultural society is, or should be, to so frame the classes that the best possible display can be procured. This object would rarely be attained if "packed specimens" of Orchids were entirely excluded, for they frequently contribute considerable attractions to the shows of the metropolitan and principal provincial societies; therefore some plan must be adopted by which the customary display will be produced without bringing single and "made up" specimens in competition in the same classes. It appears to me that there are two ways in which this might be effected—either by devoting one or more additional open classes to single plants, or by stipulating that the amateurs' classes shall not contain any packed specimens. The former would perhaps exceed the means of many societies, and on that account the latter would probably prove more generally applicable, as the disadvantages of the present system fall more heavily upon amateurs than nurserymen. The prizes could be offered in the "packed" classes, either for a group of Orchids to occupy a determinate space, or for a specified number of pots or pans of Orchids not to exceed a certain diameter. By this means every encouragement would be given to exhibitors of all kinds, and the display would be equally as good, or in some instances better, for many growers would be induced to compete when they knew that they had not to contend with numbers, but with size and merit only.

Difficulties would probably occasionally arise in determining whether specimens were "made up" or not; but these would be comparatively few, and with ordinary care, relying upon the honour which the majority of exhibitors possess, little inconvenience would be felt. At all events, I am persuaded the judges would be able to give more satisfaction than is possible at present, and that would be no inconsiderable gain. I offer these suggestions with the desire that some of the readers of the Journal will give the subject their consideration, and if any better course out of a difficulty can be proposed it will be most welcome.—N.

SUTTONS' SEED TRIAL GROUNDS.

IN Messrs. Sutton & Sons' seed trial grounds at Reading there are at the present time a great number of annuals and perennials in bloom, which are both interesting and instructive to the visitor. The kinds sown are similar to those distributed to their customers. As a rule the strains are very good, and, what is of great importance to all concerned, are wonderfully true to name, a few "rogues" only being seen. All are well grown and allowed plenty of room, the result being very sturdy plants, which produce seed of the best description. As may be imagined, the masses of various colours produced by the earliest-flowering Stocks, Zinnias, Marigolds, Petunias, Lobelias, Verbenas, Violas, Phloxes, and others, are strikingly grand. The Stocks and Asters are sown where they are to flower, and none could be better than the plants thus grown. Lobelias are very true to name, some of the newest varieties being unusually compact. The strains of single Petunias, *P. grandiflora* in particular, are remarkably good, the flowers being large, of good substance, freely produced, and very rich and varied in colour; many good doubles are also obtained from seed. The centres of two large beds are filled with a variety of Phlox *Drummondii*, designated Dwarf Chamois Rose, which is destined to play a very important part in the future flower garden arrangements. In habit it resembles *Silene compacta*; the flowers are of a pleasing shade of rose colour, very freely produced from the commencement of June till late in October, it being really half-hardy. It comes perfectly true from seed, and this is sown during January, the seedlings being planted out early in May.

The beds of seedling Verbenas are extremely beautiful. The growth is vigorous and clean, in marked contrast to what is usually the case with those plants propagated by cuttings. The seed germinates freely in heat, and one packet will give a number of handsome varieties. Great numbers of Dahlias are grown here, and these, too, may easily be obtained from seed, the same remarks applying to the varieties of the useful Delphiniums. All the best named varieties of the double Pyrethrums are grown, which, by being cut down immediately after flowering, bloom three times during a season. The above by no means exhausts the attractive plants to be seen either among the annuals, perennials, or herbaceous plants.—A VISITOR.

TRANSPLANTING WINTER BROCCOLI.—The rich fresh soil left after digging early Potatoes I find excellent for winter Broccolis, and no time is better than the present for planting them. I have been planting some of Snow's Winter White, which for an old variety I found during the last two severe winters much superior

in resisting frost to many other varieties. Excellent, too, but scarcely so hardy was Veitch's Self-protecting. In many of the gardens around Knight's Protecting and Dilcock's Bride are still preferred for early spring use. A most important point in planting Broccoli now is that the ground, instead of being forked over and made loose and friable, should rather be tramped and left level after the Potato crop is removed. If fine heads and less foliage is desired the ground must be firm. This was recently pointed out in the Journal by Mr. Wright.—W. J. M., *Clonmel*.

BRIGHOUSE HORTICULTURAL SOCIETY.

A PREDECESSOR of mine once bought some famous (as he thought) Devonshire cider in bottles, which he brought home in triumph. It fizzed and creamed like champagne, and he gave a glass of it to an old gardener who had lived on rough Dorset cider all his life, "Well, sir," said he in reply to the question how he liked it, "I don't believe there is an Apple in a hogshead of it." I am afraid that much the same sort of thing may be said of these remarks. I sit down to write a description of a Yorkshire flower show, but I am afraid that very little will or can be said about what should be the most important part of such an exhibition, and that is the flowers.

There were flowers much as there is sawdust at a circus, but they bore about the same relation to the rest of the entertainment as the former does to the daring riders who jump through hoops and all the fun of the show. We had horses, dogs, cows, pony racing, horse racing, horses in traps, and roadsters, agricultural horses, and every kind of quadruped except donkeys.

The flowers were, alas! very poor. But what can one expect after the weather we have had? If you want to know what the winter has been come to the West Riding of Yorkshire; here you will see Conifers killed, such shrubs as the Aucubas and Euonymus as brown and withered as if they had been burnt with an iron. The weather, too, during the so-called summer has been fearful. Nearly every day till this last week we have had heavy downfalls of rain, and there has never been really hot sunshine.

A man who lives on the moors told me the other day, that up there they had "nine months of winter and three of cauld weather," and he never spoke truer words. Last year another man who keeps an inn at the entrance to the moor which crosses Blackstone Edge told me they only had one fine day, and that was on the 12th of August. There is great humour in these Yorkshire tykes, and no end of fun to be derived from going among them. You may see this from some of the signs at the public houses. One that I found in a narrow bye street at Halifax may be mentioned. There was written up in gold letters "Good ale given away here to-morrow, but a bird in the hand is worth two in the bush." A very common name in this district for a public house is "The Fleece." How this must amuse a teetotaler; it is so very appropriate here, where hard drinking is so prevalent.

The only flowers that struck me as worth noticing at the Show at Brighouse were the Fuchsias. There is here a family called Kershaw who are noted for being good gardeners. They all keep nursery gardens, and are enthusiastic growers of plants. One of these, the son of the founder of the family, J. H. Kershaw, showed some magnificent Fuchsias, the best of which was the Earl of Beaconsfield.

The cut flowers were very poor. The Roses made one roar with laughter. "They look, Jack," said a witty brother of mine, "as if they had crossed the Channel and been masted for insubordination." The Asters were about the size of Pinks. The herbaceous Phloxes appeared to have shared the bed of the owner, or to have been the battle ground of all his neighbours' cats. But they all took prizes. The Judges were very merciful, and I am glad I was not one of them.

The trotting and leaping were first-rate, and so was the music. But why, can anyone tell me, why does the band here always play the Hallelujah Chorus during the racing? Surely poor Handel never intended his divine strains to furnish inspiring music for horses to trot or gallop to; yet for years I have heard this grand Chorus played at the same time. It does sound so very droll. A reason may be why so much sacred music is introduced, that the field is next to the church. If so, the compliment is a very delicate one indeed.—WYLD SAVAGE.

AURICULAS FROM SEED.

As the seed of these beautiful flowers is now ripe and sowing must now commence, I propose, in answer to several inquiries, to give particulars of my mode of sowing and after-management of the seedlings. The following points must be particularly attended to:—Never sow the seed deeply, or it will not germinate until by

some accident it is brought near the surface, when probably a small proportion of the seeds may start. The surface of the soil must not be allowed to become dry, or the seedlings will perish; whilst, on the contrary, if kept too wet the plants are liable to damp off, or canker will commence in the young rootlets.

My plan of sowing the seed is as follows:—I procure light boxes about 15 inches long by 12 wide, and not more than 3 inches deep inside. I bore a number of holes half an inch in diameter through the bottom of the boxes; I then place a drainage of potsherds in the box fully an inch deep, and on this a layer of dead leaves (not decomposed). In the absence of leaves I employ short straw, old thatch, or any substance that will prevent the soil from stopping the drainage. The boxes are then ready for the compost, which consists of the following substance:—Two parts good strong turfy loam free from peat or sand, two parts manure—decayed cow or horse dung two years old, free from worms or insects; and two parts leaf soil, silver sand, charcoal, or burnt refuse in equal proportions. The sand should be as coarse as it can be obtained, and the charcoal in lumps about the size of peas. This compost requires passing through a half-inch riddle. The boxes must be filled within half an inch of the top, pressing the soil firmly down, and on the surface a thin layer of finely sifted compost containing a good proportion of silver sand. I level the surface with a trowel. The seed is mixed with dried silver sand, and then sown thinly and evenly. After sowing the seed the soil is moistened with water from a very finely perforated rose, allowing the water to descend on the box in fine spray until the whole of the compost is thoroughly supplied. The boxes are covered until the seed germinates, when I sprinkle over the seed a small quantity of the finely sifted compost just sufficient to cover the seed. When the plants appear they must be gradually inured to the light, carefully shading them from sun or drying winds. A frame facing northward is very useful at this time.

When the plants have produced their second leaves I dibble them out $1\frac{1}{2}$ inch apart in other boxes in a similar compost, but not containing so much silver sand. There the seedlings remain until they become crowded, when they are again planted 3 to 4 inches apart, where they remain until they bloom. At all times carefully remove dead foliage, keep the plants free from dust, and constantly watch for the aphides, which are very troublesome. The best mode of destroying them is to damp the plants with a decoction of Gishurst compound or soft soap in the proportion of 2 ozs. to a gallon of water. I set the boxes on a stand or table, and then syringe under the leaves as well as over the plants, and allow it to dry on them.

After the seedlings are planted out of the seed box it will be a good plan to stir the surface of the soil, sprinkle a little fine compost over it, water and shade again, when it is possible another crop of seedlings may appear. This I have never known to occur when the seed has been sown as I have directed; but no doubt when the seed is sown too deeply stirring the soil, or even lifting the plants, will bring the seed so near the surface that it will commence growth.

Carefully watch for slugs, which are very destructive amongst young plants. I take a lantern after dark and hunt for them. Do not at any time place the boxes on the ground permanently, as the worms are sure to prove troublesome. Either place them on a bed of ashes or on boards raised a few inches above the soil; and I also nail a narrow piece of wood about an inch wide and half an inch thick across each end underneath the box to prevent the drainage of the boxes becoming stopped. At no time for plants in boxes do I employ a greater depth of compost than 2 inches, whilst for seed when sown $1\frac{1}{2}$ inch is ample.—GEO. RUDD.

SUGGESTIONS FOR CHECKING THE POTATO DISEASE.

MR. G. H. WITH, F.R.A.S., Agricultural and Sanitary Chemist to the Hereford Society for Aiding the Industrious, writes as follows respecting the checking of Potato disease:—

The yearly destruction of our Potato crop, and the great loss of food which follows, render it absolutely necessary that some plan for checking, and if possible exterminating, the disease should be tried without delay. After giving much attention to the subject I offer these suggestions, with the full belief that if they are carefully followed results will be obtained which will far more than repay the trouble.

The Potato disease is owing to the destructive action of two kinds of mildew; and it starts afresh every year from seeds, or spores as they are called, which have rested during the previous autumn and winter in the ground, the Potato tubers, or the manure heap.

1, Burn the haulm and all waste Potatoes, parings, &c., not

intended for the animals as soon as possible after the crop has been raised. Unless this is done the decaying haulm and waste Potatoes may fill the ground with the spores of the destroying mildews.

2, Do not throw the haulm and waste Potatoes upon the manure heap, because the mildew spores will gain in strength by resting in the manure, and this manure will help to spread the Potato disease next season.

3, Boil for a long time all diseased, and even apparently sound Potatoes before you feed animals with them. It is highly probable that the seeds of the Potato mildews gain strength by passing through the stomach of an animal, the pig for instance. The manure of animals fed on raw diseased Potatoes and Potato parings may, for the above reason, become a powerful means of spreading the Potato disease.

4, Do not grow Potatoes on the same piece of land two years in succession. Any mildew spores which may rest in the ground from the last year's Potato crop will begin to grow about the beginning or middle of May; but they will quickly perish if they cannot find Potato plants at hand to nurse them.

5, Be sure the seed Potatoes are quite free from disease when planted. A Potato does not always show the disease on the outside; therefore it will be necessary to cut the sets, in order that the condition of each one may be seen. A few diseased plants will serve to infect acres of Potatoes in a wet warm season. Some varieties of Potatoes—notably Scotch Champion and Magnum Bonum—resist disease to a remarkable degree, though of course not entirely. Such varieties only should be planted for the main crop. First early Potatoes should be planted as early as possible, and raised as soon as ever they are marketable.

6, Use chemical manures in preference to any others for the Potato crop. Ordinary manures may, especially if brought from a distance, contain the mildew spores.

7, A Potato crop may generally be saved by pulling up the haulm throughout the whole crop as completely as possible directly the disease spots appear on the leaves of any one of the plants. Of course the tubers will not grow any larger after the leaves and stalks have been removed. They will, however, ripen in the ground (more or less according to the season), and though they may not be very large they will be fit for food.

8, To ensure success all the Potato growers of a neighbourhood should follow the above plan. One plot of diseased Potatoes may furnish spores enough in July to destroy the surrounding Potato crops.—(*Hereford Times*.)

ABOUT LIVERPOOL.

UNDER the above heading some interesting notes were published last year descriptive of some good gardens contiguous to the great seaport, brief notes of the undermentioned gardens may therefore also be acceptable. The first I will notice is

HOLLY LODGE.

This is the residence of Mrs. Berg, West Derby. The gardens are not extensive nor the houses numerous, yet they contain a general assortment of decorative plants. The lawn is the principal feature, which stretches out boldly from the front of the house, and is evenly balanced with such shrubs that succeed well in the neighbourhood. At the time of my visit I was much struck with the quantity of Hollyhocks free from disease intermixed with the shrubs in various parts of the grounds, which had a very pleasing appearance. The fruit and kitchen gardens were well attended to, the latter being clean and well cropped. The garden on the whole was in excellent order, much to the credit of the gardener, Mr. Richardson.

BANKFIELD.

This is situated not more than fifteen minutes' walk from Holly Lodge, and is the residence of Mrs. Nichol. The garden is by no means large, but is well kept. The Vines were in very good condition, especially Foster's Seedling and Black Hamburgs, from which first-rate Grapes are produced. Another house is entirely occupied with one Black Hamburg Vine (forty years old), which also runs from one end of the adjoining conservatory to the other. This Vine has been under Mr. Massie's charge for twenty-two years. It carried for fourteen years 120 bunches annually, and about a hundred annually for the remaining eight years. The Vine is still vigorous, and has improved within the last few years, its roots having free access to a new border. Peaches are well grown in two houses, the trees healthy, well and thinly trained. The conservatory contains some magnificent specimens of Camellias in tubs, while Azaleas and other plants are well grown. The walls of the garden are well furnished with hardy fruit trees, such as flourish and fruit best in the neighbourhood. Pears are represented by several varieties, many of which have been grafted, and

the same process is still carried on in season with those varieties only that prove of sterling merit and first-rate quality. Everything that is taken in hand by Mr. Massie appears to be well done, and the garden generally is as well kept as any in the vicinity of Liverpool, which affords ample evidence of the skill of its manager.

HOLMESTEAD.

This, the pleasantly situated residence of J. T. Davis, Esq., is located at Moseley Hill, four miles from Liverpool. The grounds are not extensive, but such as anyone might take an interest in. It is situated on rising ground, and commands extensive views of the surrounding country. The houses are nine in number, and filled with such occupants as are generally to be seen. The Vines are only in fair condition, and the borders shortly are to be renovated. In one of the houses I noticed a *Bougainvillea glabra* flowering profusely, and the conservatory, which is lofty and close to the house, contained a good pair of Tree Ferns. In one of the pits were a fine strain of Primulas. In various parts of the grounds where alterations are now going on are arches of ancient constructed of sandstone and entirely covered with the common Tree Ivy. In other places heaps of rockwork are formed into seats and covered similarly to the arches, and in solitary places glimpses are caught of the stone. These are uncommon, and impart a novel appearance to the grounds. The gardens are in good order, and neatness seemed the order of the day with Mr. Beesley, the able gardener.

ROSEMOUNT

Is situated in the most pleasant part of the suburbs of Liverpool—viz., Aigburth, and its worthy owner is R. G. Allan, Esq. From various parts of the grounds, especially from an elevated walk, good views of Cheshire are obtained, and beautiful glimpses of the surrounding neighbourhood. This place on the whole is rather extensive, especially the glass houses, which lay in two separate parts of the grounds, whilst the conservatory is a good-sized structure adjoining the mansion, and is devoted to flowering plants, with Camellias as permanent plant occupants. The vineries are three in number, one of them being a very large span-roofed house, and the Vines in it are two years old and have borne a few good bunches and made excellent short-jointed canes. The Rose house is a large span-roofed structure with the Roses planted out, trained under the roof, and underneath were trained plants of Mignonette, Chrysanthemums, and quantities of small standard and dwarf plants of *Laurustinus* grown from cuttings, which are strong and showing abundance of flower. Running parallel with the last house is a new stove; it is a large, light, fine house, and admirably adapted for plants. The walks are laid with fancy tiles. The house has a well-heated bed in the centre, and a substantial stage round the sides. The structure has been erected by Messrs. Webster & Sons, and I may safely conclude it is the best house for stove plants in the neighbourhood of Liverpool. There are also houses for growing Fancy and French Pelargoniums, hardwooded plants, and Azaleas. The fernery is worthy of special notice, which is artistically arranged with rockwork, designed and executed by Mr. Francis, the gardener. The rock is composed of red sandstone, and the Ferns are thriving freely upon it. *Oncidium flexuosum* appears to grow luxuriantly associated with the Ferns, which are planted out, intermixed with fine-foliaged Begonias. There are two waterfalls, which have a natural appearance dashing over the rugged rocks until it descends into the little pool beneath.

Before reaching the remaining houses I followed a winding walk, bedded on each side, and banked up with evergreens in the background. This walk leads from the mansion to the flower garden, which is formed into a square, and the beds are cut out in the turf. It is enclosed by banks of Rhododendrons and other evergreen shrubs with the entrance before mentioned, and outlet walks leading to various parts of the grounds. The one I followed led into the kitchen garden, where is the remaining portion of glass, the first being the one which now contains the stove plants, but which will eventually be occupied with Cucumbers and Melons. The next to this is a span-roofed structure, 200 feet or more long, and about 10 feet wide, divided into three compartments. One was filled with Primulas; another with Tomatoes, bearing a wonderful crop of fruit in various stages, which will afford abundant supply all winter. The last was filled with plants for winter blooming, amongst them being a number of *Daphnes* trained on umbrella-shaped trellises. The pleasure grounds, the kitchen, fruit, and flower gardens, are well managed and well kept.—W. B.

LIMNOCHARIS HUMBOLDTII.—This is an aquatic that should be more generally grown. Its flowers, which are produced nearly every day throughout the summer, may be picked with several

leaves and placed in a glass bowl, and will form a fit companion to *Marica cærulea*. It may be grown in a greenhouse during the summer months, but should be kept in a warm house the remaining part of the year, should be exposed to full sunlight if possible, and will succeed in an inverted bellglass, shallow tub, or flower pot, with any kind of soil, and fresh water once a week.—J. U. S.

NEW PEA JOHN BULL.

THIS new main crop Pea is a 3-feet blue wrinkled variety of first size and quality, raised by Mr. Laxton from a cross between

Veitch's Perfection and Laxton's Prolific Longpod. In the trials at the Experimental Garden at Girtford, where during the past season Mr. Laxton has been testing a very large collection of named and unnamed varieties, the two which have stood out most conspicuously are John Bull as a 3-feet, and Telephone as a tall variety. The former is a very vigorous but compact-growing, handsome-foliaged, branching Marrow, having very closely-filled pods containing from nine to thirteen large peas in each, and ripening a few days before Veitch's Perfection. The dry seeds are of a deep greenish blue colour, wrinkled and flat from being so closely packed in the pod. As a general Pea, for its regular

Fig. 28.—PEA JOHN BULL.

habit of growth, its handsome appearance, its fertility and rich flavour, Mr. Laxton considers this the best Pea he has raised, and unapproached by any other variety of its class. The pods, which are usually produced in pairs, have only a slight curve, and in shape and size are the *beau idéal* of a fine show Pea, being larger, deeper in colour, and less curved than those of Marvel. Sown on the 11th of March this year John Bull was ready to gather on the 11th of July.

Mr. Laxton's appreciation of this Pea has led him to adopt it largely as a stock variety for crossing with the dwarf and tall early and late varieties. From the same parentage Marvel, and

it is said also Telegraph and Telephone, have sprung, although from the size and shape of the pods and other characteristics the origin of the two latter may, perhaps, be credited to a cross with Superlative, of which variety Mr. Laxton has a very fine selection with large and better filled pods.

This is the description that was referred to on page 122 last week, but the engraving was not completed in time for insertion in the same issue.

DESFONTAINIA SPINOSA IN THE NORTH OF IRELAND.—As my residence is in the county of Donegal I have put the hardihood of

this shrub to a severe test. The largest specimen I have is 5 feet high and 6 feet through, and is now covered with its beautiful orange and yellow blossoms. I have several others from layers planted out in the borders of the shrubberies, all in perfect health. Their dark green foliage has been quite uninjured by the severity of the last two winters, though they have not had any protection during times of frost. A much larger specimen, from which I have reared all the others, was killed the winter before last. The situation is well sheltered, and the soil a rather heavy clay. I am greatly surprised that this very desirable evergreen, which is easily propagated by layers, is not in more general cultivation.—JOHN R. BOYD.

MEALY BUG IN VINERIES.

It is now some years since I was troubled with the pest referred to by Messrs. Bardney and Cakebread in your issue of the 22nd ult. In plant houses where mealy bug becomes abundant it is always difficult to dispose of it. The case of vineries is somewhat different, but in them, doubtlessly, it is introduced upon other plants, and until a vinery is cleared of all infected plants it is nearly a hopeless task to attempt cleaning the Vines. Had I a vinery so infested I would have it first cleared of plants, then deal with the bug severely after the leaves had fallen. If the first brood of the insects were carefully watched for in spring, and the Vines properly dressed previously, I should not have much fear of clearing bug from a vinery in one season, provided plants were kept out of the house.—R. M.

WE do not hesitate to assert that there are but few subjects in the whole round of gardening practice that are of more importance than mealy bug on Vines. There is perhaps no question that we have had so often to answer as, "What is the best way of eradicating mealy bug from Vines?" We do not say that it is impossible to successfully accomplish the task, but it is as near as can be impossible without destroying the Vines too. We regard mealy bug as the most obnoxious enemy of the Vine that we know of, excepting the phylloxera; and, unfortunately, we have had more experience of both insects than we would care to encounter again.

Cold water forcibly applied to every part of the Vines affected with the insect has been recommended. But we do not hesitate to say that the contest has a resemblance to that of the old lady with the Atlantic. A friend and correspondent, at the time paraffin was being recommended for insect pests in general, and mealy bug in particular, went strongly in for the remedy. He first scraped off, as closely as possible, all bark that could safely be removed from the Vines, and then dressed them with paraffin and water. The result was, that the Vines were so injured that they had to be rooted out; but the bug was left intact. The fact is, no remedy, however powerful, that can be applied in winter, when Vines are dormant, can effect the complete extermination of the bug, simply because the insect retires into crevices about the Vine where no application can reach it. Besides, after the bark of the Vine is scraped off almost to the quick, paraffin is a dangerous, indeed more or less fatal, application. The Vine is so porous a subject, and the oil so penetrating, that it is sure to be hurtful, and at the same time sure not to reach all the safe retreats to which the insects betake themselves for the winter.

Ten years ago, when rebuilding a plant stove, we put the plants into two vineries, for want of a more suitable place. From the plants the Vines got bug. In order to eradicate it we had recourse to the orthodox means of close-scraping and winter dressing, with everything we could think of that would not injure the Vines. At the same time every crevice that could be seen was filled with styptic, in order to seal up and kill the bug. But every spring, as the Vines began to grow, a fresh army, more or less numerous, of the enemy appeared. One winter paraffin oil was applied to one Vine, with the result that the Vine was seriously injured, but the insect not destroyed. The conclusion was at last come to, that if it was to be completely conquered it must be done chiefly in spring and summer, when the insect was active and to be seen.

Bug by some means got carried into a Muscat house, and by catching and killing it has for several years been perfectly free from the pest. It also found its way into a large Black Hamburgh house—we always have thought, by introducing a bought-in Vine for inarching. For four years the summer catching-and-killing system has so reduced it in this house that a whole day's most minute search results in capturing one or two, and sometimes none at all, and in having localised its haunts to a few Vines; and it is hoped that this season will see its complete extinction. Although it has rarely been allowed to get into a bunch of Grapes, it has been prevented from doing so at a great outlay of hunting

and picking. But no amount of labour should be considered too much to keep such a filthy insect from the fruit.

Our conviction is that all the scraping and dressing with insecticide that can possibly be done in winter can never clear Vines from bug, and that enough will escape any winter effort to prove a most filthy pest in summer if left to breed unheeded; and that success in this way has not, to our knowledge, been recorded. What we recommend, from our own experience and success, is to scrape thoroughly in winter, so as to remove as much of the insect as possible; to scrub the Vines with a hard brush and soapy water; then to fill up every crevice effectually with styptic, and dress with Gishurst compound at the rate of 12 ozs. to the gallon of water, and well thickened with white hellebore powder. This process does not damage the Vines, and it gets rid of all the insects that can be reached by any means. The woodwork of the vinery also, and everything about it, should be thoroughly cleansed, and, if possible, painted. Then, as soon as fire heat is applied to the Vines in spring, let the rods be carefully examined three times a week, and bugs will be found emerging from the most unlikely and minute hiding places. Of course the object is to kill them before they get time to reach the young wood and leaves of the Vine. This hunting must be persevered in all through the season if success is to crown the effort. This process will get rid of the pest; and we do not know of any other that ever has or will. Certainly, if an easier plan is known to anyone, we do not think a greater boon could be conferred on scores of gardeners who are battling in despair against bug, than that of making known the secret.

Bug on Vines is a nuisance of no trivial nature, and plants infested with it, or even subject to it—and we should like to know what plant is not—should never be allowed inside a vinery. There is nothing more easy than to get a breed of the insect into a vinery; and there are few tasks in the whole of gardening so difficult as to get rid of it. But it is quite a possible task; and that, we believe, is more than can be said in the case of phylloxera in vineyards, without stamping it out by destroying the Vines—a fact which seems to be dawning on the French, now that one-sixth of their vineyards have already been destroyed, in spite of every conceivable appliance.—(*The Gardener*.)

STOCKS FOR SPRING FLOWERING.

I DO not know any flowers more fragrant than Stocks in early spring, either when grown in pots and flowered in greenhouses, or when planted out in open borders. The true biennial Stocks, the Brompton and the Queen varieties, are most commonly known, though I have not grown either since I became acquainted with the Intermediate East Lothian. This, though rather tender, well repays any extra care that may be bestowed on it. Young plants to flower next spring are now sturdy little specimens in 4-inch pots, but it may not be too late even now to sow the seeds in the south of England. Sow them on a south or east border, covering the ground with a mat until the seedlings appear, and as soon as they are large enough prick them out near the base of a wall. They may either be allowed to flower in that position, or may be transplanted in March. To flower in pots they may be pricked-off into a rich piece of ground, and potted in 5-inch pots in the end of September, placing them in dry frames or pits about the middle of October. The pits must be well ventilated, and before severe weather commences the plants will have filled the pots with roots and be in a condition to pass through an ordinary winter without injury.

One point is very essential in their management—*i.e.*, to keep them free from damp. In the middle of winter they may be safely left without receiving any water at the roots for a few weeks. In February they will commence growing; if a pit can be partly devoted to them where they can be assured a minimum temperature of 45°, they should be shifted into 7 or 8-inch pots, employing a rich open soil. A really fine display will be the result. After being removed from the greenhouse they may be planted out in borders, where they will continue to flower until winter. I have had very good results from plants lifted in autumn from borders and potted into 8-inch pots, but these plants are not so fine as those specially prepared for the purpose.

It is important to select the plants at least a fortnight before lifting them, cutting the roots round with a spade, and lifting them very carefully and potting immediately. I keep the plants very cool for a few weeks after lifting, and then winter them in a Peach house, in which they begin to flower in February, and continue for a long time to produce spikes of their sweet-scented flowers. These Stocks are very useful, as they come into flower a second time about the middle of July and continue in bloom until the growth is stopped by cold weather.

Growing these Stocks from seed is very simple. I sow the seed early in February in boxes, or in prepared beds; in either case it is better not to give a higher temperature than 50° to 55°. When the seedlings have formed their first leaves is the most uncertain period in their life, and if grown in a high temperature they are liable to damp-off by hundreds. I seldom lose many, as ventilation is carefully attended to, and if water is required the boxes are plunged in a tank. Should the seedlings commence "damping-off" they are immediately transferred to cold frames. After being a few days there a bed is prepared in a cold brick frame by mixing together a large quantity of mushroom dung and soil, and in this the plants are pricked-out. When established they grow very rapidly, and by the end of April they are transferred to borders prepared for them. I prefer the white and purple varieties to the others, but the new crimson is very fine.—R. P. B.

A WEEK OUT.—No. 4.

CHISWICK.

ON June the 12th I visited the Royal Horticultural Society's Gardens at Chiswick, which, although not now noted for its shows, is still the backbone of horticulture in this country. Unassuming labour is everywhere in these gardens bestowed upon horticulture. Whatever the skilful cultivator can bring to light by careful well-conducted experiment is done in no uncertain manner. Whatever is necessary for comparison in respect of the most esteemed vegetables, fruits, and plants is represented by complete collections at the time of experiment, so that the merits of the several varieties is patent, and the testing of new varieties complete from the data thereby secured. That much useful work is done there deserves to be more extensively known. Much real horticultural work is done and thoroughly, reflecting great credit upon the Society's talented and urbane Superintendent Mr. Barron.

Of the multitudinous subjects provided by Mr. Barron for the instruction of Fellows and visitors a volume might be written with no little profit to the horticulturist; but I have neither the opportunity nor the capacity of describing or criticising the treasures at this establishment, but some of these noted may not be devoid of interest. In Ewing's glass case or covered wall were very healthy Vines in their second season from planting, making stout short-jointed wood, and having good firm-textured leaves, each Vine having shown a profusion of fruit, which had been reduced to about eight bunches to each rod; the footstalks of the bunches, as also those of the berries, being stout, which are among the essentials to well-swelled berries and the avoidance of shanking. The Vines were producing roots freely from the collar and were in the best possible health. The varieties were principally Gros Colman, Alicante, and Alnwick Seedling. When ripened-off the effect must be telling, as the bunches are of the size and form that swell off large berries and colour well. Against the back wall Tomatoes (Hathaway's Excelsior) in pots were promising an abundant crop of fruit. In another vinery were Vines finishing off an even crop, being serviceable bunches of fair size, good in colour and bloom. These Vines are growing in loam without any of those many ingredients considered necessary for mixing with what is here only considered necessary, the results justifying the practice. Muscat Hamburgh (Black Muscat) is proved by Mr. Barron not to be different from Venn's Muscat. Royal Ascot is considered good in every respect for pots. The conservatory, now a vinery, is very interesting, the crop of Grapes being very regularly disposed in bunches that will certainly average 1½ lb. each, the size most desirable, and such as almost invariably finish well. The Vines show fruit so freely that probably one-half only is allowed to remain for the crop, which amounts to 4500 bunches, and though carrying full crops annually the Vines were in the best of health, and may owe their fertility to Mr. Barron's practice of yearly encouraging new growth to replace older growth, a portion being cut away each season. This, whilst it does not overcrowd, is clearly the extension system modified, and one that might be followed in the case of Vines that have been planted some years with great advantage. Barbarossa (Gros Guillaume) is not found to fruit freely on the old or close-pruning system, but fruits here admirably from not being very closely pruned.

In the orchard house was a moderate crop of fruit, Galande Peach and some others being well fruited, also Downton Nectarine; but as a rule orchard trees this season, though they set the fruit well, have made much stronger growth than usual, and, as invariably happens after a sunless season, the fruits have not stoned satisfactorily. The trees, trained obliquely against the Peach wall, had very little fruit. Both Peach and Nectarine trees had very healthy foliage and no blister. Apricots were few; Plums had dropped, and pyramid Pears were very scant generally, there being a good sprinkling on some, notably Beurré Gris.

Apples were somewhat better; some cordon trees were profusely fruited. A pit full of the different varieties of Capsicum will be interesting by-and-by, the bright-coloured fruit of these plants rendering them highly decorative; and another pit was devoted to Egg Plants, also very pretty, and must come into more general use for culinary purposes. The yellow-leaved Red Currant as well as the yellow-leaved Black Currant, having fine bright yellow foliage, would be highly ornamental for planting, also useful in coverts, on account of the berries for winged game, the Black Currant being suitable for planting in damp situations. Asparagus was there, as in many other places, killed or the plantations spoiled, and Seakale was equally as bad. Early Munich Turnip showed several days in advance of Strap-leaved in being fit for use, a point of some consequence in early Turnips.

A charming bit of rockery was very gay with many plants. Some of the most noticeable were *Iberis Tenoreana*, the best of the genus, having large heads of lilac bloom. *Viburnum plicatum* occupied a prominent position, its large snow balls being very effective, this and *Hydrangea paniculata grandiflora* are two of the finest of hardy white-flowering shrubs. *Campanula pulla* with its profuse bells of brightest blue was really grand. *Veronica rupestris*, even more bright and of the loveliest blue. *Dianthus alpinus*, with its deep rose flowers spotted with crimson. *D. plumarius*, pale pink and dark ring; very fine. *Armerias* or Thrift that in pink have few equals. *Aralia Sieboldi*, introduced in prominent position, from its boldness, is telling; the Feathered Grape Hyacinth (*Muscari monstrosum*) with its large showy heads of soft purple; and a magnificent mass of *Orchis foliosa*, having lilac-purple flowers spotted with crimson, were very beautiful. Among herbaceous plants were *Potentillas*, very fine; Irises deservedly coming to the fore, for no Orchids excel them in beauty; *Delphiniums*, *Pyrethrums*, &c.

Cape Pelargoniums at Chiswick were unique. There was the original Zonal, the parent of the fine varieties we now possess; and what an advance has been made from this with its pink narrow petals and zoned leaf! Not less interesting is the original Nosegay with its still more narrow scarlet petals. *Pelargonium crispum*, one of the Cape species, is as lovely a plant as can be had for affording sprays for cutting. The double Pelargoniums were a feature of great interest, especially those from M. Lemoine; the double-flowered Ivy-leaved being very fine, especially *Beauté d'Orleans*, bright deep rose, very beautiful, the habit being very compact. Zonal and Show Pelargoniums were well represented, and there was a grand display of Tuberous Begonias in one of the houses. Those were remarkably well grown, the plants being sturdy, and carrying large highly coloured flowers with good foliage. *Pelargonium bicolor* is an old Cape species of interest, and by no means common is the very beautiful and distinct *Canna iridiflora* with rose flowers, very effective for a conservatory.

There were plants of varied description for decorative purposes, such as Palms, *Dracaenas*, &c. *Fuchsia dependens*, having bright scarlet flowers, may be mentioned as fine for pillars; and *F. corymbiflora* is equally fine for a similar purpose. In the Fuchsia house are some great curiosities, such as *F. procumbens*; the lovely *Venus Victrix*, one of the finest small decorative plants in existence; *F. conica*, small bright red flowers at the points of the shoots; *F. ignea*, orange-scarlet tubular flowers; and others of greater pretensions. Tuberous Begonias succeed well at Chiswick in beds. *Iberis gibraltarica* is the finest of all the perennial Candytufts, and *Myosotis Impératrice* Elizabeth yields to none in the brightness of its blue.

Gloxinias were a speciality, and the collection, or rather selection was fine. *Neriums* were in strong force, there being many varieties, in colours of white, yellow, rose to deep red. Plants of *Torenia Fournieri* in 6-inch pots had lovely flowers, sky blue with dark indigo spots, and is highly ornamental, being a greenhouse annual, it being spoiled by too much heat. *Fragaria indica* is a fine plant for baskets, being of slender growth, producing yellow flowers at the joints succeeded by highly coloured fruits. It is not hardy, or only in sheltered situations, otherwise this Strawberry would be a fine rock plant. Many other plants are to be seen at Chiswick which few hear of, or only occasionally by a paragraph in the press; but the best of all means of unearthing its treasures is to go and see—see plants being propagated, new, choice, and rare, for distribution among the Fellows; and if the visitor be accompanied by Mr. Barron the intellect must be dull if some new idea is not obtained and much instruction afforded. Old Chiswick has done much in the past, and is still doing work tending to advance horticulture; and may it long continue its career of usefulness, taking the lead in all matters calculated to promote the interests of gardening and gardeners.

June 14th.—My object this day was to see fruit and market gardens, but after much travelling by rail and on foot I only saw

acres of fruit trees in a pitiable condition, the trees in many instances having been considerably injured by the late unfavourable summers and severe winters. There did not appear to be enough fruit to pay the rent of the ground.—G. ABBEY.

DELPHINIUMS.

THIS extensive genus includes annual, biennial, and perennial species. The greater number belong to the latter section, and the majority are possessed of great beauty. The generic name is derived from the supposed resemblance of the spur to the head of a dolphin. The English name comes from the long spur resembling the hind claw of the skylark, and Bee Larkspur from the resemblance to the body of a large bee, which the yellow and black marginal hairs of the petals bear to that insect. Delphiniums somewhat resemble Aconites, but are readily distinguished by the prolonged spur of the calyx, which in Aconites assumes the shape of a hood; and they are destitute of the two peculiar mallet-like petals which are such a conspicuous feature in that genus. The fruit consists of one to five many-seeded follicular carpels. As ornamental border plants they have few equals. The prevailing colour is blue, and the shades of this in many instances is of such dazzling brilliancy as to render them general favourites. Many are strong-growing plants, and require support to keep them from being beaten down by wind and rain. This, however, must be done carefully and neatly, or they will be robbed of half their charms. The soil they delight in is rich loam or deep garden soil—not stiff loam, but what may be termed rich friable sandy soil. They are natives of Europe, Asia, and North America.

D. Ajacis.—This name by some of the old authorities is written Aiakis, and is derived from the more or less striking marks on the petals resembling the letters A I A I. The beautiful Rocket Larkspurs are improved garden varieties of this species, much care having been bestowed upon them by the Germans. The different forms vary in height from 1 to 2 feet or more, and present a pleasing variety of colour. The seed should be sown where the plants are intended to flower, as they do not like transplanting. Sow in March or April according to the season, and thin out to about 6 inches apart. There are numerous forms with both single and double flowers. It was introduced to England in its original form upwards of three hundred years ago from South of Europe.

D. alopecuroides.—This is a dwarf perennial form of garden origin. The leaves are palmately lobed, and the trusses or spikes of bloom are long and very dense. Flowers rather small, double, bright blue tinted with rose. July and August.

D. Barlowii is a very fine garden form, which does not produce seed. It grows from 2½ to 3 feet high. Flowers large, semi-double, dark blue, shaded with bronze, with orange centre. July.

D. Brunonianum.—This fine plant is very rare; it is also peculiar from the very strong musky odour which pervades it. It attains a height of from 6 to 12 inches. Lower leaves stalked, reniform in outline, but divided into deeply cut segments; upper leaves tripartite. Flowers large, light blue, shading to purple on the margins; centre black. June and July, and dies down rapidly after flowering. Native of Western Thibet, at 14-18,000 feet elevation.

D. Beatsonii.—Flowers in dense branching spikes; individual flowers large and very double, intensely rich deep violet blue in colour with reddish centre. Height about 2 feet. July.

D. Belladonna.—Although an old border variety this is still one of the very best; it is quite barren, and consequently there is no means of increase save by division. It is very compact in habit, the usual height being about 2 feet. The flowers are large and of a lovely sky blue, a colour which attracts and pleases every one. It commences to bloom about July, and maintains a good succession.

D. cashmerianum.—A very handsome species, attaining a height of 12 to 18 inches. Leaves stalked, palmated with acute lobes, somewhat coriaceous in texture and bright green above. Individual flowers large, rich deep azure blue, with black and green centre. July. Native of the western Himalayas at 12,000 to 15,000 feet elevation.

D. Consolida.—The wild Larkspur of the English fields from which the beautiful varieties, both single and double-flowered, of what are termed branching Larkspurs have been raised. These beautiful annual flowers should be sown where they are intended to bloom, for they dislike transplanting. If sown in autumn they are sufficiently hardy to withstand our ordinary winters and come into bloom in spring; from the spring sowing they flower in June and July.

D. elatum.—From this plant, originally introduced from Siberia, we have now an immense number of garden varieties far surpassing the normal type in beauty. From amongst these we may

specially notice *amabilis*, a very ornamental variety for the back row in a border. Height about 5 feet, with a dense branching spike of azure blue flowers shaded with rosy lilac, with orange and white centre. Coronet, height 2 feet. An abundant and continuous bloomer. Flowers rich deep blue, orange and purple centre. Herman Stenger, height 4 feet. Bright violet blue; centre petals rosy pink. Spikes dense and branching. Flowers very double. Prince of Wales, a semi-double variety, about 4 feet high, producing long dense spikes. Flowers azure blue; centre white. Nahamah, height 3 to 4 feet. A wonderful free-branching variety. Spikes dense. Flowers large, dark blue tinged with bronze; centre orange brown. M. Le Bihan, height 3 to 4 feet. Spikes very dense. Flowers large and semi-double, bright rich blue; inner petals purplish rose. Le Mastodonte, height about 3 feet. Flowers very large, vivid blue, orange and white centre; indeed there is an almost endless variety of this beautiful flower.

D. grandiflorum.—This is also a Siberian plant. Height about 2 feet. Spikes dense and branching. Flowers large, dark blue, tinged rose; centre white. July. There is a white-flowered form of this species, album, and a double form having large double dark rich blue flowers with a metallic lustre. Height 2 to 3 feet. July.

D. nudicaule.—In this plant we have a total departure from the colours of all those enumerated above. It grows from 18 inches to 2½ feet high. Leaves deeply and palmately lobed. Flowers large: sepals bright, rich, velvety orange scarlet; petals bright yellow. It blooms in July, and is a most desirable plant for the border or rock garden. California.—W. H.

THOUGH the FRUIT CROP IN HEREFORDSHIRE is almost a total failure, there is a sprinkling of Apples and Pears in some orchards. Nuts and Filberts will also be very scarce.

— WE are desired to note that the WREXHAM HORTICULTURAL SOCIETY will hold their annual Exhibition on August the 27th, when about £100 will be given in prizes. The Hon. Sec. and Treasurer is Mr. J. B. Shirley, National Provincial Bank of England, Wrexham.

— A CORRESPONDENT (MR. J. LANE) informs us that there is a fine plant of *CATTLEYA CRISPA* now in bloom at Burston Rectory, Diss, Norfolk; it has sixteen flower spikes with eighty-four blooms. The plant is growing in a basket 20 inches square, and is a grand specimen, being about 18 inches high and 45 inches in circumference. It is perfectly healthy. The Rev. H. T. Frere has also some grand plants of other *Cattleyas*, and a fine plant of *Lælia purpurata* about the same size as the *Cattleya crispa*. Orchids, Pelargoniums, and Roses also seem to be special favourites, and they are grown with much credit to Mr. Frere and his gardener, Mr. W. Bolton.

— PERHAPS the most attractive department of the Royal Gardens, Kew, at the present time is the HERBACEOUS GROUNDS, where a very large proportion of the extensive collection of hardy plants are now flowering. Among them are many beautiful species that are far too rare in gardens, and it is surprising that some of the most attractive of herbaceous plants are almost confined to botanic gardens, or the few noted collections of private individuals.

— WE have received the following letter from R. Ernest Horsfall, Esq., of Grassendale Priory, Liverpool, relating to the MELON BELLAMORE HYBRID:—"I noticed in your report of the Royal Horticultural Society's meeting, in your issue of the 29th ult., that a Mr. Sidney Ford exhibited a new Melon called Bellamore Hybrid, and was awarded a first-class certificate. I conclude this was more or less an award for merit, and therefore wish to say that the Melon in question was raised a few years

since by Mr. George Morrall, gardener to Mrs. Horsfall of Bellamore Hall, Rugeley."

— WE are desired to note that the ATHERSTONE HORTICULTURAL SOCIETY will hold their first Exhibition on August 25th, in Merevale Park, by the permission of the President, W. S. Dugdale, Esq. Numerous prizes will be offered for fruits, flowers, and vegetables.

— "W. B." states that "A gold medal was awarded to Mr. Joseph Bramham, Liverpool, by the LIVERPOOL HORTICULTURAL ASSOCIATION, for his elegant and elaborate Rose Temple. It was the finest of its kind I have ever seen exhibited." This award was made after our reporter left the Exhibition, as also was a first-class certificate for furnace fronts and fittings to the same exhibitor.

— A CORRESPONDENT has forwarded a LIST OF PREPARATIONS OF THE PHYLLOXERA by Dr. Adolph Blankenhorn, of Karlsruhe. The preparations, which are intended for microscopical observation, represent both the leaf and root forms of the insect, all the stages from the egg to the full-grown insect being demonstrated.

— WE recently noticed a plant of BERBERIDOPSIS CORALLINA flowering very freely in the greenhouse at Kew. The coral red flowers are borne in pendulous clusters, and the contrast between the brightly coloured flowers and the rich green foliage is very pleasing. We have also seen this handsome shrub trained to walls with various aspects in several gardens, and if the position be moderately sheltered it appears to thrive equally as well as in the greenhouse, and is rarely injured by frost.

— A MANCHESTER correspondent informs us that "there is now an extremely beautiful display of RANUNCULUSES AT STAKEHILL HOUSE, the residence of Mr. S. Barlow, near Manchester. About two thousand plants, all of the Persian or florists' type, are in flower, and their brilliancy is astonishing. Mr. Barlow possesses a large number of varieties including all the best in cultivation, and very ably does he grow them, for rarely are these fine old flowers to be seen in such healthy condition as under his care."

— WE learn that Mr. RICHARD KIPPIST has retired from his post as SECRETARY TO THE LINNÆAN SOCIETY. The Council will appoint his successor in October. Intending candidates should apply by letter to Mr. B. Daydon Jackson, Burlington House, Piccadilly.

— THE charming DENDROBIUM GOLDIEI was recently flowering very freely in Mr. B. S. Williams's nursery at Upper Holloway. A specimen which chiefly attracted our attention was bearing about five dozen of its beautiful mauve-tinted flowers.

— THE *New York Tribune* says, "It is authoritatively announced that the PEACH CROP in America will not be a very large one, as erroneous reports have made it, but an average crop, probably as large as that of last year. As this means the shipment of about two million baskets to this city, New-Yorkers may still enjoy the prospect of having a few Peaches now and then."

— ON Saturday last, as on several previous occasions, Messrs. Cranston & Co. of Hereford exhibited about ten thousand ROSES AT THE ALEXANDRA PALACE. These weekly exhibitions appear to be growing very popular, and the rapidity with which the blooms are disposed of early in the evening indicates the demand existing for good Roses at moderate prices.

— "A. Y." states that "DELL'S NEW HYBRID MELON is a good green-fleshed variety, which sets its fruit freely, possesses a fine flavour, and averages about 3½ lbs. in weight."

— ONE of the largest and most elegant specimens we have seen of the handsome ARAUCARIA EXCELSA var. NAPOLEON BAUMANN is growing in the conservatory at Shirecliffe Hall, Sheffield. It is 8 or 10 feet in height, in vigorous health, and well indicates the distinctness and beauty that mark the variety.

— A CORRESPONDENT writes us that MARVEL PEA is undoubtedly a great acquisition to the list of good Peas. It is a strong stout grower, being about 3 feet 6 inches in height, and a most abundant cropper, having fine pods well filled with large peas of excellent flavour, each pod containing nine peas of a rich green colour.

— AT the meeting of the Royal Horticultural Society on Tuesday last the flowers of LAPAGERIAS ROSEA and ALBA exhibited by Titus Salt, Esq., Milner Field, Bingley, Yorkshire, attracted great attention, for rarely have they been seen so fine. The flowers had been cut on the Friday previous for a garden party, but appeared very fresh. Mr. C. Anderson, the gardener, stated in a letter to the Committee that a span-roofed house is entirely devoted to Lapagerias, the display of blooms being now extremely fine. The strongest shoots of those sent had from six to twelve flowers springing from a single node; one of the largest sprays had when cut about seventy-nine flowers and buds. Both forms were uncommonly beautiful, but L. rosca was magnificent. The cultural commendation awarded by the Committee was very well deserved, for Mr. Anderson has evidently carefully studied the requirements of the plants.

— MARKET GARDENERS' GRIEVANCES.—Last Tuesday a numerously attended meeting of the principal market gardeners of the suburbs was held at the Bedford Head Hotel, Covent Garden, under the auspices of the Market Gardeners, Nurserymen, and Farmers' Association, to take into consideration their position in connection with future legislation affecting the cultivation of land. Mr. Decimus Clarke of Twickenham presided. Mr. M. Searle, the Secretary, produced a letter which he had received from Mr. Horace Seymour in answer to a request that Mr. Gladstone would be pleased to receive a deputation upon the subject. The right hon. gentleman intimated through his secretary that he should much wish to receive from the Association a written statement of their general object, when he could then consider whether the time had come for oral communication. He fully recognised the importance and propriety of full consideration of this branch of the case, which, as he took for granted, would not escape the attention of the Royal Commission on Agriculture. The meeting unanimously resolved to appoint a committee to draw up a statement of the grievances under which market gardeners were at present suffering, and to represent the same to Mr. Gladstone.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 10TH.

THE meeting of the above date, though not an unusually large one, was well attended by exhibitors. The tables in the Council-room were occupied with the various collections of plants and flowers, Messrs. Veitch's Lilies, Mr. Bull's new plants, Mr. Cannell's Coekscombs, Balsams, and Coleuses, and the Society's Tuberous Begonias forming the chief feature of the display. Messrs. Carters' collection of Tomatoes in pots in the vestibule also attracted great attention, and Mr. Harrison Weir's Grapes were much admired.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. The exhibits before this Committee were not very numerous. Mr. J. Walker, Thame, Oxford, sent a specimen plant of a new selected Pea, an extremely prolific variety. On a space of about 12 square feet the plant was bearing 306 pods, many flowers also being open at the same time. It was recommended to be sent to Chiswick. Mr. Reuben Fowler, Bedale, sent a dish of Peas, a variety with very large pods, but found to be deficient in flavour and sugar. Mr. Gray, gardener to C. Seely, Esq., Brooke, Isle of Wight, exhibited a dish of Apples, very handsome in appearance but deficient in flavour. Letters of thanks were accorded to Messrs. Charles Lee & Son, Hammersmith, for fruits of Henson's Seedling Gooseberry, and to Mr. C. Lee, Hounslow, for a dish of Vicomtesse Hericart de Thury Strawberries.

Mr. Harrison Weir, Weirleigh, sent bunches of Champion Muscat, Venn's Muscat, and Madresfield Court Muscat Grapes, remarkably well grown, the bunches and berries large and finely coloured. A silver medal was awarded. Mr. C. Turner, Slough, contributed examples of Potato Early Bird, a handsome variety that is to be sent to Chiswick for trial. Messrs. Carter & Co., High Holborn, exhibited a collection of Tomatoes in pots. About fifteen varieties were represented, including the small-fruited varieties such as Red Currant and Cherry, as well as the large forms. A bronze medal was awarded for this very interesting group. Mr. McIndoe, The Gardens, Hutton Hall, Guisborough, sent a fruit of Melon Marcellus, not of first-rate flavour but handsome. Mr. John Crossling, The Gardens, St. Fagan's Castle, Cardiff, also exhibited a Melon that was rather deficient in flavour. Messrs. Veitch & Sons, Chelsea, sent a number of plants of Seakale of the varieties Chiswick White and Lily White for comparison with the common form.

FLORAL COMMITTEE.—James McIntosh, Esq., in the chair. Mr. H. Cannell of Swanley, Kent, was accorded a vote of thanks for large collections of plants of considerable merit. Cockscombs were represented by a number of handsome plants, very dwarf, with large finely arched heads. The colours were various and extremely rich, the shades of crimson and pink being especially noticeable. "Cannell's Perfection Balsams" were also bearing large flowers of good form and of many different shades. A number of Coleuses were shown, including several fine varieties. Mr. W. Bull, King's Road, Chelsea, contributed a group of new and handsome plants, among which the most noteworthy were Dieffenbachia Leopoldi, a distinct form with velvety deep green elliptical leaves, each with a prominent white midrib; the habit was compact. Geonoma princeps, an elegant pinnate-leaved Palm; Brunsvigia Josephinae, an Amaryllid with a tall umbellate scape, bearing red flowers on long pedicels; Astrocaryum Malybo, a Palm with pinnate shining green leaves and broad pinnæ; Odontoglossum vexillarium rubrum, a deeply coloured form of that beautiful Orchid; Selaginella involvens variegata, a form of this tufted Selaginella with a few white branches; and Agapanthus umbellatus albus.

Messrs. J. Veitch & Sons, Chelsea, had a group of Liliiums, including several beautiful forms of *L. auratum*, were especially notable. *L. speciosum verum* was very beautiful, the rosy crimson tint being very clear. *L. tigrinum flore pleno* had neatly formed flowers, and *Lilium longiflorum albo-marginatum* had large pure white flowers and leaves edged with white. The neat little *Angraecum Scottianum* had several flowers. The pretty shrub *Eucryphia pinnatifolia* was also represented by flowering sprays. Mr. J. Walker, Thame, Oxon, sent a number of flowers of Dahlias, large, of excellent form, and comprising some distinct and handsome varieties. A vote of thanks was accorded. Mr. Charles Turner, Slough, exhibited about eight dozen blooms of Carnations and Picotees in very fine condition, and including a large number of handsome varieties. A pale primrose-coloured self variety named Lady Rosebery was very attractive.

From the Society's garden at Chiswick were sent a collection of plants of *Begonia ascotensis*, some of which had been grown indoors and the others outside. The flowers of the latter were rather darker in colour, and the leaves were smaller than the others, but the plants were nearly equally floriferous. A large group of handsome Tuberous Begonias was also contributed, the flowers being very large and the colours bright; also double Pelargoniums and Pentstemons. Messrs. Daniells, Bros., Norwich, sent flowers of *Godetia Flag of Truce* and *Lady Albemarle*, the latter of a bright rosy crimson tinge, and the former white. The General Horticultural Company sent a collection of handsome Zinnia blooms, very bright in colour and symmetrical in form. A vote of thanks was accorded. Mr. R. Gray, gardener to the Earl of Stanhope, Chevening Park, Kent, was accorded a vote of thanks for blooms of seedling Begonias, very bright in colour. Mr. J. King, gardener to G. Simpson, Esq., Wray Park, Reigate; and Mr. A. Eckford, gardener to Dr. Sankey, Sandywell Park, Cheltenham, contributed a number of Begonias and Coleuses. Mr. Solloway, Beaconsfield, Davenport, Stockport, sent flowers of a rich purplish blue seedling *Viola*. Robert Warner, Esq., Broomfield, Chelmsford, exhibited a plant of *Cypripedium Warneri*, a cross between *C. Schlimii* and *C. Sedeni*; the flower was of moderate size of a rosy colour.

Some extraordinarily fine flowers of *Lapageria rosea* and *alba* were exhibited by Titus Salt, Esq., Milner Field, Bingley, Yorkshire (gardener, Mr. C. Anderson). Not only were the individual blooms of great size and excellent form, but they were borne in unusually large numbers; in some instances as many as a dozen flowers were produced at one node. These superb examples were greatly admired, and the Committee accorded a vote of thanks and a cultural commendation. Messrs. F. & A. Smith, Dulwich, exhibited a collection of Balsams that were bearing remarkably well-formed flowers. The strain was commended. First-class certificates were awarded for the following plants:—

Eucryphia pinnatifolia (Veitch).—An attractive Chilean shrub with shining pinnate leaves and serrate margin. The flowers are borne in the axils of the leaves, usually two at the apex of the shoot. The petals are broad, roundish, and white, the centre of the flower being occupied with numerous stamens somewhat in the style of the *Hypericum*. The flowers possess an agreeable fragrance and bear some resemblance to the Mock Orange. It is quite hardy in the Coombe Wood Nurseries, where it thrives freely.

Lilium speciosum gloriosoides (Veitch).—Flower of moderate size; divisions narrow, reflexed, half white, the lower portion near the centre of the flower spotted with red. Very distinct and pretty.

Lilium auratum virginale (Veitch).—A lovely variety of this handsome Lily with large flowers, white, with a clear yellow band down the centre of each division.

Lilium auratum platyphyllum (Veitch).—A variety with enormous flowers, 9 or 10 inches in diameter, the divisions about 4 inches across, slightly spotted, and marked with yellow in the centre.

Begonia Mrs. Sheppard (Veitch).—A tuberous variety with large white flowers, and moderately compact in habit.

Picotee Alice (Turner).—A pale yellow ground variety, slightly streaked with reddish crimson; the blooms of good form and substance.

Picotee Ne Plus Ultra (Turner).—Also a yellow ground form, with a reddish streaked edge.

Coleus Pompadour (King).—A very distinct and peculiar variety with deeply crenated leaves, marbled, spotted and streaked with crimson, pink, green, and yellow.

Hypolepis millefolium (G. F. Wilson, F.R.S.).—A second-class certificate was awarded for this elegant New Zealand Fern, which Mr. Wilson has found quite hardy at Weybridge. It has been out in the rockery for the last two or three years, and not protected in any way. Its finely divided foliage renders it particularly attractive.

LECTURES.—During the afternoon Professor G. Henslow delivered a short lecture upon the plants exhibited. He commenced by referring to a fine group of Lilies introduced by Mr. C. Marics, collector for Messrs. Veitch in Japan. It included a *Lilium auratum* var. *platyphyllum*, with a very large blossom but with the foliage of *L. speciosum*, from which *L. auratum* is usually very distinct in having narrow leaves. Several fine plants of *L. auratum* var. *virginale* (considered the same as var. *Wittei* by Mr. Elwes), and a new variety of *L. speciosum* named *gloriosoides* by Mr. Baker, having strongly incurved petals, were also noticed. The lecturer referred to Mr. Tillery's experience in the difficulty of raising intermediate hybrids—the seedlings of *L. speciosum* crossed by *L. auratum* or *vice versa*—in either case being almost the same as the female parent. The great development of the tubercular epidermal processes in some species afforded an illustration of a method of hindering crawling insects from extracting honey, which would not be of service to the plant in not pollinating it. *Eucryphia pinnatifolia*, of which some fine blossoms were exhibited by Messrs. Veitch, is one of four species, two being natives of Chili and two of Tasmania. This diversity of habitat, like the *Fuchsias* of New Zealand and South America, appears to indicate a former union between South America and those islands long since severed, but still retaining certain species, which indicates their former continuity. A fine series of Coleuses sent by Mr. Cannell, and a variegated *Croton* from Mr. Bull, furnished material for remarks on variegation, and the lecturer suggested that possibly variegation may be referred to two distinct conditions. In the case of white or yellowish foliage it was found to be by Prof. Church an arrested state resembling almost colourless seedlings, and even a similar state to colourless parasites, so that every uncoloured cell might be almost regarded as parasitically attached to its neighbouring green cell. Brightly coloured foliage, however, was a different state, for the colouring matter was (not like green chlorophyll) in the epidermis, as it is in petals, so that the Coleus had, as it were, a transposition of colour from its proper locality into the leaves. Moreover, green chlorophyll was often present, but concealed below the purple.

A group of *Celosia cristata* or Cockscombs called for the remark that it was often impossible to distinguish between a "monster" and a "variety." This plant was in a fasciated condition, usually regarded as a fusion of several stems into one, as may be often seen in Asparagus and in boughs of the Ash tree. A certain group of plants from South America (*Podostemonaceæ*) have species where the stem seems to be normally fasciated.

Mr. Frank R. Cheshire followed Prof. Henslow with a most instructive and entertaining lecture upon the structure of the bee in relation to gathering honey and pollen from blossoms. By the aid of a number of clear and elaborate diagrams he demonstrated the general structure of the insect in a concise and intelligible manner, the mouth and tongue being carefully explained. The eye was also fully discussed and illustrated. The importance of the markings and colours of the corollas as guides and attractions to the bee in its search for honey was referred to at length, and many other interesting facts were discussed. A unanimous vote of thanks to the lecturer concluded the meeting.

MARICA (CYPELLA) CÆRULEA.

THE lovely Iridaceous plant represented in the annexed engraving is worthy of cultivation by all who possess a stove, its charming lavender and orange-tinted flowers being freely produced, and the fugacious character of the individual flowers is amply compensated by a long succession. If the flowers are picked and placed in a shallow glass dish with a few blooms of the pure white *Tabernaemontana coronaria* fl.-pl., with or without an edging of *Adiantum gracillimum*, they are fit to grace the boudoir of a princess.

Marica cærulea, like its congener *M. gracilis*, is easily propagated by division of the rhizome, each node very quickly

making a vigorous young plant if potted in a light compost consisting of peat, leaf soil, and sand in equal proportions, and plunged in a bottom heat of 80°, with a moist atmospheric temperature of 75° to 85°. When rooted each plant may be repotted into 60-size pots, employing similar compost, and again plunge them. In fourteen days the plants will be ready for shifting into 48-size pots, in which they may be flowered the following spring

and summer if the plants are generously treated throughout the growing season. At this potting a compost of a richer character should be used, consisting of fibry loam, peat, well-decayed cow manure, and sand in equal proportions. The drainage should be thoroughly efficient, as during the growing season the Marica delights in an abundant supply of water overhead and at the roots. Place it as near to the glass as possible in the stove or

Fig. 29.—MARICA (CYPELLA) CERULEA.

intermediate house, using just sufficient shade to prevent scorching. As the days shorten expose the plants to the full influence of the sun and a freer circulation of air in order to consolidate and mature their growth, gradually decreasing the supply of water at the roots, and giving just sufficient through the winter months to keep the foliage fresh. On the return of spring the supply of water and heat is increased, and in a short time the lovely flowers

amply repay the cultivator for his pains. After flowering they should be placed in pots a size larger, employing the above compost, and may be grown on to any size, or they may be flowered in the same pots for several years.—J. U. S.

RED SPIDER ON VINES.—This season I have had some Vines infested with Camellia spider. I give it this name, as I believe it

is different from the ordinary red spider. Two large Camellias that were infested with this spider were placed in the vinery, and from them it got on to the Vines. It seems to attack the upper surface of the leaf instead of the under, and it increases very rapidly. However, from Camellias sponging and syringing will banish it. The inexperienced may not have noticed that it is a spider that attacks Camellias when the foliage of the plant on the upper surface appears unsightly—browned as if by thrips—and when the under surface is quite clean.—R. M. A.

NEW AND CHOICE PLANTS.—No. 3.

ADIANTUM BAUSEI (Wills).—Of the large genus *Adiantum* there is perhaps scarcely a more remarkable form than this one, with which the majority of readers of the horticultural periodicals are now well acquainted. Numerous commendatory notices of it have appeared from time to time, but the following observations may be admissible. It is reasonably regarded as a hybrid, and I am not aware that any critical pteridologist has ventured to publicly dispute the facts advanced in support of that view, notwithstanding the peculiar opinions that still exist upon the subject of cross-fertilisation in Ferns. So far as I can learn, the mode in which it was obtained was very simple: Spores of *Adiantum trapeziforme* and *A. decorum* were sown together in one pot or pan, and among the numerous young plants produced of the two species was one that appeared intermediate in character. This was carefully attended, grew rapidly, still preserving its distinct appearance, and ultimately produced an abundance of spores. These were sown and, strangely enough, reproduced the parent exactly. This is peculiar, for few true hybrids, we are told by the scientists, are fertile, and when they are the offspring usually approaches more closely in resemblance to one of the parents. However that may be I know not, but the fact remains that this Fern, which is as much entitled to be called a hybrid as any flowering plant of which the parentage is known, is yet more fertile than many Ferns that are commonly regarded as species. These are matters of considerable interest, and notwithstanding the great advances that have been made in recent years there is undoubtedly much more to be investigated.

When specimens of *Adiantum Bausei* were first exhibited at one of the Royal Horticultural Society's meetings I did not form a very favourable opinion of it as a decorative plant, although it was honoured with a first-class certificate. The fronds and pinnules were drooping so much that the plants appeared to be either suffering from recent potting or from being insufficiently supplied with water, but since then I have seen it in much better condition. The fronds have a graceful bending or drooping habit, and the pinnules are also slightly deflexed. The plant resembles *A. decorum* in habit, but in size it is intermediate between that and *A. trapeziforme*. Its very distinct and elegant appearance can be seen to the best advantage in the General Horticultural Company's Melbourne Nursery, Anerley, where one house is now partially filled with young plants. It is very free in growth, but, notwithstanding that, it is advertised as suitable for the greenhouse; judging from my experience of it I think a stove temperature suits it better.

It bears the name of its raiser, Mr. Bause, who has so great a reputation as a skilful hybridiser.—R. L.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 9.

NEW SERIES.

WE now come to the order Neuroptera, also named familiarly the order of the Netwings, from the nervures, which are so well defined in the wings of most of the species, appearing netted or interlaced. Here, as in the preceding Hymenopterous order, we have insects furnished with four wings and capable generally of flying with much rapidity; but there is an absence of the armed tail which distinguishes many groups of the bees and sawflies, the only exception in this order being amongst the scorpion flies. Their tail weapon, however, has not the character of a sting. Dragonflies, it is true, which form a conspicuous section of the order, are popularly reputed to be "horse-stingers," and on this account some persons endeavour to keep clear of these insects. They have no wish or intention to interfere with either human beings or horses or any domestic animals; other insects are their special game, and upon these the dragonflies operate, not by a sting but by powerful jaws. The order Neuroptera is the only order of insects, we believe, that includes no species that work mischief in the garden or upon the farm; but, on the other hand, there are several genera that occur in or about gardens that by their proceedings help to reduce the numbers of destructive insects. In hotter countries than ours Neuropterous insects cannot receive

unmixed praise, for amongst them is reckoned the much-dreaded white ants or termites, species that occur not only in Africa and America but also in some parts of Europe. Fortunately it does not seem probable that any of them will establish colonies on these shores. The termites, let us note in passing, are chiefly remarkable as destroyers of wood in the south of France. *T. flavi-collis* has done much damage to the Olive and other choice trees; and in some towns of Spain, where the houses are chiefly of wood, the mines of these creatures have actually caused the downfall of old buildings. In diligence and sagacity the termites are little inferior to the ants that belong to the Hymenopterous order, while they are even more prolific.

The difficulty of forming an arrangement of insects upon the transformations they undergo is curiously exemplified by the habits of the Neuroptera. The mature insects are associated by a well-marked resemblance they bear to each other, but in some of the groups both larvæ and pupæ are aquatic, and in some they live upon the leaves or branches of trees, though in both the larvæ are mostly predacious. Then the aquatic species have pupæ that are active like the larvæ until the eve of their change, while the terrestrial species become quiescent for a time after throwing off the larva skin. This difference, however, serves to break the Neuroptera into two sections. The Ephemeridæ or mayflies are the first family, distinguishable by the inequality of their wings from the dragonflies. They have the hind wings so much less than the fore wing that they are scarcely noticeable; the body is very slender, and the tail is furnished with two or three long bristles. It is an insect that has sometimes been called the day-fly, on the supposition that as a fly it only exists for a day, and actually in the case of some of the Ephemeræ, the life of the fly seldom lasts more than a day or two; but then it must be remembered that previously the insect existed in its preparatory state for nearly a year; some estimate the aquatic life as longer than that in several species. Amongst the dragonflies there may possibly be two years occupied by the larva and pupa stage. The grub or larva of mayflies is not unlike the fly, lacking wings; on the sides are a singular row of gills by which the insect breathes and rows. Some of these larvæ are in the habit of rowing after their prey, but many of them live principally in the mud, where they feed upon decaying animal or vegetable matter. The common mayfly (*E. vulgata*) is a favourite bait for certain fish, and it is asserted that in some districts on the continent the flies of this group are occasionally swept up in such quantities that the gardeners make use of them for manure.

Dragonflies are not particularly garden insects, but they are often to be seen performing their rapid evolutions above the paths where a garden is not far distant from a stream or pond. Sometimes these flies may be noticed in places a mile or two from any spot where they could have been bred. The many insects that haunt gardens are an attraction to dragonflies, and the number that one of the large individuals will seize and kill is considerable. These are not all of them eaten "clean up;" it appears as if a large proportion of the captures are only tasted and then dropped. It is likely that dragonflies received the name of "horse-stingers," because when they were seen hovering about horses intent upon catching flies that were persecuting the quadrupeds, persons hastily supposed these were the objects of attack and not the insects. The large dragonflies pounce upon insects of all sorts, they will also seize spiders and centipedes if they have an opportunity; and since their life is not, like that of the mayflies, of very brief duration, they clear off some of the insects that are hurtful to vegetation amongst other species. They are much aided in their hunts by the peculiar structure of the wings, by which they are able to fly either backwards or forwards without turning round. The small dragonflies that are placed in the genus *Agrion*, *Colepteryx*, &c., and which repose with the wings raised over the back, although they too are predacious, have a feeble flight, and confine themselves to small prey. These are seldom noticed at any great distance from the rivulets or ditches in which the larvæ lived, and above which the flies obtain their food. To the dragonflies of this family it is that the French have given the appellation of "Demoiselles" from their elegant movements, and in the sunshine a party of them exhibiting various tints of blue, green, and gold are very pleasing to the eye.

The Libellulidæ are distinguished from the Agrionidæ by the shape of the head, which is rounded and not hammer-shaped; these also when they have settled place their wings horizontally. In most species the eyes are of extraordinary dimensions, seeming to occupy nearly the whole of the head. The genus *Libellula* in its *L. depressa*, one of our common insects, offers a good example of the middle-sized dragonflies. The sexes of this species differ in colour, the female being golden brown and the male a dull blue tint. The monsters of the race chiefly belong to the genus

Æshna, specimens of which measure 4 inches across the wings. The larvæ of all the dragonflies are voracious, and those that develop into the large species are proportionably large and strong, being able to master most aquatic insects, or even young fish. Occasionally, however, they are in their turn attacked by the water beetles and conquered. In the family *Libellulidæ* the larvæ is furnished with a singular apparatus, which has been called a mask; it is an enlargement of the lower lip, and when not in action it folds over the mouth. When near the object it wishes to seize the larvæ thrusts this forward, displaying what looks like a jointed bony tongue armed with a pair of nippers. The pupa of a dragonfly is as active as the larvæ, or nearly so, until just upon the close of its aquatic life, when it crawls up the stalk of some water plant, and remains quiet waiting for the pupa shell to burst. When this event happens the fly shows much dexterity in escaping from its prison, and in drying its filmy wings, which are quite small at first, but expand as the fly somehow forces air into them from the body. The larvæ of the *Libellulidæ* are mostly stout, those of the *Agrionidæ*, being of slender proportions, approach both in size and figure those of the *Epheméridæ* or Mayflies. The *Pilidæ* or stoneflies represent a small group allied to the mayflies, with aquatic larvæ, and perfect insects that are small-winged and of sluggish habit, therefore easily caught by those anglers who require them sometimes as bait.—C.

FLORAL DEFENCES.

THE following is the substance of a lecture delivered to the members of the Liverpool Naturalists' Field Club by the President, the Rev. Henry H. Higgins:—

A market gardener wishing to improve his strain of Cucumbers frequently proceeds to select a flower from a Cucumber plant in some points finer than his own, and to place pollen from the new flower on the stigma of a flower belonging to the plant already in his frame. The flower matures, yielding a Cucumber apparently of the old sort. He, however, sows the seeds from this Cucumber, and from them he expects to grow plants bearing better Cucumbers. He is often successful. He finds that pollen from the new flower has done its work, and the gardener for his pains now has finer Cucumbers for seed and for the market. This is called cross-fertilisation (*Xenogamy*).

What the gardener does for his Cucumbers Nature does for many of her flowers. She takes the pollen from a distant flower, and brings it home to the stigma of a flower of the same kind, but not growing on the same plant. The result is that the seeds are stronger than they would have been if the flower had been fertilised by pollen from another flower on the same stem.

How does Nature bring the pollen from a distance? Sometimes by the wind. On a sunny day towards the end of February tap with your walking stick a branch of Hazel bearing catkins—a cloud of yellow dust is carried away by the wind; this is pollen, and some of it will fall on the tiny crimson flowers borne on the twigs of Hazel bushes far away, and they will produce fine clusters of ripe nuts when the proper time arrives. All catkin-bearing and cone-bearing trees, together with Grasses and Sedges, are fertilised chiefly by the wind.

Tennyson refers to the profusion of pollen dust thrown off by the Yew tree in his "Holy Grail," near the commencement of the poem.

"O brother, I have seen this Yew tree smoke
Spring after spring for half a hundred years."

Sometimes water conveys the pollen. *Vallisneria* (fig. 30) has flowers at the bottom of pools or slow streams in Italy. The pollen flowers when ripe are detached, and, rising to the surface, the pollen floats around. The pistil-bearing flowers are on stalks like corkscrews. When about to blossom the corkscrew stem straightens upwards and the pistil flower reaches the surface, where it meets with the pollen floating and is fertilised. After a few sunny days to ripen the seed the plant begins to twist up the corkscrew stem again, pulling the flower down; and the twisting goes on till the seed case is buried in the soil at the bottom of the stream, where the seeds can germinate and grow into fresh plants of *Vallisneria*.

Some tropical flowers are fertilised by birds. A climbing plant, mentioned by Mr. Belt, in Central America

Fig. 30.—*Vallisneria spiralis*.

(*Marcgravia nepenthoides*, fig. 31) has flowers suspended in an inverted umbel, as if they hung from the tips of an opened parasol. Where the handle of the parasol would be the plant forms a cluster of little pitchers containing honey. The honey attracts insects, and the insects humming birds, which, whilst feeding under the floral canopy,

dust their beautiful heads and crests with pollen, and then dart away to fertilise other blossoms.

Most frequently the pollen is conveyed by insects. Many of us have seen in the course of a summer's walk a humble bee banded with black and gold, with his muzzle deep down amongst the purple florets of a large Thistle head. He is helping himself and the plant at the same time—himself to the nectar which he loves, and the plant to the pollen of another like flower previously visited, thereby dusting his limbs and coat with life germs of priceless value to the Thistle on which he is feeding. The insect and the plant may be varied in a thousand ways, still the object and the result of the visit are the same—the insect seeks the nectar, and the plant receives the pollen, without which its seeds would remain unproductive.

Not all insects are alike suited to fertilise every kind of plant. Some plants invite a butterfly, others a night-flying moth, whilst not a few are willing to be "at home" to a variety of flying visitors, the only stipulation being that they must be of suitable size, shape, and habits to bring with them pollen of the right kind, and to leave it in

Fig. 31.—*Marcgravia nepenthoides*.

the right place. Now, other creatures besides these desirable guests love honey, especially ants, woodlice, plantlice, earwigs, and a whole host of small creeping things which prowl everywhere and are always hungry. These, as we shall see, are in many ways unfitted to fertilise most flowers. What, then, will be the fate of a flower exposed to such marauders and rifled of its precious nectar? The gentle butterfly or the helpful bee will not care to dally with the plundered blossom; no pollen will be brought, and, so far as concerns progeny, its floral life will have been spent in vain. Hence the necessity for flowers to have guards suitable for keeping away unwelcome visitors—in other words, "floral defences." You will see at once how the subject differs from that of contrivances to attract and admit friendly visitors. The latter subject has been much longer before those of the public who are interested in such matters, and may be found fully treated in the works of Mr. Darwin, Sir John Lubbock, Dr. Ogle, H. and F. Muller, and others.

Floral defences had been much less studied when, in 1878, first appeared an English translation of Dr. Kerner's work on "Flowers and their Unbidden Guests." To this work I am indebted for many of the facts which I have the pleasure of bringing before you on the present occasion.

Perhaps the simplest of all modes of defence is seen in plants which turn their flowers away from the stem; for the stem is the only road by which a creeping thing can reach a flower. Examples are very numerous. A common Snowdrop will serve for an illustration. It must be evident that a creeping insect would find great difficulty in getting down the slender neck of the flower, and in crossing the incurved edges of the three white outer segments of the perianth, after which it would have to surmount the green-tipped segments, at the base of which on the inner side the honey lies. A bee has no such difficulty. Dr. Whewell speaks of the pensile position of the Snowdrop flower as conducing to its advantage. In his days no one had even suspected how. He calls attention to the fact that the nodding of the flower is occasioned by the force of gravity overcoming the elasticity of the flower stalk, and points out that if the earth were smaller than it is the flower would not droop so much, so that the whole mass of the earth from pole to pole is actually employed in keeping the flower of the Snowdrop pendulous on its graceful stalk.

One of the most simple kinds of floral defence is used when the pollen, nectar, and pistil of a flower are shut up in a box with a spring lid, too strong to be raised by little impertinent wanderers, but easily lifted by a friend. Such a box you have often seen in the flower of the garden Snapdragon, *Antirrhinum majus*. No ant or other small insect can raise the lid, but when a lusty bee comes he shoves his head under the lid, and shortly almost his whole body disappears. Having finished to his satisfaction the little business on which he came he backs out, his legs and body dusted with the yellow pollen from the anthers ready to be carried to another flower.

But why should an ant be unwelcome? Because its polished

armour is unsuited for carrying pollen. But even if it could carry away a few grains of pollen on coming out of the flower, what a journey it would have to take before it could reach a Snapdragon on the other side of the garden, or on another flower bed—what sandy deserts of gravel walks, what forests of Box edgings it would have to traverse, with little chance that the few pollen grains would hold on to their resting places! To the bee the journey is a small affair—the work of a few seconds. Gently press the sides of a Snapdragon flower and its mouth will open like that of a nestling bird. You may see the pistil, but may find no grains of pollen on it. Very soon after it is fertilised the flower loses its springiness, and the mouth is no longer shut. Ants may now enter and feed on the nectar that is left. The plant has no longer any interest in keeping them out.

Fig. 32.—Petal of *Nigella*.

which is turned in so as not to be seen from the outside. It is almost impossible for a creeping ant to reach the nectar; but the bee settles on the toe of the slipper, bears it down by its weight, and looses a pair of springs, which turn up the lappet with its nectar. What the bee does may be imagined; but it is far better when the time comes that it should be observed.

The protective value of prickles against intruders attempting to climb to the flower from the ground is too obvious to require much explanation. The flower head of the Carline Thistle and a few bracts from the involucre of the Corn Blue-bottle will serve to show how very decidedly Nature can give notice to a snail creeping up the stem—no road this way. Well, you see, we are observing the results of long ages of development, wherein mutual relations between animals and plants have been established; and now they are at least to some extent effectual.

Thorns, which are modified twigs, serve to protect the whole plant rather than the flower; yet the hedges in May owe their snowy honours to a plant selected, not for its beauty or its sweet perfume, but because of its strong and sharp spines. The thorns of some tropical plants are fearful weapons, and Mr. Belt mentions a double capacity in which the thorns of the Bull's-horn *Acacia* (fig. 33) defend

Fig. 33.—Bull's-horn *Acacia*.

the plant on which they grow. When young the interior of the thorn is filled with a sweet pulp, on which a very warlike ant, called the Two-coloured ant, loves to feed, making a hole for that purpose near the point of the thorn, which does not seem to be put to any inconvenience by the loss of its inside. The Two-coloured ants use the hollowed thorns for habitations, laying their eggs and bringing up their young in them. If a branch of the tree be shaken the ants swarm out from the hollow thorns in myriads, and as they both bite and sting severely no animal ventures to browse upon the branches; and a much more dangerous enemy, the Leaf-cutting ant, is never known to strip of its foliage a tree thus defended. The grateful tree in return for protection produces on its leaves little cups of honey, of which the ants are very fond; and for their more solid food each leaf bears appendages, which under the microscope look like golden Pears. The ants visit these from time to time, and when the little Pears are ripe the ants nip them off by their stalks and carry them away to their nests.

Viscid Stems and Leaves.—Many common plants are distinguished by such names as *glutinosa*, or *viscosa*, referring to the sticky surfaces of their leaves or stems, which serve to protect the flowers from the visits of woodlice, plantlice, earwigs, and other creeping things.

The Common Butterwort, *Pinguicula*, has its leaves in such a slimy condition that few insects are able to creep over them, yet it is not to be reckoned amongst the carnivorous plants. Beautiful diatoms have been found in its slime, apparently in a thriving condition.

A very curious modification of this kind of defence is found in plants which secrete a milky juice in little delicate capsules just

beneath the outermost skin of the flower stem. A species of Lettuce is an example. The ant is able to creep up the lower part of the stem without hindrance, but as soon as it approaches the flower the sharp hooklets of its feet pierce the little milk-bladders, and are soon clogged with the white fluid, which, on exposure to the air, becomes like birdlime. The poor insect, in sad trouble, passes its feet through its jaws to get rid of the sticky juice, but this only makes matters worse; the jaws become clogged, and at every struggle the claws make fresh orifices through which the milk oozes, the result being almost always fatal to the ant.

(To be continued.)

THE KNOWFIELD NURSERIES, CARLISLE.

THE Knowfield Nurseries, of the firm of Little & Ballantyne, are only a short distance from the now crowded town of Carlisle, and the route to them is very picturesque. Although the firm is carried on under the above title the only proprietor of the nursery, which has been established about eighty years, now is Mr. Watt. Mr. Baxter Smith was formerly a part proprietor, and his extensive experience was of great value to the firm, and the nursery became one of the most noted of provincial establishments. The entrance to the nursery is very imposing. The drive from the entrance, a quarter of a mile long, is quite straight, and for several years it has been a great object of this firm to render this drive as attractive as possible, and hence the side borders are planted with much taste with Conifers in great variety and of dwarf habit. Thujas, *Retinosporas*, Junipers, and Hollies in choice varieties are planted in panels, and the effect is unique. The lesson to be learnt by the visitor cannot but be useful, for he is at once impressed with the great value of such plants as are artistically disposed in this splendid drive.

At equi-distances in this drive are openings through which the visitor can inspect the several quarters devoted to the rearing of the shrubs, fruit, forest trees, Roses, &c., which are grown in immense numbers. The glass department is situated at the top of the drive, and consists of many houses filled with Vines in pots, and an excellent selection of choice fine-foliaged and flowering plants. Very noticeable were Camellias, Begonias, Gloxinias, and Pelargoniums in choice varieties; also Orchids, Ferns, new *Dracenas*, and *Crotons*, all bright and healthy. The plant department is altogether very satisfactory, and Mr. Watt intends to still further improve and develop it. There were also several houses devoted to Roses and Clematises. The propagating houses are very numerous, they are all small span-roofed. Roses, Conifers, Rhododendrons, Clematises are budded or grafted in these structures and then transferred to the frame ground, which is about an acre in extent.

The alpine and herbaceous department, which is ensconced behind tall Beech hedges, and is very complete. Anemones, Hepaticas, Pyrethrums, perennial Lobelias, Aquilegias, Anthericums, *Cypripediums*, *Delphiniums* in great variety, including *D. nudicaule*, with its charming orange-red flowers; Funkias, Geums, *Helianthemums*, *Oenotheras*, and numerous varieties of hardy Orchises, Phloxes, Potentillas, Primulas in twenty-six hardy species and varieties, and Saxifrages. *Scrophularia nodosa variegata* was very fine; it is finely variegated with white and blotched with green, is perfectly hardy, and invaluable for either spring or summer arrangements. Another plant we must not omit to mention—viz., *Lamium aureum*, with beautiful golden yellow leaves streaked with silvery white, and as dwarf as the Golden Feather. Well represented also are hardy bulbs, ornamental Grasses, Bamboos, hardy aquatic and bog plants; of the latter we observed *Aponogeton distachyon*, which flowers nearly the whole of the year. Dahlias and other florists' flowers are also grown very extensively.

Near to the manager's house, Mr. Gregg's, is the original specimen of the copper-coloured Oak, *Quercus pedunculata nigra*, raised here some thirty years since. It is surprising that this fine tree has not been more extensively planted. Its small dark serrated leaves would associate well with most deciduous trees and be of service to the landscape artist. In traversing over nearly 130 acres the visitor cannot fail to be struck with the extensive "breaks" devoted to forest trees, fruit trees, Coniferæ, Roses, which owing to the elevated position of the nurseries and their northern locale, assume a sturdy hardy character, and are available for planting in bleak or cold districts. The Corsican Pine is grown in thousands, there being an increasing demand for planting forests and woods owing to its quick growth, and also from the fact that ground game seldom touch its bark. *Abies Douglasi* is also largely represented; it has been found valuable for planting in sheltered places where Larch does not succeed. Of the latter the stock is very large, and has been mostly raised from seed collected from healthy trees grown in high altitudes in Scotland, and from Tyrolean seed.

To describe the great variety of Coniferae, ornamental shrubs, &c., is entirely beyond your space. Suffice it to say that every variety of Coniferae is well represented. Of the Abies there are over thirty forms; Araucarias, Arthrotaxis, Biotas in fourteen varieties; Cephalotaxuses, and the graceful Cryptomerias, with Piceas; whilst of Pinuses there are upwards of forty forms. The new weeping Wellingtonia pendula nova is a fine novelty, and for a specimen lawn plant it could not be easily excelled. Deciduous or flowering shrubs, and ornamental trees are numerous and well represented. There are nearly thirty varieties of Hollies, some of them fine shrubs and well suited for planting for immediate effect, the firm devoting a special attention to them.

The quarters devoted to fruit trees exceed 10 acres, the soil being well adapted for producing healthy trees of a sturdy nature for planting. Apples are numerous, but preference is given to those which are free and hardy. Of Pears there is a great collection, some double-grafted on their appropriate stocks, and every form of tree is adopted. The Rose forms an important feature, large numbers being grown for home and export purposes.

Many acres of ground are adapted to growing farm seeds, both roots and cereals. Any notice of this establishment would be far from complete without mention of the fine seed warehouses, store-rooms, and offices, which are extensive and substantial. The building in the city is the native red stone, and is of the Elizabethan style of architecture. It has a commanding and imposing appearance; indeed the firm may be fairly said to have inaugurated a new era in the street architecture of this border city. Adjoining this is a warehouse for agricultural seeds with connecting floors, each 90 feet long by about 30 feet wide; while in an adjoining street there are also three flats each 60 feet long by 30 wide, these containing the various mechanical appliances for cleansing and preparing the various seeds. In summing up our remarks we may safely say that every department bears the impress of care and skill, and the whole seems guided by a masterly hand.—B. C.

DRAINAGE OF LAND.—No. 2.

IN resuming my remarks on this subject I will first draw attention to a garden constructed a hundred years. In this I find a good main drain running through the centre of the garden with a proper fall. It is built of brick, is about a foot in width, and varying from 3 to 5 feet in depth in the garden, and of course diminishing gradually to the outlet. After leaving the garden it is possible that a drain like this has to pass through various plantations of trees before finding an open course. If such a drain does not receive yearly attention the tree roots will find their way into it, and in a short time become so matted as to obstruct the watercourse. This being the case in the main drain, smaller drains will soon become stopped, and if these are not cleared out the soil will become sour, the vegetables will not grow satisfactorily, and the fruit trees become unhealthy. To those possessing such a garden and wishing to make it profitable I offer the following advice. As early in the autumn or winter months as time can be afforded begin by thoroughly clearing out the main drain. In doing this and by paying a little attention the outlets of the smaller drains may be noticed, and save considerable trouble in tracing them after. The main course being made free, attention must then be turned to the cross drains, lifting whatever has been employed for the watercourse, cleaning them thoroughly, relaying, and then covering them with 5 or 6 inches of rough material, such as clinkers, broken bricks, or any hard substance that may be at command. In former remarks I maintained thorough drainage would be the means of bringing many crops into use much earlier in the season than in an ill-drained soil; I would now add that it is advisable to lay in a few extra drains if the soil is at all heavy.

All soils do not require the same amount of drainage, but whether the soil be of a clayey or a sandy nature it requires drainage to a greater or less degree. In the hot and dry seasons of 1868 and 1870 great difficulty was experienced in many parts of the country in obtaining water sufficient to keep many plants alive, and in Staffordshire, where I was situated at that time, a horse and man were employed in drawing water in barrels a distance of a mile and a half. Although a hard winter succeeded the latter date we obtained a good supply of vegetables the following winter and spring, and the next summer fruits of most kinds were fairly abundant.

In well-drained ground, if we have a dry period, plants and trees appear distressed, but rain soon creates a change; whereas if the drains are out of order and there is continual rain for weeks the surface soil cannot be worked and the soil becomes sodden, the roots are not in a fitting condition either to obtain nutriment to perfect fruit or to mature fruit buds for another year. In

another issue of the Journal I intend to say something about the general cultivation of the soil.—ROBERT D. LONG.

KITCHEN GARDEN.

Winter and Spring Vegetables.—Fill whatever ground is now vacant with that valuable little hardy Cabbage Rosette Colewort, 12 to 15 inches distance apart being quite sufficient, and such vegetables as Borecoles, which not only afford tops for cutting, but a quantity of side shoots until a late period in spring. Savoys may also still be planted. Complete the planting of Broccoli for spring use, also Cauliflowers for late use, with as little delay as possible, and Cabbages for autumn use; sow Tripoli Onions and Winter Spinach. A supply of Onions when the stock of spring-sown Onions is exhausted is very important, and to secure this good breadths should be sown of such varieties as Queen and Early White Naples, which come in early and are much in request. Sow the seed in drills about 9 inches apart and an inch deep, choosing a sheltered border. The larger varieties of Tripoli, Rocca, and White Lisbon should be given more room, 12 to 15 inches, the seed being sown rather liberally to meet any casualties from the attacks of grubs, &c. If the ground is light it should be rendered firm before and after sowing, and when the plants appear dress the soil with soot or wood ashes to prevent the attack of grubs, and thin the plants when large enough to about 3 inches apart. Winter Spinach should have ample room for the development of the growths—15 to 18 inches is not too much space between the rows, plying the hoe freely between the rows after the plants appear, and do not allow them to remain too long without thinning.

Lettuce and Endive.—Sow seed of Black-seeded Brown Cos, Bath Cos Sugarloaf, All the Year Round, and Stanstead Park Cabbage Lettuces, also Batavian and Curled Endive for the winter supply, the plants being lifted in autumn and planted in frames. The plants should be thinned to about 9 inches apart, and the ground frequently stirred about them to encourage growth. Tie-up the Cos varieties of Lettuces as they become fit for use to secure well-blanching hearts, watering advancing crops liberally in dry weather to prevent running to seed and to insure crispness.

Turnips for spring use should be sown in an open situation, Chirk Castle Black Stone and Golden Ball or Orange Jelly are suitable for this sowing. Periodical sowings of Radishes should be continued at fortnightly intervals, and the sowing of winter varieties—viz., Black Spanish, China Rose, and Californian Mammoth, must not be further delayed. Take advantage of suitable weather for earthing-up early planted Celery, and supply later crops liberally with water or liquid manure. When the weather is suitable take up the early Potatoes, allowing them to lie on the ground for a few hours to become thoroughly dried, then store away for use. The second early varieties should also be lifted as soon as the skins are set. If there be traces of disease on the foliage the necessity for lifting is absolute, as nothing short of this will arrest its progress. Infested plants should be lifted immediately they are noticed, clearing away and burning the haulm.

FRUIT HOUSES.

Vines.—Vines in pots intended for early forcing should be in the last stage of ripening, but if in consequence of the recent dull weather any are not maturing freely fire heat should be employed, and that with abundance of air will soon ripen them. Any that are mature will rest sooner if removed to a south wall, the canes being secured to the wall to prevent injury by wind; but measures should be at hand to protect the roots from heavy rains, as a wet condition would prove injurious, and overdryness must also be avoided. All lateral growths should be checked by pinching, the old foliage being allowed to fall naturally. Early Vines should have a dry warm atmosphere secured to them by day with abundant ventilation, especially at night, the object being to have the wood thoroughly ripe. If the wood is fully

ripe all laterals may be cut away, and some of the longest shoots be shortened back, but the final pruning must be deferred until the leaves are for the most part down. The present is a good time to renovate the borders of early houses; and where the roots are in both inside and outside borders one of them may be taken out and fresh compost supplied without fear of losing next season's crop, providing the work be quickly and carefully done, the house kept close and shaded if necessary until the roots have commenced growth. If not considered necessary to entirely renew the border the old surface soil should be removed and good loam applied, mixing with it a little charcoal or wood ashes and some half-inch bones. Young Vines planted this season should be encouraged with moisture and heat and a free extension of the laterals, as the main object the first season is to secure vigorous root-formation and a few ripened eyes at the base of the canes for cutting back to. Be careful as yet in the treatment of late varieties, such as Lady Downe's, Alicantes, and Muscats, as the change from dull weather to bright sun in a few hours may do serious injury, maintaining a temperature of 70° at night, and ventilating freely in the daytime. Hasten by every possible means any Grapes now in a later stage than colouring; but with the Grapes well advanced give an abundance of air in the early part of the day, closing sufficiently early in the afternoon to allow an advance to 90°, and before night ventilate, allowing it to remain all night. For heavy crops swelling off, supply abundance of liquid manure at a temperature of 80° to 90° to the internal borders, and keep the atmosphere well charged with ammonia by damping all surfaces, where it can be done without spotting the Grapes, every evening with guano water, 1 oz. of guano to a gallon of water. Vines with crops colouring and finishing off must be freely ventilated, admitting air at night, employing fire heat when necessary, as a warm dry atmosphere is indispensable to perfect finish in Grapes.

Peaches and Nectarines.—Trees that have been forced early for a number of years acquire a tendency to premature development, notable in this respect are Early York and other early varieties. This can only be lessened by allowing a moderate extension of the laterals, and the exposing the trees to the external air by the removal of the roof lights, or it may be arrested by the maintenance of a dry atmosphere and a somewhat dry condition at the roots; but this tends to premature ripening of the foliage, which is as bad if not worse than the loss of a few buds. With the trees fully exposed the foliage will ripen off freely, and where the roof lights are not moveable admit air to the fullest extent, maintaining a good moisture in the internal borders, and damping the house occasionally in hot weather. Some of the foliage of the trees in the earliest forced house will now or shortly begin to drop off, but do not accelerate this by brushing over the trees, only remove such as are ripened, for the purpose of destroying any insects they may harbour. Trees showing indications of weakness should have the roots bared and the soil removed, supplying some rich rather strong loam, with a small proportion of half-inch bones and wood ashes, which should be made firm, following with a good watering. Damping the trees occasionally will facilitate speedy root-action; and in case of lifting the roots, as may be necessary if they are deep, and laying them in fresh soil nearer the surface, shade from the bright sun will be necessary, with a rather close and moist condition of the house. It is as yet too early to plant fruit trees, yet all trees for Peach houses should be removed thereto before the leaves have fallen, indeed as soon as the wood is in a condition to admit of it without danger of shrivelling. It is not, however, too soon to select the trees for planting, having them marked at the nurseries for removal when in a suitable condition. Some of the best and most reliable are Hale's Early, A. Bec, and Royal George in Peaches, with Lord Napier and Elrue's Nectarines for early forcing; and for successional houses, in addition to those named, are Early Grosse Mignonne, Stirling Castle, Grosse Mignonne, Noblesse, Bellegarde, Barrington, Prince of Wales, and Walburton Admirable in Peaches; and of Nectarines, Murrey, Rivers' Orange, Violette Hâtive, Stanwick Elrue, and Albert Victor. To help trees in succession houses to ripen the wood they should be looked over after the fruit is gathered, and the shoots where too crowded well thinned out, as well as the shoots that have borne fruit this season and are not required for extension.

PLANT HOUSES.

Camellias.—The general stock will now be setting their flower buds, and any requiring repotting should be attended to in this respect before the buds are too much advanced. As to soil, good sandy loam full of fibre is the best, and where this cannot be obtained moderately fibrous peat may be employed, but on no account employ old loam or peat, as either long stacked will have the fibre decomposed. Do not break it up too fine, add sand to the extent of about a sixth, employing the potting stick so as to make the soil as firm as the old ball, merely removing the crocks and the soil not occupied by roots. Camellias do not require so much root room as most plants.

Primulas.—Plants from seed sown in spring should receive their final shift without delay, pots 7 or 8 inches in diameter being sufficiently large, whilst good plants may be grown in 6-inch pots. A compost of good fibrous loam four parts, decayed manure, leaf soil, and sand each a part, thoroughly incorporated, will suit them well. They should be placed in a house, pit, or frame close to the glass, ventilating freely, and shading in sunny weather.

Cinerarias.—The earliest plants intended for large specimens may now be shifted into 8 or 9-inch pots, but for general decorative purposes those in 6-inch pots are the most useful. Turfy loam, with a fifth of thoroughly decayed manure and a sprinkling of sand, will suit them. They should be placed on ashes in a well-ventilated pit or frame, being shaded from bright sun. Cleanliness from aphides is of primary importance in Cineraria culture, therefore dip the plants in tobacco water, or fumigate moderately upon their first appearance.

Cyclamen.—The plants will now be freely rooting, and should be shifted into larger pots where necessary, merely removing the crocks and any soil not occupied with roots. Any plants that do not require shifting should have the drainage rectified, the surface soil being removed and fresh compost supplied. Good fibrous loam with a fifth in equal proportions of decayed manure and leaf soil, with a sixth of sand, will suit them well. They should be kept in a pit or frame with moderate ventilation. Young plants should be shifted into larger pots, and growth encouraged by keeping them rather close.

FLOWER GARDEN.

The almost incessant rains during the past month have been very unfavourable to the production of bloom, but Violas and Verbenas have succeeded well. Pelargoniums have plenty of foliage but few flowers. This tendency to over-luxuriance may be lessened by removing the old leaves so as to allow the air and light to solidify the growth. Although unfavourable for the flowering varieties of Pelargoniums those grown for the beauty of their foliage were never perhaps finer, the moist atmosphere and subdued sunshine suiting them admirably. Flower gardens are now expected to be at their best. Every care should be taken to have them in good order. Rough edges of lawns must be trimmed, and the grass frequently mown, keeping all as trim as possible. Tie and support the various border flowers as they advance in growth, removing dead flowers and seed vessels. Pippings of Pinks may still be inserted, and any that are rooted may be planted out. Carnations and Picotees if not yet layered should be attended to, and sow the seed as soon as ripe in pans. Roses are now nearly over; the straggling shoots should be cut in, and every encouragement given the plants to make young wood for autumn blooming.

Propagating Bedding Plants.—Cuttings of the choice varieties of Pelargoniums—tricolor, bronze, and variegated—should at once be inserted, as if deferred until late in the season failure is inevitable. They should be inserted round the sides of pots placed on ashes in a frame in the full sun, the lights only being employed to afford shelter from heavy rain. After they have been attended to the Zonals should be commenced, for though it may be disagreeable to cut the plants directly they begin to look well, yet it is advisable to start betimes so as to have well-rooted sturdy plants before winter. Verbenas, Petunias, Ageratums, &c., strike freely in a cold frame kept close and shaded from bright sun, the plants so raised being hardier and winter better than those struck later on in heat. If stock plants of Iresines, Coleuses, Alternantheras, &c., were not kept for propagating, cuttings should at once be obtained.

TRADE CATALOGUES RECEIVED.

Wm. Cutbush & Sons, Highgate, London.—*Catalogues of Store and Greenhouse Plants and Bulbs.*

Wm. Paul & Son, Waltham Cross.—*Catalogue of Bulbs.*

John Laing & Co., Forest Hill, London.—*Catalogue of Bulbs.*

Damman & Co., Leipzig.—*General Catalogue of Plants.*

George Rudd, Undercliffe, Bradford, Yorkshire.—*Catalogue of Auriculas, Carnations, and Picotees.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Culture of Tea Roses (*Reader*).—You will gain all the information you require from Nos. 995, 998, and 1002 of this Journal.

Twin Cucumbers (*B. C.*).—We have had many specimens sent to us similar to the one to which you allude; indeed twin fruits appear to be plentiful this year.

Caterpillar on Clematis (*Rus in Urbe*).—This is the caterpillar of the Buff Ermine Moth (*Arctia lubripeda*), which feeds on a variety of plants in gardens. There is no remedy but hand-picking.

Clematis Injured (*Idem*).—We are unable to account satisfactorily for the withering of the buds and tips of the shoots. We have seen them injured by the wind, and also shrivel when the soil has been too dry for affording the support necessary for continuing free and unchecked growth. The soil may be moist enough on the surface, but is it moist below?

Manure for Mushroom-growing (*I. W. C.*).—There is no practical difference between the droppings of horses and mares at the time the droppings are collected for making up Mushroom beds. We have employed both for many years with satisfactory results.

St. Ignatius Bean (*T. Derby*).—This is the seed of *Ignatia amara*, a plant that is allied to the *Strychnos nux vomica* of commerce. The fruit is about the size of a Pear, and is covered with a thick rind. The so-called "beans" contain a large quantity of the alkaloid strychnia, which has been employed in medicine.

Various (*Flora*).—The "Green Rose" you could possibly obtain from any of the chief nurserymen. *Schinus Molle* requires a stove temperature in this country to grow it successfully. There are botanic gardens both at Frankfurt and Hamburg.

Jasminum officinale (*S. C. O.*).—Possibly this is the "common white Jessamine" to which you allude; if so, it may be allowed to grow freely during summer, and in autumn prune in the straggling shoots. It may be propagated either by cuttings or layers.

Cucumbers not Swelling (*Half-pay*).—The most likely cause of the fruit turning yellow at the neck, being crooked and bad generally, is the recent dull wet weather, and could only be remedied by gentle fire heat so as to admit of a circulation of warm air. The most reliable variety for market purposes is Telegraph; Paragon also is very good.

Mealy Bug on Stove and Greenhouse Plants (*A Victim to Bug*).—A solution of nicotine soap, 6 ozs. to a gallon of water will destroy mealy bug; the plants if small being dipped, or if large laid on their sides and syringed, turning them so as to thoroughly wet every part. The solution should be applied at a temperature of 100° to 120°.

Grapes Shanking (*J. K. Boyd*).—Removing large quantities of foliage at one time is almost certain to produce shanking or scalding, but generally the former, and is not favourable to the perfect finish of the Grapes, not infrequently resulting in deficiency of colour in black varieties.

Men Required in Garden (*Subscriber*).—Much depends upon the extent of glass and the flower garden, but as a rule a man to every acre of ground is considered sufficient, the glass being in proportion to the extent of ground as usually prevails in private establishments. Had you given more particulars our reply would have been more explicit.

Rose Foliage Eaten (*Horace*).—The leaves have been eaten and perforated by some caterpillar. Syringe the trees with tobacco water—viz., a gallon of tobacco juice diluted with 6 gallons of water, adding 2 ozs. of soft soap to each gallon of the liquid. Apply it during a calm evening.

Greenhouse Plant not Flowering (*A Subscriber*).—The few leaves you sent appear to be those of some Myrtaceous plant, but without flowers it is impossible to determine the species. The excessive luxuriance you mention is probably the cause of its not flowering. Turn the plant out of the pot, and repot it in a compost of peat, loam, and sand without any manure. Place it in a position where it will be fully exposed to the sun, so that the growth may be matured.

Liming Vine Borders (*Beauchamp Stannus*).—Having given your Vine borders a dressing of lime in spring, more will not be needed for two or three years, unless a small quantity was applied, when a similar quantity may be given

annually. Lime acts as a decomposer of animal and vegetable matter. It also affords calcareous matter, so essential to some kinds of Grapes, particularly Frontignan.

Vines for Early Forcing (*T. Andrews*).—Of the Vines you name Buckland Sweetwater and Mill Hill Hamburg are the only suitable varieties. Frankenthal can be forced, but does not always colour well, and Muscat Hamburg sets so badly that it cannot be satisfactory. Similar remarks apply to Golden Queen, which with Madresfield Court are capital midseason Grapes and good for starting in early spring. Gros Colman and Alicante are excellent late Grapes. Add to the first two named Black Hamburg, Foster's Seedling, and White Frontignan—all suitable for early forcing.

Vine Leaves Scorched (*F. I.*).—The removal of the foliage in quantity would have a tendency to induce scorching, and ought not to have been necessary had pinching been resorted to at the proper time. Never allow more foliage to be retained than there is sufficient space for, as when the leaves are crowded they cannot properly perform their functions, and their removal may, after a dull period, result in the remaining leaves being scorched.

Tomato Leaves Curled (*J. Bartlett*).—The variety is either too heavily cropped, or is less robust in character than the other that remains in a healthy state. There are traces of mildew on the foliage, and on one leaf some discoloration that conveys a suspicion that the plant is attacked with the disease similar to that affecting Potatoes. If the brown patches increase in size and number you had better cut off all the affected growths, or even destroy the plants, with the object of preserving the others that yet remain in a healthy state. We have seen thousands of plants quite ruined with the "disease." Yours, however, judging by the leaves sent, appear to be only slightly affected with the malady and may possibly recover.

Tomatoes not Fruiting (*H. T. H.*).—Many besides yourself find the "early blooms barren" on plants grown in pots under glass, and several good cultivators remove the first flowers and seldom fail to obtain a full crop, the flowers subsequently produced generally setting well. It is an excellent plan to retain only one stem to each plant, and with sufficient light for the foliage and otherwise good management heavy crops are produced. Your letter shall have our attention.

Pruning Chimonanthus fragrans (*M. P.*).—Cut back all excessively long or irregular shoots after the shrub has flowered, and train-in the branches to the wall. During the spring and summer any coarse growths can also be removed. This shrub, although of easy culture, does not usually flower very profusely unless it is in a warm border and trained to a wall with a south or south-west aspect. When too luxuriant lifting and replanting is an efficacious mode of checking it, and inducing the production of flowers.

Melon Stems Cankering (*Gardener*).—The canker at the stem and roots is caused by a superabundant supply of moisture after the stem has been for a time dry, and not unfrequently is caused by the stem being covered with leaves; or drip from the lights will cause it. Remove the leaves which cover the stem, and keep a clear space of about 6 inches from the stem all round, and if any canker appear rub it dry with quicklime, and dust it over with it after the operation. Examine the plants frequently, say two or three times a week, and if any canker continue apply fresh lime, dusting again as before, and the best results may follow.

Culture of Indigofera decora (*M. D.*).—It is of free growth, and requires the wood well ripened to ensure profuse flowering. Prune in February or March, when the plants are beginning to grow, cutting them in rather closely, or in case of old plants spur the shoots into two or three eyes of their base. Young plants will of course need to have the shoots left longer for the formation of the specimen, and being in a cool airy part of the house they will break naturally and strongly. When the young shoots are an inch long turn the plants, remove most of the old soil, and pot in the same size of pot or a little larger, and place in a close pit, shading from bright sun until the plants have recovered, then expose them to light and air, syringing with water morning and evening up to flowering to keep down red spider. When the roots are slightly matted shift into a pot 2 to 4 inches larger in diameter, providing good drainage. Water abundantly when growing and flowering, afterwards expose the plant fully to light and air, and in winter keep it dry, not, however, so as to cause the wood to shrivel or leaves to fall prematurely. Equal parts of sandy peat and fibrous loam, a quarter part of leaf soil or old dry cow dung, a sixth of silver sand, with a like quantity of pieces of charcoal form a suitable compost.

Vegetation North and South (*Rev. C. S.*).—The average summer temperature is almost invariably some degrees lower in the district to which you refer than in the south of England, and the crops are correspondingly later. We know a gentleman who remains in the south until the small fruit crops—Strawberries, Currants, Raspberries, and Gooseberries are over, and then goes to his residence in Morayshire and finds them just commencing ripening. This has been his practice for thirty years, and he has never, when the crops were good, been disappointed of his second period of fruit. Nearly all the hay is gathered in the south, and grain-cutting has commenced, but with you the corn is not nearly ripe. The difference generally holds good throughout the season, but occasionally the autumn is brighter and drier in some districts of Scotland than in the south of England, which is fortunate for you, or some crops in the north could not ripen at all.

Roses Exuberant (*Irish Subscriber*).—Thin-out the growths if crowded, retaining those that are short-jointed, removing those that are very sappy on the one hand and weak on the other. By thus admitting light and air to the foliage you will aid in maturing the growth. As you reside in a moist climate you may possibly with advantage remove the tips of those shoots that are 4 feet high, but the growths usually become firm without being stopped when they are thinly disposed. If you do not prune the plants too closely in the winter you will probably have fine blooms next year, but close pruning will result in further strong and perhaps flowerless growths.

Late Strawberries (*W. B. E.*).—Elton, Eleanor, Frogmore Late Pine, and Loxford Hall Seedling are amongst the most useful late varieties. Dr. Hogg is often late when grown in a cool position, and is of better flavour than the others. It is not safe to grow only one late Strawberry, as the varieties do not succeed equally well in all districts. Try those named, and select the one most suitable for your soil and situation. They can be had from growers who advertise in our columns. We never recommend dealers.

Roses for Chalk Soil (*M. B. D.*).—By trenebing the soil and making it good with the addition of manure to a depth of 2 feet, and covering the surface thickly with manure, all free-growing Roses will succeed in your garden. As you do not state the number of varieties you require we cannot usefully make a selection for you, but if you state the number you want to a good Rose nurseryman, stating also the nature of the soil, he will send you suitable varieties. If

the soil is very strong the Briar would be the most suitable stock, and many varieties would also do well on their own roots. We are quite ready to name some good varieties for you if you will let us know how many you require.

White Foxglove (*Risley Hall*).—The flowers had all fallen from the branch and were much withered. It appears sufficiently distinct to be preserved with the object of ascertaining if the change of form is merely accidental or not. You might also save seed from the large bell-shaped flowers, and possibly you may obtain a distinct and pretty variety.

Agave densiflora (*C. M.*).—It is impossible to advise you as to the treatment of the plant without seeing it. The most satisfactory course would be to take the opinion of a practical gardener in the neighbourhood. The fact of the Orange pips producing "apparently wild trees with thorns" indicates the tendency evidenced by all cultivated plants to return to their original form.

Vines Unhealthy (*J. T. S.*).—You have misunderstood us. We did not say the scorching of the foliage was caused by syringing too early in the afternoon, but endeavoured to inform you that it was caused by the house being too moist in the morning before the ventilators were opened. Your Vines are undoubtedly scorched, and are more liable to injury on account of their unhealthy state. The leaves, instead of being stout and leathery, are thin and flimsy, quite destitute of tissue, and this has not been caused by insects, but is the result of some fault in management or unsuitable soil. There are no insects nor eggs nor larvæ of insects in the excrecences of the leaf sent, which we have carefully examined with the aid of a powerful microscope. The Melon leaves were beyond question infested with red spider. There may, of course, be some other insects on the plants, but there were none on the leaves sent. There are no so-called "Vine bugs" on the leaf we have examined but only warts, with traces of red spider and mildew—the latter being consequent on the ruptured tissue. It is not common for red spider to "eat holes" in the leaves, but when the insects are so numerous as they were on the Melon leaves sent, they so extract the juices that a shrinkage of the foliage often follows, and occasionally the leaves appear as if roughly perforated. The same effects follow when the young leaves are much attacked, and afterwards increase in size. Neither does the Vine coccus eat holes in the leaves. Whether there are other insects or not on your Vines besides the red spider you cannot err by sponging the foliage as you propose with a mixture of softsoap and hellebore. It is our duty to inform you that you are quite in error in describing the warts on the leaf before us as "nothing more nor less than the bug or coccus in their larvæ state." We cannot tell what you have on leaves that we have not seen; but this we know, that your Vines have been mismanaged and your Melons devoured with red spider. You had better sponge the leaves now and give the Vines and house a thorough cleansing in the winter.

Various (*E.*).—If you have employed light open nets, old herring nets, for the trees, they are not the cause of the foliage falling. The trees are probably weak as well as old, and in that state the foliage is very liable to the attacks of red spider, which does little harm to young and vigorously growing bushes. The tendency of early defoliation is to restrict root-action, which renders the trees still weaker, and the fruit smaller each year. Keep your old trees till the others are in a bearing state, then destroy the former, having still younger plants coming on to maintain the supply. All the trees you name may be safely removed if they are taken up with great care, planted well, and staked securely. Evergreen Oaks, however, do not transplant well, and special attention must be given them both during their removal and afterwards. If biennials are grown in specially prepared beds, each kind having a bed to itself, they may be planted in early autumn; but if they are required to bloom in mixed borders they are preferably planted in spring, just when fresh growth is commencing. Fruit is generally small this year, the weather not having been favourable for its free development. A greenhouse with a north aspect is suitable for Ferns, Selaginellas, fine-foliaged Begonias, and even Fuchsias in the summer; also for Camellias and many other plants.

Boxes for Exhibiting Cut Flowers (*San Juan*).—There is no work published on this subject. The boxes described in the book you name will, as to size and distances of the tubes, answer equally well for Pelargoniums, and Pansies may be shown in boxes that are used for Carnations, the dimensions of which are given as follows by the National Carnation and Picotee Society:—For twelve blooms there should be three rows of four each, from centre to centre $3\frac{1}{2}$ inches; from centre to outside, $2\frac{1}{4}$ inches; outside length, $15\frac{3}{4}$ inches; width, 12 inches; depth, $4\frac{1}{2}$ inches; to be painted a bright green. The collections of sixes should be in three rows of two each, with the flowers at the same distance from centre to centre, and centre to outside, as in the collections of twelves. The collections of twenty-fours may be composed of two boxes of twelves, making three rows of eight in each row, or in one box, as may be convenient to the exhibitor, but the same space should exist between the flowers. The same boxes will also do for French Marigolds. Asters and African Marigolds may be shown in the Rose boxes, or boxes of the same size, for they are not shown on moss the same as Roses are. Carnations, Picotees, Pansies, and Asters are usually shown on white paper collars.

Ornamental Fence (*Suburban*).—Peeled oak cord-wood makes a first-class rustic fence, and its peculiar forms may be arranged to suit almost all tastes. An examination of a rustic chair will suggest something of the appearance of Oak cord-wood made into a fence; but you can have it placed to suit your own fancy, for rustic work is ornamental in proportion to its rudeness. A fence of this kind covered with Ayrshire Roses is one of the finest objects in a garden. The branches of the English Maple (*Acer campestre*), are the best of all wood to form a rustic ornamental fence; but they can rarely be had. The thinnings of Larch plantations are most used, and may be made to assume a variety of forms, the commonest of all being upright posts driven into the ground close enough to keep sheep out, with a half pole on top for capping. This is commonly known as the Scotch fence. Any joiner would suggest to you several shapes and put them together in squares, triangles, or diamonds to suit your taste.

Names of Fruits (*G. P., Hants*).—The Pear was much decayed, but appears to be Citron des Carmes.

Names of Plants (*Sal.*).—The plant resembles a stunted form of *Francoa appendiculata*. (*G. P.*).—The Rose was too much withered to be recognisable. The yellow flower is *Tanacetum vulgare*, the other is *Rhus Cotinus*. (*F. T.*).—1, *Anemone coronaria*; 2, *Leycesteria formosa*; 3, Completely withered. (*G. J. S.*).—The plant to which you refer is *Tritoma Uvaria*. (*W. R.*).—Your specimens when submitted to us were too withered to be identified. (*J. T., Stoke*).—1, *Spiraea Menziesii*; 2, Too withered to be recognisable; 3, *Astrantia major*; 4, *Habrothamnus elegans*; 5, *Veratrum nigrum*; 6, *Funkia ovata*. (*Cuckfield*).—*Achillea Ptarmica flore pleno*. (*M. Roper*).—The small fronds of the Ferns we received were quite without spores, so their names could not be determined with certainty.

POULTRY, PIGEON, AND BEE CHRONICLE.

ROTATION OF CROPPING FOR HEAVY OR MIXED LOAMY SOILS.

WE are aware that we have undertaken a difficult task in endeavouring to indicate the best rotations of cropping for heavy or mixed loamy soils, but our experience of the systems of cropping adopted upon various loamy soils has been so extensive that our remarks may be the means of inducing the home farmer to consider the subject attentively. One of the chief difficulties we shall have to contend with will be difference of soil, situation, and aspect. The soils, and the variations from flat to hilly land, even where the soil is similar, will be sure to influence the cropping; we shall therefore endeavour in the various divisions of soils to name them, in order that each may the more readily be treated by different modes of cropping. In carrying out our intentions we shall, however, be obliged to allude incidentally to the system of stocking as well as cropping, for it is important that wherever stock is kept it should be shown practically how it is made suitable to both soil and climate.

We will first consider the treatment of clay soils. These vary much in consequence of the difference of the subsoil, yet there is a similarity among them which either excludes sheep from the land, or at any rate from consuming roots upon the land in the winter months. Still on many farms, especially those situated upon a chalk subsoil, sheep are kept in large numbers. Let us first discuss a rotation of cropping for such soils, including a provision for sheep feeding off green crops during the summer months; and we must here remark that the present time is the best, not only for setting out the rotation, but also for altering any mode upon which a farm may have been previously conducted. We will illustrate our advised system by the cropping of a farm of 200 acres of arable land. First year a preparation by autumn fallow, sown with Rye, Trifolium, and winter Vetches in autumn, and Mangold in the spring, extending over 20 acres, in such proportions as the requirements of the stock may dictate. As we are advocating what may be called a five-course rotation, each division will contain 40 acres, thus there are 20 acres more to crop in this division. This should be sown equally with Beans and Peas, which may be succeeded by Wheat following a fallow made after the Rye, Trifolium, and Vetches have been fed off by sheep. The Mangolds should be pulled for food at the homestead, or for feeding sheep in the following spring upon the land. As soon as the Beans and Peas have been harvested the land should be scarified and autumn-fallowed, and the whole 40 acres under preparation for Wheat must be manured at a convenient opportunity. If the season is unfavourable for the dung being laid out artificial manures may be applied—a portion at seed time, and the remainder in the spring. The land where the sheep have been folded on the green crops will, with the autumn fallow succeeding, be well prepared for Wheat without any manure until the spring, when, if requisite, it may be dressed with nitrate of soda. We have thus accounted for two years out of the five by green crops, roots, fallow, and pulse crops in the first year, and Wheat in the second year. The third course should be Lent corn, either Oats or Barley, or both in admixture, called drege. If for Barley the land should be prepared by steam power, and broken up roughly to lie the winter. In the spring the Red Clover seeds will be sown in the Lent corn upon half the lain

—viz., 20 acres. The other half should be sown with Dutch and Alsike Clovers mixed with Timothy Grass seeds, thus completing the fourth course. In the fifth and last course 20 acres may be retained as old lea, and 20 acres sown with Beans and Peas, the latter being sown on the land which was devoted to green crops and fed off by sheep in the first course. This will complete the cropping on a farm where sheep may be kept in summer time. It will be noticed by the home farmer that there will be various opportunities for short fallows under this system, so essential to the successful culture of heavy land. The crops grown under this rotation will be 20 acres of green crops and roots, 40 acres of Beans and Peas, 40 acres of Wheat, 40 acres of Clover and grass, 40 acres of Lent corn, and 20 acres of old lea.

We will next consider a rotation of crops adapted for the strongest land where few if any sheep are kept, and the root and green crops are employed for feeding fattening cattle or sheep in covered yards, or for dairy or store cattle, all roots and green crops being removed from the land. We propose, as before, to take an arable farm of 200 acres, to be cropped under a four-course; steam power, however, being a great necessity in the cultivation. The first course will be prepared by an autumn fallow, and as we have 50 acres to crop in this division 15 acres may be sown with Rye, Trifolium, and Vetches, 15 acres with Mangolds, 15 with Swedes, and 5 acres with early common Turnips. All these crops should be prepared for by autumn cultivation, the green crop seeds being sown in the autumn. The land for root crops must be deeply ploughed to lie during the winter, but in the early spring no ploughing should be required for roots. Sow early, in order to secure the heaviest crops of roots and an early autumn clearance, as all will require to be removed and stored either by a heap in the field or at the homestead for feeding cattle in the winter and spring months. The green crops being removed early will offer no impediment to fallowing the land after, and laying out the manure for Wheat; the land for roots will have been spring-cultivated, and hand-picked to remove grass and weeds, being also horse and hand-hoed in due season, grass and weeds again being forked out, or the land scarified after the removal of the crops. The whole of the root land will then be manured and ploughed for Wheat, or in case of adverse weather the carting of manure may be dispensed with, and artificial manures used instead; after the Wheat has been drilled, and for such land it should be drilled at 12 inches between the lines, giving an opportunity for effectual horse-hoeing in the spring, for in some seasons unless this is done the crop will be greatly depreciated. Thus the first course for fallow crops will have been completed, and also the second course sown with Wheat, each being 50 acres. The third course of 50 acres may be appropriated as follows:—15 acres being sown with Wheat and broad Clover, 15 acres with Dutch and Alsike Clover mixed with Timothy Grass; and 20 acres with Beans and Peas, either together or separately, or the Beans may be mixed with winter Vetches. This completes the third course, which may be in the fourth course followed by Lent corn, or Wheat in part; for 25 acres of this land may, when the season is favourable, be sown with either out of lea, and the remaining 25 acres with Oats or drege in the spring, or in favourable seasons a part may be sown with winter Oats.

In this four-course cropping we provide of green and root crops, 50 acres; of Wheat, 50 acres; of Clover and grass crops and pulse, 50 acres; of Lent corn and Wheat, 50 acres. In practically criticising this rotation of cropping it may be said that the cost of tillage will be too great for any advantageous results; but it should be borne in mind that the heaviest labour is not only done more effectively by steam power than it could be done by animal power, but that the practice sets the horses free to do a large portion of the work which could not be done by steam. One great feature in the rotation will be found in the fallowing, which may be as effectively carried out for all useful and reproductive purposes as the old-fashioned long winter and summer fallow, whereon must be charged rent, tithes, and rates, the labour bill of horses and men for a year, without anything to compensate. The four-course rotation we advise will not only carry out successfully all the objects for which fallowing may be said to be necessary, but that it, under intelligent management, provides an enormous amount of vegetable and green food for cattle, horses, and sheep. This must be considered an important point in the management of the home farm, especially at any period when corn and pulse is selling at a low price. We have now to give the old-fashioned rotation to enable the home farmer to take notice of by comparison with those we have named. It is first year a long fallow, manured; second year, Wheat; third year, Oats or drege; fourth year, Clover and part Beans or Peas. The principal points to be observed in this rotation is an almost entire absence of food adapted for the feeding

of stock, and consequently the loss of profits thereon, with but little manure made to renew the fertility of the land.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—We will suppose that in accordance with our recommendations both the horses and all implements required for harvest work are waiting only the word of command to commence operations. It then becomes a question of how far the home farmer is provided with the machinery necessary for cutting and tying the crops of corn, &c. There is a difference of opinion amongst farmers in some districts as to the carting of Lent corn, such as Barley and Oats, in a loose state or tied into sheaves. Our opinion is that it is best to tie and set up every kind of cereal in shocks, particularly where the reaping and binding machine is employed; because if the corn is quite dry when tied into sheaf, and the shocks are kept properly set up, all the straw and grain cannot be injured even in the most adverse weather. The only disadvantage we have experienced in the practice has been where the Clover and grass seeds were sown in the corn, as if the shocks stand for any lengthened period the young plants will be destroyed. It may be thought that these might be removed on a fine day, but on the return of heavy rains the sheaves removed will suffer seriously, because the portions of the sheaf hitherto sheltered will become exposed. In very high winds, which usually accompany a wet and stormy season, when the stooks are blown down they may be set up again upon fresh ground, but in round shocks to avoid the effects of the wind. The advantage of tying Lent corn is found chiefly in the diminished labour and time required both of horses and men at carting time. We have also found that when sheaved either Barley or Oats may be made into round instead of oblong ricks. We much prefer the former plan, because the butts of the sheaves face the outside, receiving less damage from winter weather, and a round rick needs less thatching and is not so likely to be stripped by high winds.

Hand Labour.—Although in the early districts harvesting has commenced, yet the home farmer should remember that labour will be required in hoeing the young Turnips and in the second hoeing of earlier root crops. This matter cannot be neglected with safety, therefore some men must be employed in the hoeing of roots and similar work during the harvest month. Where labourers are scarce it is a practice to turn most of the horses out to grass during the early part of the harvest before the carting of corn commences, in order that the teammen and boys may be available for harvest work. We object to this plan, because the few days or a week's work for the horses is lost at a time when we have found the labour of the horses of far more consequence than that of the men. The home farmer must now consider that the harvest work is most important, but the sheep and cattle should on no account be neglected. The lambs recently purchased on the grazing farms and stock lambs on the hill farms should be shorn about the middle of this month. The ewes, too, can be leared or dipped to prevent the fly striking. In a season like the present dairy cows require little food besides their pasturage; if, however, the grass should run short the second cutting of Clover becomes valuable for them, instead of risking making it into hay. In harvest time the work of cutting Clover for horses or cattle should be done by a man appointed for the purpose, and employ the odd horse for carting it to farmstead, instead of the teammen being taken for the purpose. The women, where they are encouraged to work, are capable of doing much light work besides that of the harvest field, except where a man and his family undertake the work of cutting corn and pulse by the acre. The method of running pigs over the stubbles after harvest is nearly abolished or fallen into disuse, because under ordinary management the horse-rake leaves little food for pigs, and we often find the difficulty of keeping pigs in the fields intended for them.

METHOD OF TESTING MILK.

THE lactometer, a short tube of large dimensions, weighted at its lower end, and carrying above a slender graduated stem, is the simplest instrument for testing milk, and is far more generally used than any other instrument in Europe as well as in this country. When the milk to be tested is known to be unskimmed, and the temperature of the liquid at the time the test is made is 60° Fahr., the indications obtained by this method are sufficiently reliable for ordinary purposes. The lactometer used by the New York Board of Health is graduated from 20° up to 120°; the 100° corresponds to a specific gravity or density of 1.029, which is taken as the lowest allowable limit for pure unwatered and unskimmed milk; the 114° corresponding to the specific gravity of 1.033, is taken as the highest allowable limit for pure whole milk; the test is made in all cases at 60° Fahr. These limits correspond with those generally adopted elsewhere. There are undoubted cases, however, in which the density of the milk of a single cow has been found to be less than 1.029 at 60°, and it is safe to use this standard of purity only in the case of the mixed milk of several cows, at least three or four, as usually received at a factory; and even then it would be prudent not to take action against a

suspected patron, unless the lactometer indicated a few degrees below 100. It is, we believe, the practice of the New York Board of Health to proceed against a dealer only when his milk indicates 90°.

The skimming of milk cannot be detected by the lactometer; in fact, as is generally known, skimmed milk can be watered so that it will have the density of good unskimmed milk. Any experienced dairyman can tell by the appearance of suspected milk whether it has been much skimmed or not. For the detection of a moderate removal of cream the cream-gauge is a very unsatisfactory test, upon which very little real dependance can be placed. Many methods have been proposed for the approximately accurate determination of fat in milk, which shall not require too much time and manipulation, but nearly all of them have failed to answer the purpose. Marchand's lactobutyrometrical test, a full account of which is given in the report of the Cornell University Experiment Station for 1879-80, has most successfully stood the test of time, although it is not yet all that could be desired. It requires but little apparatus, and the manipulation is easy and short. Such a description of the method as would be of any practical use to our inquiring friend would take up so much of our space, that we must refer him to the report, which, as has been already stated, can be had on application to Professor G. C. Caldwell, Ithaca, N.Y.—(*New York Tribune*.)

PRESERVING EGGS.

THE provident housewife should now be busied with preserving the superfluous eggs of summer against winter scarcity. We believe the recipe long ago given by the Hon. Mrs. Arbuthnot, "*the Henwife*," *par excellence* the best. She wrote: "Once a week I clear my baskets, selecting only perfectly formed eggs; the slightest fracture or imperfection in the shell would cause the failure of a whole batch. I place the eggs carefully in a jar and pour over them lime water, which is made by dissolving quick-lime in the proportion of two shells to four gallons of water. This must stand a day at least till the residue has settled at the bottom of the vessel. The clearer portion is then poured over the eggs so as to cover them. Should the jar not be full fresh eggs are added from time to time, and as the lime water rises it is poured into another jar ready to be filled in like manner. Be careful that the eggs are at least an inch below the surface of the water; place a plate or lid of wood over them to prevent their floating; tie up the jar and label it, stating the date and number of dozens."

PIGEONS—PARTING THE BIRDS—FLYING.

PIGEON FANCIERS must now be thinking of parting their birds—at least, if they have accommodation for doing so. Pigeons which were mated early will by this time have been occupied long enough with the arduous task of rearing successive families. We believe the season has in general been a good one for Pigeons; we certainly have never reared more or stronger birds—a strange contrast to last year, which we found absolutely disastrous to young Pigeons! It is often difficult to know exactly when to part pairs. The hens generally lay again before their last squeakers can feed themselves, and so we are tempted to go on from nest to nest. If we allow this much longer our birds, specially the hens, will not be well through the moult by the showing season. Either the last-laid pairs of eggs must be transferred to common birds, which are stronger and can be allowed to breed as long as they like, or they must be destroyed. The hens should then at once be removed and placed in a house without cocks and without nesting places.

We are glad to see that the world in general, apart from mere Pigeon fanciers, seems now to take considerable interest in Pigeon flying; at least, we judge so from the constant notices in the daily and weekly papers of interesting flights. *The Graphic* of Saturday last states, "On the 25th July a Pigeon started from London at 6 A.M. and arrived at Cologne exactly at 12, thus 'doing' the distance in twelve hours." It is well that the public should be interested in the subject, for in case of national emergencies homing Pigeons might be of the greatest use, as they were during the siege of Paris.—FANCIER.

VARIETIES.

THE POULTRY CLUB.—We understand that a Committee meeting of this Club is to be held to-morrow (August 13th), at the Charing Cross Hotel, at noon.

— BIRD PRESERVATION.—Lord Dartrey has been calling attention to the general disregard shown in Ireland to the Acts for the

preservation of birds and sea-fowl. The police are apparently too much occupied with the preservation of human life to think of that of the unfortunate birds.

— DUCLAIR DUCKS.—We learn from a letter to a contemporary that Miss Mary Arnold has been searching in France for Duclair Ducks. We are much interested in any additions to our aquatic domestic birds, and shall be glad to hear the result of the search, still more to see the birds in the exhibition pen.

— WE have received the schedules of the poultry shows to be held at Winslow on September 16th, and at Worcester on September 18th and 20th. The former is that of the Royal and Central Bucks Agricultural Association, which has generally been held at Aylesbury. The classes are much the same as usual, and for birds of any age. The classification of the Worcester Show is on the whole good, though we much regret to see but one class for all varieties of Dorkings. It is confined to chickens of the year.

— HEAVY RAINFALL.—From Leicester we learn that the heavy rainfall of Saturday night and Sunday morning has caused the River Soar to overflow its banks and submerge large tracts of land. At Sileby, Barrow, and Cotes, and the neighbourhood of Loughborough the waters are out to a serious extent; in some instances the roads are 2 feet under water. The meadows near Leicester present a deplorable aspect, sheets of water extending for miles, and in many instances the crops have been destroyed. A considerable quantity of hay in process of making has been washed away.

— WHEAT IN AMERICA.—The *Prairie Farmer* says—"The capacity of this country for the production of Wheat seems to be almost illimitable. Corn does not thrive well at an elevation greater than that of 5000 feet, while Wheat can be raised between 2000 and 3000 feet higher. In the far west there is an area of two hundred million acres of land where Wheat will grow and corn will not. The capacity of the Canadian North-west for Wheat production has been previously adverted to in these columns. It is believed that in this territory alone all the bread needed by the world can be produced. The chief obstacle to this last-mentioned consummation is the distance of that region from the principal markets; but, as mentioned in a previous number, the increase of railway facilities and the already existing system of water communication are on the way to furnish an early solution of the problem."

— FUMIGATION FOR GAPES.—Entomologists always prescribe as a cure for gapes in chickens to remove the worms from their windpipes with a feather or horse hair. The truth is, not one person in a hundred has the requisite skill to perform this nice surgical operation; hence the remedy, though often repeated, is valueless. A much better way is to kill the parasites with tobacco smoke. They then let go their hold on the mucous membrane of the windpipe, which stops the spasms and relieves the chicken at once. They are afterward probably thrown out, or at least never give any further trouble. The remedy is safe and sure. We have never failed in a single instance in this treatment of chickens, although in many instances they were in the last stages, and hardly able to walk. The smoke may be blown into the nostrils through a pipe by enclosing the head in a little bag, or where there are a number of chickens affected they may be put in a basket and covered with a cloth, and then placed over an iron or earthen vessel, in which the tobacco may be burned, the smoke being forced into the basket by a cloth spread around. The chickens should be examined every few seconds, and whenever one becomes stupid it should be taken out and laid on the ground, where it will soon recover.—(*New York Tribune*.)

— MANUFACTURE OF FOREIGN CHEESES.—A few of the continental cheeses have been on a small scale imitated in this country; it is obvious, however, that they will not be extensively produced until the taste of the people has been so educated as to create an equivalent demand for them. Such education is, however, no doubt going on. The Gorgonzola, a famous Italian cheese, in some respects resembling the Stilton, has been very successfully imitated in Leicestershire, and there can be no doubt that, with the exception of the Roquefort, all the more worthy and popular of the continental kinds of cheese can be successfully produced in England. Whether

or not it will be profitable to produce them is a problem whose solution we leave to time. Some of our well-known authorities are advocating the production of soft cheeses in the place of a portion of the hard ones peculiar to this country, and it is to be hoped that an opening for some of the better kinds will be provided. Made for early consumption, the returns will be quicker, and a new element of variety will be introduced into the dairying of these islands.—(*"Dairy Farming," by Professor Sheldon.*)

— **HARVEST PROSPECTS IN THE MIDLANDS.**—Great delay has been experienced in gathering in the hay harvest in Warwickshire owing to the wet weather, and in many instances the crops have been so damaged that they will scarcely repay the increased labour expended on them. Wheat has been thrown back considerably by the weather, and at present it is hard to say what kind of yield it will be. Barley is about an average. Oats are better than last year, and promise well. Beans are likewise in better condition, and above the average. The harvest will be a late one. Potatoes are a good yield, but in some instances the disease has appeared, not, however, to a great extent. The root crops are looking well, but plenty of weeds are to be found. A few weeks' fine weather would make a wonderful difference to harvest prospects in this district.

— **REARING TURKEYS.**—Much of the alleged delicacy of young Turkeys is no doubt owing to the degeneracy of the strain, the produce of an American cross being always found much more hardy. It is, however, quite true that during the earlier weeks, and before the young birds "shoot the red," as it is expressly called, or develop the red carunculated protuberances about the neck and throat, they are peculiarly susceptible to wet, so that even one good wetting will perceptibly thin a large brood. After that period is passed, however, they become daily more hardy, so that they will roost in trees during winter if permitted without any injury, unless unusually severe frost may cause frost-bitten toes. The period of danger being thus limited, it is well worth while to take special care while it lasts. Special and ample shelter should therefore be provided, and if the hens are at liberty they should be driven under it on the approach of a shower; by which means, if well fed, the dangers of infancy may be warded off. For a period of one to three weeks—depending on the weather—the hen should always be confined, the Turkey chicks being, however, allowed to run out on the grass during dry days. Such management, with plenty of good meal as food, will bring the chicks on with little difficulty. Many farmers feed only on grain after a week or two, but on such diet the young birds never grow large, and rarely show good constitutions. There is another thing to be remarked: Many careful observers have recorded that, when given the option, Turkeys seem to prefer the leaves of the Dandelion to any other green food, and it has been found that such leaves liberally given conduce greatly to the health and vigour of the broods. The well-known medicinal properties of this plant (employed in medicine under the name of taraxacum) both as a tonic and alterative, make these effects easily understood; and it is therefore well worth while to encourage the growth of the Dandelion wherever Turkeys are reared. This object, as gardeners well know, is only too easily attained in most places; but even if necessary to scatter a few heads of seed over small patches of ground, it will pay well to do so. In default of the Dandelion, Lettuce and Onions chopped fine form the best substitute. Dryness and cleanliness are, however, the chief requisites in Turkey-rearing so far as prevention of deaths is concerned.—(*Cassell's Illustrated Book of Poultry.*)

EXPERIENCES WITH COMB FOUNDATION.

THE report which Mr. Procter gives is very interesting and valuable, but it is certainly puzzling to read the very different accounts which are given by persons who try these comb foundations. I gave mine honestly some time ago on the invitation given in our Journal, nor can I write a word beyond my own experience. It is not so promising as I could wish it, for it is evident to the simplest understanding that if Mr. Procter's experience were general we bee-keepers would find ourselves in a most favourable condition for the successful management of our apiaries. Why is it that such men as Mr. Cheshire and even Mr. Raitt have had to try, and are still trying, all sorts of experiments to strengthen

comb foundation? They, like myself, have been disappointed again and again. The combs we have used have "sagged" and continue to do so. Crooked combs, curling corners, breakdowns have with the majority (so far as reports have come in) occurred again and again, and hence at the cost of much trouble and labour and expense recourse has been had to every sort of device for remedying the evil by the adoption of strengthening materials of every imaginable kind. It can be no fancied difficulty which has given rise to all this inquiry and trouble. The fact remains, that while some apiarians like Mr. Procter have been greatly successful, others, "the majority," among whom I must reckon myself, have been met by difficulty and disappointment. It may be—it must be—that there is something in the mode of manipulation or the character of the comb foundation itself, or some other treatment still a secret to the apiarian world, which leads to the success we are told of. This we want to get at, and he would be a real benefactor who should plainly and minutely describe how after seven years of comparative failure (see page 107) he at last attained that perfect success which is described. Are we all mere blunderers? It is very certain there can be no confidence or more general adoption of comb foundation till our practical difficulties are removed. We are not throwing out mere ideas, but stating facts within our experience.—B. & W.

EXTRAORDINARY SWARMING.

MR. A. PETTIGREW has forwarded us the following letter accompanied by his reply:—"Mr. J. Greatorex, farmer of Stretton, a little village close to Burton, started this year with one stock very well up in bees. Swarm No. 1 came May 20th, No. 2 (or cast) June 3rd. No. 1 swarmed June 7th, and cast July 3rd, while the swarm which came from No. 1 (June 7th) itself threw off another July 2nd, which, however, returned to the hive. He has thus increased his one stock to five, and would have had six had not one swarm returned.—CHARLES YOUNG."

[Though bees swarm readily this year everywhere, the above-mentioned instance of a swarm from a virgin hive probably stands alone, and should be remembered. As such superabundant swarming weakens hives we trust Mr. Greatorex will feed all his five hives into good stocks and carry them well through winter.—A. P.]

REVIEW OF BOOK.

The Bee-keepers' Manual, by the late Henry Taylor. Seventh Edition. By ALFRED WATTS. London: Groombridge and Sons.

THE name of Henry Taylor was at one time very familiar among apiarians, and the "Bee-keepers' Manual," of which he published six editions in his lifetime, was regarded as the most authoritative guide to those who were about to enter upon the pursuit of bee-keeping. Many changes have taken place, and great progress has been made in apiarian science since Mr. Taylor wrote, and it was necessary for a work of this kind if it was to keep pace with the times, and to be of good service as an instructor, that it should be very much amplified. The construction of the work is the same as it came from Mr. Taylor's hands so far as the subject is treated under the heads of Summer, Autumn, Winter, and Spring Management, and this is a method we like; but in addition to this the whole subject of bee management has been gone into upon modern principles, and all the various forms of wooden and straw hives together with all modern apiarian apparatus are fully treated upon. We consider this edition of Taylor, under the editorship of Mr. Watts, as good a manual for the bee-keeper as is to be found in the language.

BRITISH BEE-KEEPERS' ASSOCIATION'S SHOW.

SECOND NOTICE.

ENGLISH comb foundation brought but two entries, which appeared in the catalogue; Messrs. Raitt and Neighbour, the former with sheets of great finish, being placed first. Mr. Abbott staged flat-bottomed thick foundations, the cell walls of which on the opposite sides of the sheet do not stand in that beautiful relation to one another which they occupy in natural comb, and which has been followed in every other specimen of foundation we have seen. The cottagers' classes for honey were all good; Messrs. Skinner, Walton, Freeman, and Sells were well to the front. The American thin flat-bottom foundation for supers exhibited by Messrs. Newman & Son of Chicago was of wonderful regularity, and in sheets 36 inches by 16 inches.

With extractors Mr. Cowan was again to the front, winning with a machine which perfects his invention of last year. The combs are reversed automatically, and the gearing which effects this is as simple as it is ingenious. The driving pinion and the pinions which reverse

the sides of the combs stand respectively in the centre and at the ends of a long narrow box, which forms part of the revolving cage. A continuous sliding rack fits into the teeth of these three pinions. When the driving pinion has sent this rack as far as the end of the box will permit it to travel the combs are set with one face outwards, but by reversing the turning of the handle the pinion moves the rack towards the other end of the box, and so by playing on the comb pinions gives a half revolution to the comb cages. The mechanism is so contrived that it can be very easily slipped to pieces for cleaning, while the gearing cannot be touched by the honey, which a strainer permits to be bottled direct from the machine. Mr. Walton exhibited a less pretentious but at the same time an admirable low-priced extractor, which was placed second. The spindle is passed through the fixed part of the can cover. On the end of the former is a wheel about 2½ inches in diameter, having a thick indiarubber band for its tire. Against this comes the similar tire of the driving wheel, the two simply slightly pressing each other. The result is a very smooth and noiseless movement, which does its work excellently. With Mr. Cowan's extractor for our *bourgeoisie*, Mr. Walton's for those with narrower purses, and Mr. Abbott's Little Wonder at less than half the price of the latter of these two for those who do not mind for economy's sake hard work and some inconvenience, we think but little remains to be done, but perhaps Mr. Cowan may show us next year that we have been mistaken. The judging of the beeswax puzzled us. It may be that there are virtues in wax which we have never discovered.

The New Invention Class brought out the unprecedented number of twenty-four entries, but some of these were hardly entitled to a position in the class at all—for example, Dr. Pine's lotion and bee veil, but yet enough remained to show a wonderfully increased interest in apicultural matters. Mr. Cheshire received the silver medal for his new method of fixing foundations by wires, with which the readers of this Journal are already familiar. He was also commended for a divisional feeder, of which the Judges report that it displayed great ingenuity and is very well fitted for feeding inside the hive without interfering with the colony of bees; but its cost must preclude it from use except in those cases where an amateur considers expense of little consequence. Mr. Hooker exhibited an ingenious and useful way of setting foundation in frames. A saw-cut runs through the top bar. This is splayed open by a screwdriver or thick nail. A little double-pointed tool is stuck into the two sides of the top bar as they are held open. The screwdriver being withdrawn admits of the insertion of the edge of the wax sheet. The tool is removed, the wood springs back, and the sheet is firmly held. Mr. Cowan showed a very convenient swarm-catcher which, placed at the end of a pole, can be closed at once by simply pulling a string after securing the fugitives. Mr. Hunt introduced the Hampshire bee feeder—a tin can with a glass tube running through the bottom of it. Into this a woollen plug fits, permitting the syrup to drip out so slowly that the bees are sure to take all that is given. Mrs. Leigh Spencer's bee skirt for ladies' wear is worth the attention of all whom it may concern. It is a sort of bag for the skirt, with strings or elastics for the ankles. Mr. Parsons exhibits waxed paper guides, but these have long been tested and found wanting. When bees are busy they adopt them and build combs from them, but in idle times one finds a fibre and the teasing-out begins, which brings perhaps a whole comb to destruction. Mr. Parsons' model of a slinger is wrong in principle. Much dead weight must be driven in addition to all the honey slung, and the comb when at the bottom of the circle it describes has to sustain a strain greater by twice its own weight than it bears when at its highest point. If the latter force is sufficient the former must be excessive.

The remaining classes call for little remark, except that exhibiting diagrams, now perfectly well known and in which Abbott Bros. deal, can hardly be thought meritorious enough to entitle them to a bronze medal without reducing somewhat the estimation which we should suppose the Association would like to see attached to its honours. In conclusion a study of the hive classes shows clearly that exhibitors generally are striving after greater facility in moving frames, and the tin or zinc runner and distance pin are now quite the rule. Elasticity is found in every winning hive. It would perhaps put it more strongly to say that there cannot be a good hive without it. The value of double walls is no longer overlooked, while chaff covers are used for wintering. Results speak yet more eloquently of progress, the comb honey of this Exhibition being finished in appearance and marketable in form, while the extracted by contrast brings to mind some of the dark cloudy honey which entered the prize list in former years, but at which no one would now look. The Association has spread much of the light of which this is the evidence, and it ought in consequence to receive our encouragement and support.

OUR LETTER BOX.

Chicken Suffering from Roup (*Mr. Wardle*).—The chicken you sent was affected with this disease, which is marked by an offensive discharge from the nostrils, froth in the corners of the eyes, and their lids swollen. It is generally caused by exposure to excessive wet and cold, and is contagious. Wash the head daily with tepid water. Give to each bird daily one grain of sulphate of copper mixed in oatmeal mashed with ale, and plenty of green food. Separate the diseased fowls from the others. We submitted the chicken to careful treatment, but it has since died.

Ducks Unhealthy (*J. R. C.*).—Your account of the Duck's malady is very extraordinary; we have never known any suffer in a similar manner, and are

inclined to think they must eat some poisonous water-weed. We advise you at once to get a competent person to make a post-mortem examination of one. If too closely confined Ducks will die of liver complaint, but the symptoms are hardly such as you describe.

Dorking Cock Wheezing (*A. G.*).—The Dorking cock is suffering from cold or incipient roup. In either case the treatment would be the same. Give castor oil freely, a tablespoonful at a dose, and every other day. Twice or three times per day for a week feed the bird on stale bread steeped in strong ale. Keep him in a dry place, and let him have sun if possible.

Transferring Brood (*F. G., Exeter*).—Transfer the brood to the frames in the usual way. This will only occupy three or four of them at most, and give foundation in the remainder. Put one or two sheets of foundation between the brood combs according to the strength of the bees. By continually moving the old combs to the outside of the cluster the eggs laid by the queen will all be placed in the foundation. When all the brood has hatched from the old combs remove them and supply foundation in their place. Feed of course until wintering condition is reached.

Driving Bees (*W. B. W.*).—Your bees may be driven from their hives by anybody who has courage enough to blow some smoke from fustian rags into their hives amongst them, turn the hives on the crowns (upside down) and place empty hives on them month to month, and roll tablecloths round the junctions to keep the bees in. When this is done commence at once to drum on the bottom hives with both hands, or two books, or two pieces of wood, and continue this work for fifteen or twenty minutes. This drumming disturbs the bees so much that they run up into the empty hives.

Rats (*Somerset*).—Coal tar smeared about the entrances of their holes and poured into the drains they frequent may drive them away. Apply to the gas-works for the tar.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 1st.—Rain in early morning, fair day, but much cloud and little sunshine.
- 2nd.—Dull morning, rain from 10.30 A.M. till 1 P.M., fine in afternoon with bright sun, showers in evening.
- 3rd.—Cool but very bright morning, fine day, overcast at intervals.
- 4th.—Moderately fine day, but not much sunshine.
- 5th.—Fine bright morning, afternoon and evening hazy, close, and oppressive.
- 6th.—Dull morning with spots of rain, shower at 1 P.M., dull cloudy afternoon and evening.
- 7th.—Fine and bright early, cloudy morning, wet and windy afternoon and evening, heavy westerly gale in night; steady and rapid fall of the barometer all day, steady and rapid rise all night.

Temperature rather lower than that of last week, though there was so much less rain, rather low also for the time of year, but remarkably like that of the first week of August last year.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 11.

TRADE is now very quiet in our market, and all classes of goods have experienced a fall, large quantities of fruit reaching us from the continent.

ROSES FROM CUTTINGS.

NEVER, perhaps, has the value of dwarf Roses been more apparent than during the present season. In the southern counties and favourable localities standards have passed the winter with comparatively little injury, but over a vast extent of country, and in the north especially, most of the trees are dead, and the survivors present a miserable appearance. In a majority of gardens only the dwarfs are healthy, and these in not a few instances are growing luxuriantly. These plants may have been worked on the Manetti, seedling Briar, or Briar cutting stocks, but most of them are practically on their own roots, and probably would have been equally healthy had they been grown from cuttings instead of having been budded or grafted. It is certain that nearly all Roses on their own roots grow freely and produce fine blooms. A few may not do so, but they are few indeed, and can either be dispensed with or given the peculiar treatment they require.

It is a little strange that own-root Roses are not raised in any large numbers in nurseries. Manetti cuttings are struck by the million, and Briar cuttings by thousands, while seedling Briars are raised in very large quantities; but Rose growth is left on the trees until the spring, and the shoots that, if taken at the right time would have made cuttings innumerable, are consigned to the flames. Nothing better can be done with them at that time, for not one in a thousand will strike if inserted at pruning time, while, on the contrary, few will fail if properly chosen and carefully inserted from now until November.

The best wood for cuttings is that which is short-jointed and rather firm. Sappy luxuriant shoots will not do, and weak stubby growths are not desirable. The latter may emit roots very well, but they are long in making good plants.

Seven years ago I inserted in three short rows a dozen cuttings each of the Manetti, the Briar, and John Hopper Rose. All the Manettis grew, all the John Hoppers, and nine of the Briars. In due time the stocks were budded, but the John Hoppers took the lead and kept it, and are the best bushes now. This is the only fair way to test own-root Roses against worked plants. I have seen so-called trials of the different types conducted in this manner—cuttings of Roses have been planted at the same time that buds of the same Roses have been inserted in other stocks. Under these conditions those budded have made strong plants the soonest, and their superiority has been pointed out over the others; but it was forgotten that the budded plants had a clear year's start. Let

the plan above mentioned—namely, cuttings of stocks for budding, and of Roses for growing and blooming, be inserted at the same time, and it will be found that the plan of working the Roses on other stocks does not possess such striking advantages as is popularly supposed.

Rose cuttings, I have said, may be inserted from now until November. The present time is preferable, especially when only a few scores or hundreds are required; but if thousands are needed it is more profitable to insert them in the autumn, or when the Manetti or Briar cuttings are planted. It may very naturally be remarked, that if August is the best time for inserting ten Rose cuttings, it is also the best for inserting ten thousand. That is the logical view of the case, but gardening practice cannot always be successfully conducted by rules of logic.

An important element of success in striking Rose cuttings in summer is keeping them perfectly fresh—*i.e.*, they must be just as fresh when placed in the soil as when cut from the trees; in fact, the work cannot be done too quickly. If once the cuttings shrivel—and they shrivel rapidly—few will grow; but if quite fresh, well selected, and rightly inserted, few will fail. This essential of perfect freshness can be maintained when the number of cuttings is limited, but cannot at any rate without some trouble and difficulty when they amount to thousands, and those who have to be entrusted with the work cannot be depended on for exercising the care that is really requisite when they cannot see the necessity for it.

As above mentioned, rather firm short-jointed wood is the best for cuttings.—Wood containing much pith on the one hand, or very hard and wiry in appearance on the other, should be eschewed. Those shoots that have produced blooms make excellent cuttings, and the lower portions of moderately strong shoots strike freely. It is not necessary to take them off with a "heel," though such "slips" will grow. The cuttings may be about 6 inches in length, a little more or less not being material. They should be cut smoothly across close under a joint with a very sharp knife, all the leaves being removed, but not the buds, except the top leaf, or if very short-jointed the top pair. The cuttings should be inserted quite up to these top leaves, or in other words 5 inches of their length being in the soil and 1 inch above it. The soil is preferably rather light in texture, made fine by careful digging, but trodden rather firmly before planting the cuttings. They may either be placed in trenches, prepared as if for planting Box edging, or be inserted with the dibber, the worker standing on a board and planting by its edge, as if pricking-off Cabbage plants. I like this plan the best. If the Rose cuttings are placed in trenches some sand should be put round them before levelling-in the soil and firming it. If they are dibbed-in, the surface should be covered half an inch thick with rough sand or gritty road sweepings. A blunt dibber should be used, which forces the sand downwards, on which each cutting must rest firmly, and the soil must be made firm especially at the base of the cuttings. Thousands of cuttings of all kinds are spoiled annually by simply hanging them, the soil at the base being loose, while near the surface it is patted round the cuttings with some care. The very reverse of this should occur both when inserting cuttings and young plants of all kinds.

Rose cuttings inserted now are the least trouble if a partially shaded border can be afforded for them. They should be placed about 4 inches apart in rows a foot asunder, there to

remain until the plants are large enough for removal, as many of them will be the following autumn, the others being then replanted at wide intervals to make further growth. If not in a shaded border and the sun is bright, they should be shaded with mats and syringed frequently to keep the foliage fresh, as the longer this is retained the sooner will roots be emitted. Any shading that is employed must be removed at night, so that the cuttings can have the benefit of the night dews. I have struck many hundreds of Rose cuttings according to the plan indicated, and if others attempt the same practice and fail it will be because of some error in choosing the cuttings or fault in management. Those having frames at their disposal can strike the cuttings more quickly, but the lights should be drawn off during fine nights.

Autumn propagation is more simple, and when large quantities are required more convenient, but as a rule I have found it less certain. As soon as the leaves change and can be shaken off, the cuttings may be made and inserted in trenches as above described. Sometimes, however, the leaves cannot be shaken off before December. In that case they may be cut off about the end of October or early November, for by that time the foliage has done all that is needed for the wood; and if the evaporating surfaces—the leaves, are removed, the cuttings may be prepared in bundles of hundreds, and with very little care no shrivelling will occur. They do not need to be inserted in a shaded border, but any open position will be more suitable. Cuttings divested of foliage and inserted in the autumn may with advantage be an inch or two longer than those planted in summer, but only an inch of each cutting should be above ground in both cases.

Manetti and Briar cuttings for stocks are made and inserted much in the same manner as soon as possible after the leaves have fallen. Yet a most important difference must be observed. In making Rose cuttings none of the buds require to be removed, as these push from below the surface and make fine growths. No winter in England can kill Roses thus prepared. But cuttings for stocks must have all the buds removed from the portion inserted in the soil with scrupulous care, or "suckers" will spring up continually, to the great annoyance of the cultivator and ruin of the plants. Stock cuttings are made about a foot long, inserted to a depth of 5 or 6 inches, the soil being drawn or banked up, the remainder within an inch of the top. They are thus in ridges, which before budding are levelled down; the bark then runs freely, the buds are inserted near the root, and the plants properly planted become in due time own-root Roses. This, however, is nurserymen's work, and no one can do it so well as they can. It is the most convenient for raising plants by the million, and millions of splendid plants are so raised annually. I write not for these skilled professionals who "know their book" better than I do, and who may be depended on for supplying satisfactory plants; but my remarks are intended for those amateurs who have, the Editors inform me, desired some plain instructions that will aid them in indulging in the pleasure of striking a few Roses, not with the object of growing exhibition blooms, but for producing flowers, the work of their own hands, for rendering their gardens gay in summer and their rooms sweet. Although work presses on all sides I cheerfully comply in the furtherance of an object so laudable and desirable. —A NORTHERN GARDENER.

PRUNING PEACH TREES.

MORE than once the importance of pruning Peach and Nectarine trees immediately after the crops have been gathered has been adverted to in the pages of the *Journal of Horticulture*. The practice, however, is far from general, and trees in many gardens remain crowded with growth that is absolutely inimical to health and fruitfulness, thinning not being done until the leaves have fallen. I am referring now more particularly to trees grown under glass. At the present moment there are hundreds of Peach trellises densely covered with wood and foliage that ought to be at once carefully removed. To permit the shoots that have borne fruit to remain on the trees simply for the purpose of being cut out in winter, either betrays a want of thought on the part of the cultivator, or the want of time to do that which he must know ought to be done promptly.

Overcrowding of the growths of fruit trees of all kinds is one

of the commonest errors committed in gardening, and it is especially apparent in the training of Peach trees. Few will dispute the value of hard, brown, short-jointed wood thickly studded with triple buds for increasing a full crop of fine Peaches and Nectarines. It is a mere accident if such wood is produced when the trees are crowded with foliage throughout the summer, the shoots being trained to the trellis from 2 to 3 inches apart and covered with two or three layers of leaves. How can the sun act on that wood to render it fertile, and the syringe be applied to the foliage to cleanse it from red spider?

It is as easy at the present time as during the resting period of the trees to determine which portions can be advantageously removed and which retained on those trees from which the fruit has been gathered. If one-half, or in some cases nearly two-thirds, of the growth were cut away now, that remaining would be in a greatly improved condition at the end of the season, and a more certain crop and better fruit would follow another year.

After much experience in Peach culture, and an intimate acquaintance with both failure and success, I urge strenuously the importance of making an intelligent selection now of those growths that must be depended on for next year's crop, and to give these shoots every advantage by the removal of others that have done their duty, for to permit them to remain to be cut out in winter is needlessly exhausting the trees, and a sure mode of impairing their fruitfulness. The trees should be so thinned now that the sun can shine on every leaf; and if these leaves are kept clean and healthy, as they easily may be, wood essentially fruitful in character will certainly be produced, and little winter pruning will be needed.—AN OLD GROWER.

LAXTON'S NEW PEAS.

AT sowing time Mr. Laxton kindly sent me small packets of seed of his three best new seedling Peas; and as one of them, John Bull, was figured with accompanying remarks on page 137, I propose giving my experience with two of those received somewhat earlier than usual.

Mr. Laxton is undeniably a great authority on all matters pertaining to Peas, and on this account I was prepared to find John Bull, from the brief description received with it, what it really is, "the king of Peas." It is very sturdy and branching in habit, very prolific; and the pods, though not of sensational size, are large, and like another of Mr. Laxton's excellent varieties, The Marvel, are literally hard packed with peas. It is a main crop variety, about 3 feet in height, and must eventually become one of the best of market sorts. The latter remark is often made about other varieties, simply because the pods are of great size, and the quality perhaps fairly good, no regard being paid to the heights of the respective varieties, and we thus see a variety recommended which grows 6 feet in height. The fact that stakes are not used by the market growers, and that thick pods cannot be sold, are apparently forgotten.

Another variety which I will allude to is aptly named Minimum, which, according to my experience, is a real gem for early work, and unequalled for cultivation either in boxes or pots. In habit it is very dwarf, growing to about 10 inches in height, and so very branching that for the future it will be sown very thinly. The pods are freely produced, are about 2 inches in length, and the very sweet peas are so closely packed in them that they flatten each other in a manner resembling Indian Corn. At a later and more seasonable date I shall refer to the culture of this variety in some remarks on growing early Peas generally.—W. IGGULDEN.

THE *Journal of Horticulture* has lately become famous amongst the profession for the faithfulness of its illustrations, but in my opinion the likeness of John Bull Pea at page 137 is underdone, as the woodcut neither gives the true size nor beauty of it. "Thirteen peas in a pod," however, conveys more idea of its productiveness, and its other qualities cannot be overrated, as it is one of the most wonderful Peas ever introduced. In the spring of this year we were fortunate enough to have twelve seeds of it sent to us, and the produce of these gladdens our heart every time we enter the garden.—A KITCHEN GARDENER.

EUCOMIS PUNCTATA.—A lady from Sligo who has this interesting and too rare plant now flowering finely sends me the following description that would seem to commend it to the notice of your readers:—"I have it now beautifully blooming in my morning room, which it scents most fragrantly. It comes into flower about this time, and remains for the better part of six weeks, the admiration of every visitor. The colour is waxy white, and the florets are closely set on a central spike, not unlike a tall Hyacinth. After measuring this spike, which is

unusually healthy, I find it 2½ feet high, and clothed almost throughout. It is almost hardy—certainly as hardy as *Salvia patens*, and merely requires some protection in winter. The bulbs are, I believe, very cheap.”—W. J. M. *Clonmel*.

STOCKS FOR SPRING FLOWERING.

WHILE fully agreeing with “R. P. B.” on page 138, as to the value of East Lothian Stocks for an early spring, and also a late summer display, I cannot think that plants raised from seed sown now will make satisfactory flowering plants next spring. I have grown these Stocks for many years, and have succeeded best with them when the seed has been sown in rich soil in the open ground about the last week in May or first in June. Plants from this sowing commence flowering in October, and continue improving throughout the winter, attaining the zenith of their beauty about March or April. Dense bushes 2 feet high and as much in diameter, covered with large double pure white flowers during the winter and early spring months, cannot easily be surpassed for decorative purposes. The scarlets are equally fine, but the whites are more appreciated. I have sown seed early in July, and had small attractive plants the following April; but when it has been sown later than this the plants have not been strong and flowered well until the summer.

Your correspondent fails to convey to my mind what he had in his own when writing. He says, “Young plants to flower next spring are now in 4-inch pots, but it may not be too late to sow the seed in the south of England.” This clearly implies that they may not be too late for spring flowering; but he then goes on to say that having been transplanted at the foot of a wall “they may remain there to flower or be transplanted in March.” This implies that they are intended for summer flowering. “R. P. B.” is usually commendably explicit, but in this case his remarks appear to require a little explanation to render them intelligible. I can grow the Stocks very well, but cannot understand the instructions referred to, and if they are puzzling to one it is conceivable that they will be to others of possibly less experience.

If I were asked how to proceed now to have Stocks for flowering next spring I should reply—Sow at once, without a day’s unnecessary delay, seeds of the London Intermediate variety. It is not so fine perhaps, and certainly not so continuous and long-lasting as the East Lothian; but it is quicker, and when well grown beautiful and sweet. Plants for early blooming are ready for pricking off, and when sowing thus rather late there is no time to lose by checks in transplanting. A few seeds should therefore be sown very thinly in small well-drained pots of rich turfy soil. The seedlings can be thinned, leaving about three in each pot, and as soon as the plants are fairly growing, with the roots just coiling round the pots, shift them into pots a size or two larger, making the soil very firm. The small pots must be very clean inside, well washed and dried before they are used, or the roots will adhere to them, and the plants cannot be shifted without injury. The seed pots should be plunged in ashes in a frame, but the lights should be drawn off during all favourable weather both by day and night. For many purposes one plant in each pot is preferable to three, but in that case the seed should be sown earlier, and a greater number of pots must be provided, for it cannot be expected that every plant will produce double flowers; but there are sure to be one or two doubles in every pot of three plants. Well-grown plants of these Stocks, even if small, are extremely valuable for various decorative purposes early in the season. They can be wintered in pits or near the glass in a light greenhouse.

Brompton Stocks are fine for pots or beds; indeed, grand when they produce spikes 2 feet long and flowers 3 inches in diameter. There is just time for sowing the seed. Sow it thinly, and treat the plants as recommended by “R. P. B.” for East Lothians. —A SOUTHERNER.

SCALDED GRAPES.

WITHOUT entering into any controversy with your correspondents regarding their respective opinions of scalding or other of the difficulties that surround Grape-growing, I shall just give a little of my experience that may be as useful to your readers, and I may state that this experience is with nearly two hundred Vines and with over twenty varieties. Last season, from a young cane that I had brought up in order to cut out the old one that had broken badly, I had several promising bunches up to the scalding period, when they were scalded so very much more than the others in the house that my attention was especially drawn towards them, and when, as usual with all such difficulties, I at once attempted to ascertain the cause. Air being the remedy frequently recommended I was the more interested, seeing that

the Vine was growing close to a spout that brought the water into the cistern, and this hole being constantly open these particular bunches secured more air than any others in the house. The nights being cold the temperature occasionally with them would be from a little over 50° to close up to 90°. This end of my vinery, by the aid of a flue, being about a fortnight earlier than the other end, and where the principal of my Lady Downe’s were, I decided to shut up close at nights, also aiding by fire, and the result was very few scalded Grapes. My conclusion then was, with old Vines (with young canes the difficulty is greater) by keeping the temperature at night at 70°, and by day not exceeding 85°, during this period of the Grapes’ growth, damage from scalding could be avoided. During this period it is not desirable that any Grape should be subject to extreme temperatures, but, undoubtedly, Lady Downe’s stands extremes the worst. This year I purposely allowed the air from the hole to act on the bunches as the year previously, but with more attention, as I had no idea of sacrificing my Grapes; but in spite of my closer observations, the scalding stole a march, and the result again is fully two-thirds of the berries are gone.

The result of well-ripened wood is similar in result to breeding from healthy stock—good results; and in badly ripened wood I am thoroughly convinced we have the forerunner of shy-setting, stoneless berries, shanked berries, and also scalded berries. From ill-ripened wood we secure ill-constituted Grapes, and such Grapes are much more than usually subject to all the ills that Grapes are subject to. Ripen the wood, and you may set Muscats at 50° and afterwards grow them to perfection; but if the wood be ill-ripened, then you may bring an army to your aid and all the aid will fail. Showing that ripeness of wood has to do with scalding, or chilling if you like, those with Lady Downe’s at stages before their canes have reached the top of the house will have noticed that the scalding is worst in the bunches from last year’s wood, and especially so over cisterns, or in any other situation where the wood had the least chance of ripening.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street*.

P.S.—Some of your readers may be interested to know the state of my vineries this year. If so, I am glad to inform them that I am proud of them. I have 1600 bunches of fine Grapes.

NEW ROSES AT CHESHUNT.

SEEING is believing, and something more. Seeing Roses in the row growing is a very different thing from seeing them in the box. Impressed with this persuasion I have been glad of an opportunity to pay another visit to Cheshunt; and though not fortunate enough to find there my friend Mr. George Paul, yet I fared well under the guidance of the experienced foreman Mr. Gater. August 12th is a little late under ordinary circumstances, but circumstances of late years have not been ordinary, and the Roses seem hardly to know when to begin blooming and when to stop. The three or four harvest days which are cheering the country had woke up the Roses also, so that I saw still some very excellent blooms, especially of the Marquis of Salisbury, with which I was perfectly astonished. Such size and substance and yet perfect shape I have rarely known together. Several might be described as three *Senateur Vaisse* rolled into one, having all the excellence of that old favourite with a vast advance upon it in magnitude. I saw many plants of Mrs. Laxton, evidently a first-class Rose, and Charles Darwin also in great perfection. This latter, however, seems strangely susceptible to mildew.

Among the ladies, or rather gentlemen, not yet out a very striking Rose is in preparation, after the manner of Dupuy Jamain, but larger and very robust, and which I hear is to bear the name of the justly popular President of the Reigate Rose Association. Messrs. Paul & Son have already a very excellent R. N. G. Baker. The George Baker that is to come will certainly not be less acceptable in the Surrey Rose gardens. I saw a single bloom of a Rose of very great promise, if all worked are like the seedling. It is not yet named, but is of strong growth and of a much paler pink than the generality of the deep dark Roses of Cheshunt. I also saw a large pure white Rose, several rows of it, apparently even whiter and of more substance than Mabel Morrison which was growing near to it. This latter is a Cheshunt sport from Baronne de Rothschild.

The Bennett Roses were also very interesting. For the first time I looked upon rows of them. There were also many in pots. These Hybrid Teas have sprung this year at a bound into an important class. They have evidently great substance—almost too much for a wet season, and great beauty of bud. Pearl, Viscountess Falmouth, Beauty of Stapleford, and Michael Saunders were those I most admired. Duchess of Connaught is very beautiful, but too like La France. Except for the wood I hardly see how they are

to be distinguished. The constant rains had prevented these looking their best. One other Rose I was struck with—Egeria, said to be an enlarged Princess Mary of Cambridge. Cannes la Coquette I was sorry not to have time to go and see, having heard it highly spoken of by that fast-rising authority Mr. C. H. Hawtreys. With such a guide and in such a garden a more interesting Rose visit it were hard to pay.—A. C.

THE POTATO DISEASE.

THE Potato disease is to the fore again in the columns of the Journal, and well it may be seeing that it is so prevalent in fields and gardens. Like "A KITCHEN GARDENER" I am unable to accept the dictum of a correspondent on page 110, that "about one-half of the losses by the disease arises from the want of knowledge and apathy on the part of the growers." I have perhaps paid as much attention to the subject as the writer in question, and have made as many experiments in the selection of seed, manures, and mode of treatment as most people have, while I have certainly had more than "three-quarters of an acre" of land for experiment, or indeed three-quarters of a mile either. Our author thinks that with care in the raising of seedlings some may be produced absolutely disease-proof. Let us hope it may be so, but the prospect is not good. I can remember when the Fluke, Paterson's Victoria, Redskin Flourball, and some others were uninjured for a year or two. But what about them now? Then followed the Scotch Champion, Magnum Bonum, and Grampion; but I have seen all those varieties affected this year in a garden where the greatest possible care has been taken in their cultivation, and special means were adopted in selecting and preparing the seed. I am sorry to have to record this visitation, which was certainly not the result of "apathy" on the part of the grower, while his "knowledge," scientific and practical, of gardening in its widest scope is, perhaps, not exceeded by that of any reader of the Journal.

Ever since the terrible destruction of the crops in 1845 I have been "mixed up" with the malady, and this more than once to such an extent that, in common with others who have been employed "sorting" Potatoes for weeks together, the heaps often a mass of rotteness, our fingers have become diseased, and we have had to relinquish the work and enjoy a holiday with our hands in poultices. I have thus very intimately been "mixed up" with the disease, and from then to now have endeavoured to learn something about it practically, and to ascertain the conditions under which it spreads. Long experience has enabled me to distinguish the disease at a glance, and I am not mistaken when I state that it has attacked the varieties above named. And now, having submitted my credentials, I will refer further to this perplexing subject.

I do not attempt to enter on the philosophical part of the question and pretend to treat learnedly on spores, hyphæ, &c., or I might, as many have done before me, be floundered in a sea of scientific conjecture. Whether the roots decay by excessive rains and the plants become enfeebled and fall a prey to the apparently ubiquitous visitant, or whether the sap of the plants becomes impure by the foliage being overgorged and thus form a suitable nidus for the fungus, or whether the fungus is the original cause of the evil, matters not; the results are the same, and are governed by the same conditions—namely, a superfluity of moisture in the soil and air in combination with a high temperature.

It is well for men of science—and no one has a greater respect for those accomplished individuals than I have—to urge the importance of burning the haulm of the plants and destroying all diseased tubers instead of leaving them on the land; but I know from most carefully conducted experiments that our scientific friends have probably not tried, that if diseased haulm and tubers are dug into the ground, and diseased Potatoes are planted in that ground, that not a vestige of the murrain will follow if the season proves hot and dry, while during a wet, warm, and murky season the crops are liable to destruction in gardens where the above preventive measures have been rigidly carried out. That the burning of the haulm and diseased tubers is calculated to destroy a great number of diseased spores is certain; and if everybody—there is the point—would carefully carry out the practice indicated, much good would in all probability result; but for one or two individuals only in a parish to be thus diligent, the remainder being passive, will no more result in stamping, or rather starving, out the murrain than the persistent killing of flies by the same diligent few would end in the annihilation of those insects from the districts where they abound.

I will now record an instance bearing on the apathetic and ignorant part of the question. Last year a farmer planted several

acres of Potatoes on light sandy land. Had the summer been dry the produce would have been scabbed and worthless, but as it proved wet the crop proved valuable—realised in fact £30 per acre. If the seed had been carefully selected and special attention given to cultural details a good text would have been provided for a Potato-disease writer; but neither one nor the other was the case. The seed was just taken as it was, the small unsaleable tubers—the waste from a large store that many people would call "trash," yet a splendid disease-free crop was produced. Had the same sets been planted in rich wet ground the crop, like all others in such ground and district, would have been worthless. Seed from the above disease-free crop was again planted on poor sandy land this year, also on some heavier and better ground by the same owner, and in the former case the tubers are perfectly clean, in the latter they are seriously diseased. Much seed was sold of the celebrated crop referred to, and planted in many fields, plots, and gardens; but the disease is general in them all where the ground is low, wet, and at all rich. In such a case as this the selection theory breaks down utterly, and I have known it break down in a similar manner before. On the sandy soil referred to the rain passed through as if through a sieve, and that reason, and no other, was the cause of the clean healthy crop.

Soil so worked that the rain can pass through it freely, and much wider planting than usual, are the only modes that I find of avail in securing good and fairly sound crops of late Potatoes. Magnum Bonums and Champions are terrible soil-exhausters. Dwarf forms of those varieties with thick leathery foliage and woody-textured stems would be as welcome to Potato growers in this district where hundreds of acres are grown as would be a new planet to astronomers.

Hundreds of varieties of Potatoes have been raised during the past twenty years, but we have about as much disease as ever. Only the early varieties escape—those that are ready for digging before drenching rains combined with a high temperature call into action the fungus that devours the later crops.—A LINCOLNSHIRE POTATO GROWER.

FLORAL EXHIBITION AT THE ALEXANDRA PALACE.

ON Saturday last an Exhibition of bouquets and table decorations was held in the great hall of the above building. Very liberal prizes were offered in the several classes, which might have been expected to have induced a more vigorous competition than was actually the case. However, there were sufficient entries to occupy three long tables, and, the general arrangements being very satisfactory, the Exhibition fairly proved a success, a few groups of miscellaneous plants adding much to the effect.

Of the dinner table decorations there were several exhibitors who staged moderately tasteful examples of arrangement, but not marked by any especial merit. The prizetakers were Messrs. Dick Radclyffe and Co., Holborn; Mr. W. Soder, gardener to O. Hanbury, Esq., Holfield Grange, Essex; and Miss Annie Williams, Sutton House, Highgate, who obtained the awards in the order named. Bouquets were numerous in the three classes devoted to them, but comparatively little diversity was shown in the arrangements. The flowers employed in the brides' bouquets were chiefly *Stephanotis floribunda*, *Tabernaemontana coronaria* fl.-pl., *Eucharis grandiflora*, *Lapageria alba*, *Bouvardias*, *Gardenias*, *Pancratiums*, white *Pelargoniums* and *Spiræas*, with fronds of *Adiantums cuneatum* and *gracillimum*. Miss A. Williams; Mr. J. Prewett, Hammersmith; Mr. W. S. A. Saltmarsh, High Street, Chelmsford; Mr. J. F. Chater, Camberwell Road; and Miss E. Stuart, Seven Sisters Road, were the successful exhibitors of brides' bouquets. Of ball and bridal bouquets the best were from Miss A. Williams, Miss E. Stuart, and Mr. G. Phippen, Reading. Flower stands for a drawing-room table were fairly well shown by Messrs. Stuart and Prewett.

The principal feature of the display were the exhibits in the class for a vase of flowers not less than a yard in diameter. Prizes were offered in that class of the value of £5, £2, and £1, the result being that four competitors appeared. Messrs. Dick Radclyffe & Co. gained the chief prize with a large glass stand composed of a trumpet-shaped tube 4 to 5 feet high, at the base of which was a wide shallow basin. In the upper portion were flowers of *Lilium auratum*, bunches of Mountain Ash berries, with leaves of *Caladium* and Grasses. Around the stem were sprays of *Passiflora cærulea*, and at the base were *Liliums*, *Dahlias*, *Gladiolus*, *Delphiniums*, and small plants of *Ophiopogon Jaburan*—a bright and elegant arrangement. Miss Annie Williams was placed second with a large wicker stand containing a large number of flowers; *Gladiolus*, *Ixoras*, and *Bougainvilleas* being especially noteworthy. Mr. G. Phippen followed with an antique vase of flowers, *Clematises* being employed with excellent effect. Mrs. Sutton Abbott also obtained a third prize.

The general arrangements of the Exhibition were admirably carried out by Mr. J. Forsyth Johnson.

EFFECTS OF LAST WINTER.—Many of your correspondents have written from time to time on the effects of the severe frosts

Last winter on evergreens, Roses, &c., but I have not seen any remarks on the effects of the frost on what are always supposed to be hardy trees. In the county of Rutland and in the neighbouring county of Leicester many Apple trees have been killed, and I know of two or three old Walnut trees that have been very much damaged. Many Oak trees have not come into leaf at all, and are to all appearance dead, except that they are sending out small stunted shoots from the trunk. I should like to know whether this is the case elsewhere.—E. C., *Oakham*.

A DAY AT REIGATE.

As a Secretary of the National Rose Society I could not but regard with feelings of admiration the conspicuous place which Reigate has for years taken as a Rose-loving and Rose-exhibiting locality. The names of Messrs. Baker, Waterton, Heywood, Horne, Wollaston, Sargent, and Pawle are too conspicuous in our prize lists to leave any doubt as to the zeal and excellence with which Rose-growing is carried on there. A closer acquaintance, too, with the Roses of the neighbourhood gained at the local show, at which I have had the pleasure of assisting as judge for a couple of years, has only confirmed me in the conviction that it is amongst one of the most rosy localities with which I am acquainted. It was, then, with the anticipation of a pleasant and profitable day that I accepted the pressing invitation of my good friend Mr. Baker, one of the Vice-Presidents of our Society, to spend a day with him and to visit with him some of the gardens which had become famous as homes of the Rose. I was not disappointed. The day was perfection in point of weather—bright but not too warm; and the notes which I have taken of my day's visit may perhaps have some little interest for those who have heard of but have never seen the gardens which I visited.

HOLMFELS.

This is the residence of our worthy Vice-President Mr. Baker, and is situated just on the outskirts of the town nearly opposite The Priory, the residence of Lady H. Somerset. The garden is of considerable size and prettily surrounded with handsome trees, the bedding-out tastefully and carefully carried out; but the Roses are its glory. It is here that its owner delights to be employed, and where he has acquired such solid knowledge as to the capabilities and wants of the Rose. The soil of the garden is naturally light, and hence he has adopted as his stock (and in this he sees no reason for change) the Manetti, using the seedling Briar for Teas, but preferring above all to get the Roses on their own roots; and I must candidly acknowledge that I have nowhere seen more vigorous growth or more healthy-looking plants; indeed, I may go further and say that they are more vigorous than any I know. I have not visited the nurseries of Messrs. Cranston & Co., or the garden of Mr. Jowitt, from whence such marvellous blooms have come this year, but they must be vigorous indeed if they excel these. Mr. Baker's plan in making cuttings is to take them off about this time of the year, taking them with a heel, plunging them about 4 or 5 inches in the soil, if in a spent hotbed so much the better, and then in the spring potting them up; by this means good plants are very soon obtained. As Mr. Baker obtains the most highly recommended of the new Roses, English and foreign, he is able to pass a critical judgment upon them. Of the newer foreign Roses he speaks well of Léon Renault, bright cherry red, very sweet-scented; Louis Doré, brilliant red, which I have seen very good in many places; Paul Jamain, a fine Rose like Charles Lefebvre; Comtesse de Choiseuil, a good Rose, very much in the style of Marie Rady; Charles Baltet; Marie Verdier, a fine Rose of a novel shade of colour; Baron Taylor; Gaston Levêque, bright crimson red; Julius Finger, which Mr. Baker thinks a most excellent white Rose, improved on Capt. Christy; Madame Alphonse Lavallée, bright cherry red, good; Souvenir de Victor Verdier, very dark; William Koëlle, very like Alfred Colomb; and Innocent Pirola, a pure white in the style of Niphetos, but of better form, among Teas. Of the English-raised Roses he is greatly pleased with Harrison Weir, which is in truth a grand flower, and Duke of Teck, which is very brilliant, and Countess of Rosebery and Duchess of Bedford, both good Roses. Most of the more highly prized of the older Roses were here in grand condition, and showed how carefully their wants had been attended to.

WOODHATCH

Is the very beautiful residence of P. B. Heywood, Esq., whose excellent gardener, Mr. Ridout, is well known as a successful exhibitor. The Roses (for it is about them I must mainly speak) are grown partly in the kitchen garden ground, which is stiff, and partly near the house, where the soil is light. Mr. Ridout is an advocate for the Briar cutting as a stock in preference to either the Manetti or the seedling Briar. His contention is that the roots

of the seedling Dog Rose go down with a tap root, while those of the Briar cutting spread more along the surface, and he brought a rooted plant of it to illustrate his view. The roots were spread like a fan just under the surface, and his contention is that this being the case they are more likely to receive the benefit of any mulching or liquid manure that may be applied to them; and there is, I think, a good deal of reasonableness in the view thus taken. The growth that some of his plants had made was certainly very great. Such varieties, too, as do not always succeed well, Marie Baumann for instance, had shoots 5 and 6 feet long, and stout and vigorous. In the rosery near the house things were not looking quite so well: a great many of the standard Roses had been killed, and I believe they were all to be replaced with dwarfs, and standards done away with—a consummation which is to be devoutly wished for more widely still. The general condition of the dwarfs was excellent, but Mr. Ridout is no advocate for the Manetti. Amongst other things which I saw here was a collection of most wonderfully grown Chrysanthemums, the plants being well furnished to the very bottom.

GREAT DOODS,

The residence of A. J. Waterlow, Esq., whose able gardener, Mr. Brown, is well known as a most successful competitor at our metropolitan and provincial shows. The collection of Roses here is very large, and the plants are exceedingly well grown. Here there is a difference of opinion with regard to the stocks used, for although the soil is light Mr. Brown prefers the seedling Briar to the Manetti, and some of his plants grown on this stock were wonderfully fine. But a stock is here used which I have not seen anywhere else, the old Seven Sisters; it bears a considerable resemblance to the de la Grifferaie of the French, although the colour of the flowers shows them not to be identical. It is very vigorous and seems to suit this light soil admirably, the plants budded on it being very fine, and Mr. Brown says the wood works wonderfully well. The garden is especially strong in Tea Roses. Mr. Brown has generally taken the first prize for Teas, and a large number of this lovely tribe is grown in pots. Mr. Waterlow's garden is rich in many things, his houses being remarkably well filled with excellent plants well grown; but Roses were its chief attraction. Here, too, standards seem doomed, and after another season or two probably will disappear altogether. From thence we went to

STONEHOUSE,

The residence of S. Mordan, Esq. This is one of the most beautifully situated places in the neighbourhood. It stands on high ground, and a beautiful view is obtained over the Weald of Sussex, and its wonderful foliage. Great alterations have been made, and others are still in progress which will greatly enhance the beauty of the place. Here Roses are not a speciality, although I should not be surprised if they are taken up warmly. Zonal Pelargoniums are uncommonly well done, and a house full of the newest and best varieties was very gay. A Peach house, however, containing two trees on trellises was the most noticeable feature of the place. I have never seen a more remarkable case of good cultivation. One tree of Noblesse was over, but one of Princess of Wales was a perfect picture. There were at least twelve dozen fruits on it of nearly equal size. What these were may be gathered from the fact that last year there were 120 Peaches gathered from it averaging 10 ozs. each, the largest of them weighing 13 ozs. Begonias were bedded-out; but from what I have seen here as well as other places I do not think them very effective, nor are they likely to be much in favour for this purpose. Our last visit was to

WRAY PARK,

The residence of J. Simpson, Esq. A very beautiful place, where carpet bedding is carried out on a very large (to my mind much too large) scale. I should feel quite satisfied with that on the terrace, but when I saw and heard three or four men clipping away with shears, reminding one of the snick, snick, snick which one hears in a large hairdresser's shop, I could not but feel that it was labour thrown away which might have been much better employed. Mr. King, the gardener, is a very successful hybridiser of Begonias and Coleuses; and his house of Begonias, containing not only the very best varieties in commerce but his own seedlings, was a most attractive sight. I am no admirer of Coleuses, but one that he had which obtained a first-class certificate on Tuesday last (Pompador) was very effective. As Mr. King has all the best varieties I asked him to kindly furnish me with a list of what he considered the best Tuberous Begonias; this he has obligingly done, and I give it here as the opinion of a thoroughly well-informed and practical man:—*Singles*: Laurent Descours, Baronne Hruby, P. E. de Puydt, Leopold II., Massange de Louvrex, and Pearcei Vittelini, raised by Louis Van Houtte; Mrs. Howe (Laing);

Brilliant, I.e. Géant, Countess of Kingston, and Miss Briscoe, raised by Thibaut & Keteleer; Lelia (Fontaine), Rosea grandiflora (Lequin), Lady of the Lake (Rodger McClelland); Mentor, W. E. Gumbleton, and L'Abbe Froment, raised by Lemoine. *Doubles*: Comtesse Horace de Choiseuil, Lucie Lemoine, Gloire de Nancy, and W. E. Gumbleton, raised by Lemoine; Esther, raised by Bouchet.

This completed the tour of a tolerably busy day, one of the greatest treats of which was, however, the beautiful collection of paintings at Mr. Simpson's, comprising some fine specimens of the most celebrated modern painters, English and foreign, which Mr. Simpson possesses, and which I shall hope some day to have a more leisurely look over. There were other places—those of Mr. Wollaston, Mr. J. D. Pawle, and Mr. E. Pawle—which I hope also to see; but I have said enough to show, I think, that Reigate may well lay claim to taking a very foremost place in the records of horticulture.—D., *Dral*.

HINTS ON PROPAGATING.

A YEAR or so ago I told you of the difficulty I found in striking cuttings of a double Wallflower. Some time afterwards in the same year, border Picotee cuttings refused to root from a cause that appeared to throw light on the difficulty I had with the Wallflowers. The season was uncommonly wet, and the hand-glass over the Picotees having been taken off during rain, and replaced when it ceased, the soil appears to have become sour, and the majority of the cuttings failed to root. They were taken up and placed in a fresh compost, which was only kept moderately moist. In the following spring they began to grow, and ultimately made good plants. The Wallflower cuttings that had taken such an unaccountable time to root had been inserted in a shady situation under a bellglass kept closely covered in dry weather, and exposed during rain. Some that I inserted this spring in a sunny border and shaded with a piece of calico during bright sun have rooted satisfactorily.

I may mention in reference to this subject that a piece of *Euonymus*, having been thrown upon a weed heap in autumn, was covered there in a horizontal position. In March this was found to have callused, and it ultimately became a plant. Acting upon this hint, last autumn I made a mound in a north-west border, and stuck *Euonymus* and Wallflower cuttings in the sides of it horizontally. This mound was several times frozen through in the winter, yet by the middle of March most of the *Euonymus* and all the Wallflowers had callused, the latter indeed having produced roots. Both were then planted out and attended to for a while, and have become fine plants. It would be worth while to try cuttings of Hybrid Perpetual Roses in this way. The mound might be built up as the cuttings were placed in position.—A. BOYLE.

FLORAL DEFENCES.

(Continued from page 146.)

Glandular Hairs.—A very frequent mode of floral defence is constructed by the growth of hairs, each with a little glandular knob at the tip secreting a sticky fluid. These glandular hairs are so very common that they can hardly have escaped the notice of those field naturalists who care for flowers. Examples may be found in the Marsh Crepis, Alpine Circea, Mountain Barrenwort, Gooseberry, Linnaea, and many other flowers. But we must not infer that glandular hairs have no other value to the plant, or that they are always employed in keeping away disagreeable visitors. The Mountain St. John's wort is thickly beset with glandular hairs, though the plant secretes no honey, and therefore has none to guard. The sepals of some Poppies exhibit a forest of glandular hairs, but the sepals fall off when the flower opens.

Fig. 34.
Flowering
Gooseberry
(Kerner).

The sting of a Nettle is a tubular hair with a poison bag at its base; at the tip is a little knob, which breaks off on the slightest touch. The knob acts like a cork in keeping the poison from the air, and when it is broken off the pointed neck of the hair pierces the skin. When the leaf is crushed the tubular hair is compressed, and the poison-bag cannot discharge its irritating fluid.

Thorns, prickles, and sticky secretions are obviously more suited to be external defences, and we now come to the more delicate appliances for protection within the flower.

The common Foxglove has a floral defence which, though very simple, is effectual. The lower lobes of the bell on the inside are beset with stiff hairs, over which creeping insects and smaller honey-loving flies find it difficult to pass; but the humble-bee goes straight on, and even uses the hairs to push himself further in over the pearly surface which lines the bell. But why are the little bees excluded?

The four stamens and the pistil of the Foxglove are pressed closely against the inner surface of the bell, so closely that they are sometimes overlooked. A little bee that would not half fill the tube of the bell might pass under the anthers and get the honey without touching the pollen; but the humble-bee is so stout that it cannot help rubbing against the anthers and carrying off pollen. Now the Foxglove is one of those flowers in which the pollen is ripe before the pistil of the same flower is ready to receive it. This is one of Nature's contrivances to ensure cross-fertilisation; for if the pollen and the pistil were ripe at the same time, shut up as they are in the

Fig. 35.—*Cobaea scandens* (Kerner).

same tube, the pistil would be fertilised by the pollen from the same flower. So, as you may observe for yourselves, in the beautiful racemes of the Foxglove, the lower flowers come out first, and in some of them the anthers may already have ripened and withered when the pistil is ready for the pollen; whilst in the upper flowers the pollen is plentiful but the pistil scarcely to be seen at all, being not yet fully grown. Now the humble-bee begins with the lowest flower. He has come dusted with pollen from another Foxglove, and he finds the pistils of the lowest flowers ripe and ready to receive it. As he goes up from flower to flower he leaves pollen where it is

Fig. 36.—*Campanula barbata* (Kerner).

wanted till his coat is brushed fairly clean. When he reaches the higher flowers he finds no pistils, for they have not yet grown, but a profusion of pollen from the ripe anthers. Thus he gets his coat redusted with pollen and flies off to the lowest pistil-bearing flower of another like plant.

It is not difficult to see how the whole of this wondrous arrangement may rest upon the defensive efficiency of the little tuft of stiff hairs just within the bell of the Foxglove flower.

One of the most beautiful of our British wild flowers, the Buckbean or Bogbean, is protected in a similar way. The Yellow Iris or Water-flag has a similar defence.

Circlets of hair within the tube of the flower, and pointing inwards, are called by Dr. Kerner "weels," a name applied to wickerwork frames used for catching fish. Examples may be found in common

Speedwell and Red Valerian. It is almost impossible for small weak insects to pass the weels, but stronger insects have no difficulty in penetrating them; in fact, the weels may often serve as path-pointers to direct the proboscis of the welcome visitor to the spot where the drop of nectar lies concealed. Weels are to be found in many Gentians, Dead Nettle, Motherwort, Woundwort, Horehound, Verbena, Borage, many Lilies and Mallows, Cranberry, and very many other flowers common in fields and gardens.

We must not infer that the internal defences of flowers are always in the form of weels, otherwise we may be disappointed in looking for them where defences may be present under even more curious and interesting forms.

Sometimes the bases of the stamens are surrounded by tufts of hairs looking like little woolly muffs, as in *Cobæa scandens* represented in fig. 35.

In *Campanula barbata* the stamens are in the form of a figure of 5, the middle part being closely appressed round the pistil, and the bases of the filaments forming a receptacle for nectar, as shown in fig. 36.

In one or more species of *Pentstemon* four stamens are complete, whilst the fifth stamen is transformed into a kind of drop-bar completely excluding small insects from the nectar, which is, however, easily reached by the tongue of the bee. (See section of flower,

Fig. 37.—*Pentstemon* (Kerner).

fig. 37.) Older botanists have called this beautiful modification an aborted stamen. Such terms will have to be banished as utterly misleading.

(To be continued.)

CLAY CROSS HORTICULTURAL SOCIETY.

AUGUST 10TH.

THE twenty-third annual Exhibition of this Society was held on the above date. The weather was all that could be desired, and large numbers of people came to see what may be called the best Show in the county. The finances of the Society are in a prosperous condition, showing a surplus of £586, and if we may judge from the number of visitors who flocked to the Show the Society will add considerably to that balance. I will confine my remarks to the competition in the principal classes.

For a group of twenty plants, eight in bloom, six foliage plants and six Ferns, the prizes were as follows:—First prize £25, second £20, third £15, fourth £10, fifth £5. These liberal prizes brought out five competitors. The plants were arranged in the centre of a large circular tent 100 feet in diameter, each exhibitor having a section. They formed a very imposing group, the centre being filled with Palms and Tree Ferns on a raised platform, and the other plants sloped gradually to the margin. Messrs. E. Cole & Sons of Manchester were first, having *Erica Hartnellii*, *E. ampullacea vittata*, *E. Marnockiana*, very good; *E. Fairrieana*, *Allamanda nobilis*, *Dipladenia Brearleyana*, small but good; *Ixora coccinea*; *Bougainvillea glabra*, well bloomed; *Crotons Weismannii* and *Disraeli*, both well coloured; *Pritchardia pacifica*, *Latania borbonica*, *Kentia Fosteriana*, *Cycas revoluta*, *Gleichenia rupestris*, *G. Mendelli*, *G. flabellata*, *Cibotium regale*, and *Davallia Mooreana*. T. H. Oakes, Esq., Riddings House, Alfreton (Mr. Ward, gardener), was a very close second, the Judges being long in deciding on the merits of the two collections, Mr. Oakes' blooming plants being a long way ahead. They were *Erica Thomsonii*, *E. Aitoniana* and *E. Turnbullii*, very good; *Ixora Williamsii*, *Clerodendron Balfourianum*, *Statice profusa*, *Dipladenia amabilis*; a grand plant of *Kalosanthes coccinea* having upwards of four hundred trusses of bloom; *Croton Weismannii*; *C. angustifolius*, a large bush but deficient in colour; *Kentia Fosteriana*, *Latania borbonica*, *Cor-dyline indivisa*, *Dasylium glaucum*, *Dicksonia antarctica*, very good;

Adiantum farleyense, *Gleichenia rupestris glaucescens*, *G. dichotoma*, &c. Mr. Cypher of Cheltenham was a very good third, his best plants being *Erica Irbyana*, *E. venosa*, *Anthurium Schertzerianum*, *Gloriosa superba*, *Hæmanthus magnificus*, *Thrinax elegans*, *Crotons Weismannii*, *Disraeli*, and *majesticus*, all well coloured; *Gleichenia speluncæ*, *Davallia Mooreana*, *Adiantum trapeziforme*, &c. Mr. Dore of Clay Cross was fourth, and Mr. Haslam of Hardstaff was fifth with small plants compared with the preceding, but very good for amateurs.

In the class for six flowering plants Lady Ossington, Newark (Mr. Lyon, gardener), was first; and Mr. Reynolds, The Gardens, Ogston Hall, was first for three plants. For the corresponding class of foliage plants Mr. Lyon was again first for six, and Mr. Beard, nurseryman, Chesterfield, first for three. *Fuchsias*, *Pelargoniums*, *Begonias*, &c., were only fairly represented. There were about six lots of table plants staged, Mr. Ward being placed first with *Crotons Weismannii* and Lord Derby, *Dracæna marginata*, *Pandanus Veitchii*, *Cocos Weddelliana*, and *Aralia Veitchii gracillima*. Mr. Lyon was a good second, and Mr. Cypher third. Mr. Ward was also first for four Palms, Mr. Lyon second, and E. Cole & Sons third. In the group of plants arranged for effect Mr. Ward was first with a very bright lot composed of Palms, *Dracænas*, *Crotons*, Ferns, *Ixoras*, *Ericas*, &c. Mr. Webb, Kenham Hall, Newark, was second with very good plants, but arranged rather too thickly. Mr. Lyon third.

I must not omit to mention the group of plants sent from Chatsworth not for competition, which was very attractive and interesting, composed of *Peristeria elata*, *Disa grandiflora*, *Vanda tricolor insignis*, *Odontoglossum Alexandræ*, *Masdevallia Veitchii*, and other Orchids; *Ericas Fairrieana*, *Jacksonii*, *vestita*, *coccinea*, *Aitoniana*, *Turnbullii*, and *oblata*; *Amaryllis* in variety, Palms, *Crotons*, &c.

Cut Flowers.—There was not a very grand display in this class, Mr. Proctor taking first for eighteen and twelve Roses, Mr. Haslam for Dahlias, Mr. Ward for eighteen bunches of stove and greenhouse flowers. Bouquets were very good, Mr. Haslam being first, Mr. Dore second, and Mr. Cypher third. Mr. Cypher was first for wreath for ladies' head-dress.

Fruit was of good quality on the whole, Mr. Ward being first for a collection of eight dishes, Mr. Lyon second, and Mr. Webb third. Mr. Froggat, gardener, Wingeworth Hall, was first for black Grapes with small bunches of Gros Colman; Mr. Ward second with good coloured Hamburgs; and Mr. Lyon third. Mr. Ward and Mr. Froggat were equal first for white Grapes, the former with good Muscats, and the latter with very good examples of Buckland Sweetwater. Mr. Ward was first for Pines, Mr. Lyon second, both showing Queens. The other fruit classes were fairly represented, Messrs. Lyon, Webb, Ward, and Reynolds being the principal prizetakers.—G.

THE SHANKING OF GRAPES.

I NOTICED a short time since that you gave an opinion that shanking proceeded from improper root-action. This is also, I believe, the generally received opinion. From this I differ entirely. A Vine may be in first-rate condition, the roots, the wood, and foliage right, and yet the fruit will shank. Shanking proceeds from a fungus, which lights on the stem of the bunch. At first a tiny speck, it quickly grows, and when it surrounds the stem it cuts off all nutrition to the fruit below it, and it shrivels the stem and it dies. The upper part remains in full health and vigour, and the fruit grows and ripens as before. If it were from the roots being defective the whole bunch would go, which it does not. Stop mildew or fungus in your house, and there will be, I venture to say, no shanking. It is easy to verify what I advance by looking out sharply for the first appearance of the spot of fungus on the stem of the fruit bunch and watching its progress. When the shanking has taken place, cut off the bunch and magnify the part above the shanking. Now you will find the tissues are healthy and sound. If the damage came from the root this could not be the case, nor would the simple plan of cutting off the part that has shanked be of any avail, which it undoubtedly is. The best remedy for shanking in my opinion is sulphur on the pipes; but deal gently with it.—HARRISON WEIR, *Weirleigh*.

A PICTURESQUE GROTTO.—It may be interesting to those readers who take a lively interest in ferneries, to know that a fernery grotto of a very novel character has been completed at Park Royal near Bradford, the country residence of Henry Yendall, Esq. This curious but beautifully constructed Fern grotto is of a special character. The interior arrangements are indeed marvellous, and what with rugged rockwork, fairy fountain, rivulet, and cascade, together with the beautiful Ferns and Mosses, makes it a very pleasant retreat from the drawing-room and billiard room. The fernery grotto is erected on the north side of the mansion in a very shady aspect, and before entering you pass under several rustic archways leading from the drawing room, which also adds much to the beautifying of the outer grounds, and answers as a kind of surprise before approaching the grotto. In short the fernery has so many enrichments both

inside and outside that my humble powers cannot here describe or enumerate the various forms which have been so artistically worked out.—A NATURALIST.

AURICULAS FROM SEED.

I HAVE read with a good deal of interest Mr. Rudd's excellent article, on page 135, on raising Auriculas from seed. I have often raised Auriculas from seed before, though not exactly in the way described by Mr. Rudd. What I should like Mr. Rudd to inform me is, how to raise Auriculas from chaff or pounded husks. I wrote for and received a packet of the seed which Mr. Rudd advertised for sale as being from best named varieties grown by Mr. Thomas Woodhead, and bearing that gentleman's signature as a guarantee of good faith. On opening the packet I found, instead of a dozen or two good seeds of Auricula, a quantity of chaff or broken husks, and three shrivelled-looking bodies which may be anything. Will Mr. Rudd be so good as to inform me through your pages how I am to treat this chaff, and what I may reasonably expect as the result of sowing his packet of "seed?"—FLORIST.

[We have received letters from other correspondents complaining of the contents of the packets referred to, but the above will be sufficient for affording Mr. Rudd the opportunity of making such an explanation as he deems necessary.—EDS.]

THE POTATO CROP.

ON August 12th the lifting of the late sorts of Potatoes was finished, and the entire crop of early, intermediate, and late varieties is safe in the store sheds, a fine, sound, and abundant crop—so abundant that it has not only filled the ordinary shed to overflowing, but three other sheds besides. Thus has been brought to a satisfactory conclusion one of the most critical and important operations of the year, for "A KITCHEN GARDENER" is undoubtedly right in his opinion that "the weather alone rules the state of the Potato crop," and all our care in the selection of seed and in every point of culture proves vain in adverse weather. So clear was this made last year, that one wonders all doubts upon the subject were not washed away by the almost incessant rain that made 1879 so disastrous for the "noble tuber."

Although much finer than last year, the present summer has been a stormy one, with weather so unsettled and showery that it was only by taking advantage of the intervals of fine weather the crop has been saved. No regular hours are kept while the lifting is going on, for we then work from daylight till dark, knowing full well from dearly bought experience that the first rain after growth ceases in the tuber brings disease in its train. Repeatedly has this stern fact been explained in the pages of the Journal, and by no argument or fanciful theory can it be explained away or set aside. To grow Potatoes to perfection free from disease, we require a climate that affords fine weather to bring the soil into good order for the planting; warm genial showers for the promotion of strong unchecked growth, followed by hot dry weather to ripen the tubers. It is rare for our climate to answer to these conditions; it does so occasionally, and it is only by watchfulness and care that the crop can be saved from the ravages of disease in ordinary seasons. On the whole the present year may be regarded as generally favourable, affording fully the requisite conditions for planting and growth; and although the weather has continued unsettled, yet there has been enough intervals of fine weather to enable everybody in this district to save the crop. With few exceptions the haulm and foliage was fresh and green at the time of lifting, and so long and crowded, much of it being a yard high, that a couple of men had to go before the diggers to clear it away, making an immense heap of it off 2 acres of late Potatoes which will be turned to account for manure.

I planted a sack of Scotch Champion by way of trial, but shall discard it. It is of the White Rock type, yielding plenty of large, coarse-looking, hollow-eyed tubers, which when cut are decidedly yellow—a sure indication of inferior quality. It is unworthy of culture among high-class Potatoes, and is one more example of the fallacy of such popular terms as "blight-proof" and "blight-resisting." Both Carters' and Suttons' Magnum Bonum have yielded a heavy crop of magnificent tubers, handsome, smooth, and full-eyed. They appear to be identical in every respect, are very white when cut, inducing the hope that one may be able to report favourably of its quality this season. The Victorias and Regents are as usual excellent; I have upwards of thirty sacks of them for cooking for the winter and spring supply. Of the second early varieties Early Rose appears to me to deserve a higher place than has hitherto been given it. Badly cooked it is decidedly inferior, being close, heavy, and watery; but

steamed or cooked in water and well dried afterwards in the saucepan placed near the fire, it breaks and is as mealy as can be wished. Its heavy-cropping property is well known. In this neighbourhood, and I believe generally, it is in high favour among the cottagers, who say it always affords them a crop when other sorts fail. I planted six bushels of it in light soil this year, from which I have dug fifty-six bushels of large tubers for cooking, besides a fair proportion of smaller for seed.—EDWARD LUCKHURST.

AUTUMN MANAGEMENT OF GRAPES.

UNDER the above heading on page 118 "R. P. B." describes his very simple mode of Grape culture, the results being such that satisfy him. This means that the produce is excellent, for nothing short of that would satisfy so good a cultivator. Your correspondent also refers to some vineries that he visited last year in which fine Grapes were hanging, but the surfaces of the borders were "swamped" in the afternoon when the houses were closed, with the object of keeping down red spider. This plan of closing the houses with moisture "R. P. B." evidently disapproves, for he says if good Grapes continue to be grown there it will be in spite of the moisture. "A KITCHEN GARDENER" strongly endorses all our friend has said about never syringing nor damping vineries at any time, and thus the practice that is adopted by a majority of the best cultivators is powerfully assailed.

I am as adverse to pampering Vines as any gardener, and have had the good fortune to grow Grapes that have satisfied myself and a rather critical employer, the Vines at the least being forty years of age. I rarely syringed them, but found it absolutely necessary to employ atmospheric moisture against red spider by damping the floors occasionally, and especially when closing the house. For twenty years previous to my charge the Vines were syringed as well as the floors damped, and the said Vines are now as strong and fruitful as ever. Even if this is "in spite" of the treatment they have received, it is certain that treatment has not injured them.

My experience leads me to the conclusion that it is easy to lay down a rule founded on circumstances too local and circumscribed to render that rule a safe one for general application. When I see splendid Grapes grown under the damping system I hesitate to say that the system is unsound, and I have grave doubts if the dry system were substituted for it in the same houses that the Vines would be so clean and the crops so good.

I have grown Grapes in one of the wettest counties in England, and also in the driest. In the former case damping was not necessary, in fact the atmosphere was generally too damp; in the latter damping was essential, as the air was extremely dry. In the moist and dull district there was no red spider, in the bright and dry locality the pest abounded. "R. P. B." does not, I think, practise Grape-growing in a district noted for its arid atmosphere and brilliant sun, neither presumably does "A KITCHEN GARDENER;" they advocate, therefore, a system of management that is perfectly applicable to their circumstances.

But the first-named correspondent says the soil of his district is one where red spider "ought" to be at home. If he were growing Grapes on the limestone formation with an annual rainfall of 18 to 20 inches (I have known it only a fraction over 16 inches) he would have no doubt of its presence. He would, during a hot summer, see Vines in the open air devoured with it, and fruit and forest trees prematurely defoliated by its attacks; and I have a lurking idea that before he had grown Grapes in such a locality for three years he would be glad of a little water for cooling the air of the vineries, and I should not be much surprised if he occasionally indulged in the luxury of "damping down."

That Vines are often over-pampered, over-syringed, and under-ventilated I cordially agree, and "R. P. B." is doing good service by advocating a more simple and rational mode of culture; but if persons of less experience than himself apply his drying plan during a dry summer in an already much overdry district the Vines in the houses will, I fear, soon be in the same condition as those on walls in the open air—namely, covered with red spider.

If I were the manager of those Vines alluded to as bearing such fine Grapes I should continue the practice that answers so well. They are the best Grapes in that neighbourhood, and the houses are very light and lofty. The same plan in another district with lower or less light structures might not, and probably would not, answer half so well. "Three of us," writes "R. P. B.," on the page above quoted, "were inspecting the magnificent crops of Grapes" in question, and I think I was—ONE OF THE TRIO.

A HYBRID DOCK.—There is now flowering in the Botanic Garden, Manchester, a Dock of considerable interest. It is a cross

between *Rumex maritimus* and *R. sanguineus*, and possesses in a striking degree characters of both parents. The leaves are slightly broader than those of *R. maritimus*, but by no means approaching those of *R. sanguineus* in width, but the red veins are quite as prominent. The perianth segments are not fringed as in *R. maritimus*; the flowers are less in number to each whorl, but more than in *R. sanguineus* with the less leafy panicle of that species. *R. maritimus* is the seed parent. The plant has been raised here, and it now remains to be seen whether it may not, like *R. maritimus*, prove to be of only biennial duration.—T. ENTWISTLE.

THE LIMES, GREENFORD GREEN.

IN the course of an "outing" it is not unusual to meet with a place which, though comparatively unknown, is really both well arranged and well kept, reflecting great credit upon its owner and also the gardener in charge, and such is the case in this instance. The Limes is the residence of T. D. Perkins, Esq., and is situated near Harrow. It is built on a gentle declivity, of which the most has been made by the landscape gardener, the chief points being a very ornamental terrace wall with perhaps rather too many vases, a good expanse of turf about which are dotted a number of plain beds—these at the time of my visit being very effectively planted—belts of shrubberies, and large beds filled with a very great variety of choice Conifers, flowering, deciduous, and ever-green shrubs, a piece of ornamental water, Fern walks, and other arrangements. A well-built ornamental conservatory adjoins the residence, but unfortunately it is of necessity kept much too dry for the well-being of many plants suitable for the decoration of conservatories. The plants most freely employed are Zonal Pelargoniums and Coleuses, and of these there are many of the newest varieties, which with a few other plants maintain a very gay appearance at all times.

The plant and fruit houses are situated in the kitchen garden, and are very substantially built span-roof structures. They are kept in excellent order, the central walk forming a very agreeable promenade. One range consists of seven houses, the central and largest one being devoted to Grape-growing, one to Peaches, and the remainder to Melons, Cucumbers, Tomatoes, and plants. All kinds of fruit were carrying heavy crops—in fact, too heavy, the Peaches and Nectarines in particular. They were very healthy and were forced moderately. The best Peaches were the Royal George, Early Alfred, and Barrington, and the favourite Nectarine is the Elruge. In the earliest vinery the bunches of Black Hamburgh and Madresfield Court Grapes were of good size, the berries large and fairly well coloured. The Muscats in the later house look very promising. The borders are principally inside, and the soil used for both Peaches and Grapes consists mainly of strong turfy loam; and this, coupled with the fact of their receiving frequent liberal supplies of water and liquid manure, may ensure a better "finish" to the crop than would otherwise be the case in lighter soil. The Melons in various stages of growth were very promising; the varieties preferred are Suttons' Earl of Beaconsfield and Gemmett's Hybrid. Tomatoes are grown in pots, the best being Hathaway's Excelsior; Nisbet's Victoria has the appearance of being more ornamental than serviceable.

The roof of one plant house was covered with two plants of *Maréchal Niel* Rose, which Mr. Abbott, the able gardener in charge, succeeds in flowering splendidly every season. His practice, which is worthy of more general imitation, is simply to cut the growth hard back to near the main branches, thereby securing a number of long strong shoots, which are really requisite for a heavy supply of bloom of this very popular Rose. The collection of plants comprised many well-grown examples of choice kinds. *Allamanda Hendersonii*, *Clerodendron Balfourianum*, *Stephanotis floribunda*, and *Rhynchospermum jasminoides* were well flowered, and a plant of *Medinilla magnifica* was carrying fourteen fine racemes of bloom. *Croton undulatum* of good size was well coloured, and is an excellent variety. I also noticed good plants of *Davallia Mooreana*, *Lomaria gibba*, and *Areca Verschaffeltii*.

In another range of expensive but not particularly well arranged houses there were numerous well-grown tuberous-rooted Begonias, some of the best named varieties of which were *Rodwellii*, *Coultonii*, and *Vesuvius*. *Gloxinias* were well grown, and also the very useful *Torenia Fournieri*. A collection of Orchids is being formed, those in flower—some of which were of good size—were *Aërides odorata purpurea*, *Oncidium flexuosum*, *Dendrobium moschatum*, *Cypripediums*, and others. *Epacris* and *Ericas* were well grown, and the *Chrysanthemums* were remarkably vigorous. A few good exhibition varieties of bronze Zonal Pelargoniums grown there are *The Shah*, *W. E. Gumbleton*, *Mrs. Quilter*, *Prince Arthur*, *Black Douglas*, *Celebes*, and *The Czar*. There was also a good selection of stage Pelargoniums. The best of these were

Rob Roy, *Dr. Masters*, *Queen Victoria*, *Chameleon*, *Humphrey*, *Angelina*, *Prince Leopold*, and *Captain Raikes*. *Bridal Bouquet* is a very useful perpetual-flowering variety.

The kitchen garden was well stocked with all kinds of vegetables. The soil is a very stiff clayey loam, very difficult to manage. The fruit are very properly arranged in a quarter, and not distributed throughout the garden, as is too often the case, to the detriment of both the vegetable and fruit crops.—W. IGGULDEN.

MEALY BUG ON VINES.

IN hope that my experience may benefit those whose Vines are infested with mealy bug, I will state as briefly as possible how in my case I got rid of the pest. When I arrived here in May, 1878, I found one of three vineries pretty much infested—and as I fortunately had no previous experience of it on Vines, I was not a little annoyed at it. The fruits were ready to thin, and during the process I had full opportunity of seeing the extent of the pest. Every spare moment was devoted to the hunting all through the summer, but spare moments were not very plentiful that season, for reasons I need not mention; and by October I found them inside at least a dozen bunches, while they were more or less over the whole house of fourteen Vines. As the leaves turned yellow I took them carefully off by hand and burned them, pruning the Vines immediately after, and burned the prunings as well. Shortly after I had the Vines carefully scraped of all loose bark, and all round the spurs brushed with a narrow hard brush; I then with a strong pocket lens examined the rods carefully from end to end. With a paste made of clay and Gishurst compound every crevice was filled, and the whole coated over in the usual way with this same mixture, to which I added a good quantity of sulphur, and well mixed the whole with hot water. I then painted all the wood and wires of the house with two coats of strong white lead and turpentine, filling all the eyes of the wires and every other suspicious hole with the paint as we went on. I fully thought that they would be extinct after all this, but not so. Next spring at thinning time I found a few, and to my dismay every time I looked I found them more or less all through the summer. Still I saw that I was gaining ground, and I repeated the same process of stripping the leaves, and, if possible, was more stringent with the painting of the wood and wires, from which, I fancied, they must have come this spring when heat was applied. I resumed the watching, and have continued it up till to-day without seeing a trace of one. The fruit has been ripe some time, and is partly cut; and as a proof that no damage was done by stripping the leaves, the quality is better this year than I have seen it, while the remainder of last year's crop was sent to table on May 1st in good condition. I may add that I consider the strong point in the battle was removing the leaves before the insects retired to winter quarters. I examined the prunings as we gathered them in a sheet, and found hundreds on them which would otherwise have found shelter inside the house.—A. C.

[The above letter, written in reply to the one which appears on page 138 of our last issue, is extracted from *The Gardener* of the present month. The plan of removing the bug-infested leaves from the Vines, instead of permitting them to fall and the insects to remain in the house, is a most sensible one. We are able to confirm the observation of "A. C." that after the foliage turns yellow no injury whatever results to the Vines by its removal.—EDS.]

SUCCESSIONAL CROPS.

UNDER this heading, on page 132, "A KITCHEN GARDENER" remarks that it is now "too late to plant greens to come in well in either autumn or winter," and according to his ideas such crops only as Turnips and Spinach should be put in; whereas your Clonmel correspondent (page 134) finds that "no time is better than the present" for planting Broccolis. Probably both may be correct according to their respective climates, but the two experiences have the appearance of being rather contradictory. "A KITCHEN GARDENER" may be practising in a late and cold district, or, what is more likely, is satisfied with nothing less than heavy crops, and in either case he is then correct. In this southern district planting is still going on among the cottagers' allotment and home gardens especially, and I shall have plenty of applicants for my surplus plants of Broccolis, Kale, and Savoys for some days to come, according as they have the opportunity of lifting Potatoes and replanting. I do not advise them or anyone else to crop their ground with nothing but Turnips, or Turnips and Spinach as the case may be, but to sow a requisite quantity of each, and to fill the rest of the space with greens and Broccoli, taking care to

keep them watered during dry weather till established, and afterwards give an occasional soaking with liquid manure. The crop obtained may be comparatively light, but it may also be very acceptable. Such was the case here last season, and may be again, as I intend putting out a number of strong Broccoli plants on ground now occupied by the very latest Potatoes. The plants being rather tall will be laid in rather thickly, and I shall be deceived if we do not obtain a lengthened supply of useful heads. One of the best crops for planting at the present time is that of June or July-sown Cabbage or Coleworts, as, should they not heart well, they will be found useful as greens during midwinter, and the same remark applies to late-planted Savoy. —W. I.

At a meeting of the General Committee of the NATIONAL ROSE SOCIETY, held on the 10th inst. at the Horticultural Club, it was decided that the invitation of the Sheffield Botanical Society to hold the Provincial Exhibition in that town in 1881 should be accepted.

— THE PELARGONIUM SOCIETY has entered on its seventh year, and the new schedule now in the printers' hands will show that the managing body have abundant confidence, for the prize list is considerably augmented. At the annual meeting held a few days since some changes were made in the executive, certain of the more active officers being desirous of rest, while others filled with zeal for the Society's welfare were found willing to take their places. The following is a list of the officers as now arranged:—President, Mr. W. B. Kellock; Vice-President, Mr. Thomas Moore; Honorary Treasurer, Mr. H. Little; Honorary Secretary, Mr. Shirley Hibberd. To the Executive Committee were added Dr. Denny, Dr. Masters, and Messrs. King and Windsor. The schedule for 1881 will be precisely the same as that for 1880, save that, as remarked above, the prizes will in many instances be of greater value. The Exhibition of next year will be held in connection with the Conversazione of the Royal Horticultural Society on the 28th and 29th of June.

— A CORRESPONDENT writing from Penzance, Cornwall, informs us that VERONICA LINDLEYANA is now in full bloom, and is very handsome with its pure white flowers densely packed in racemes. It is an evergreen shrub, about 4 feet high, and succeeds well there out of doors, though usually confined to a greenhouse.

— In a small plant stove at Holme Lacey is a specimen of ALLAMANDA SCHOTTII that is bearing hundreds of fine blooms. It was planted last April in a compost of loam, charcoal, and half-inch bones, and the plant was allowed to ramble over the roof unchecked.

— SOME time ago we directed attention to the adaptability of MADAME PLANTIER ROSE for forcing, its profusion of white flowers being highly acceptable during April and early May. We have since had evidence of the great hardiness of this Rose. In a village in the north of England standard Roses are grown in many cottage gardens, the villagers having obtained Briars and budded them with the best varieties that were readily obtainable from the gardens of the squire and clergyman. Nearly all the plants were killed by the severity of last winter, but the variety that appears to have passed unscathed is Madame Plantier. It is now the solitary Rose in more than one garden, and the standards are covered with large clusters of pure white flowers. It is also one of the very few Roses that escaped the severity of the arctic winter of 1860–1861. Madame Plantier is not a show Rose, but is admirably adapted for garden decoration.

— As an instance of the effects of the winter on forest trees, we have recently observed that nearly all the LOMBARDY POPLAR TREES are dead or dying in a district embracing at least two counties in the north of England. Grand specimens 60 feet high that two years ago were in excellent health are now nearly leafless, and many actually dead. Younger trees have also suffered almost to the same extent, and even the young stock of this tree in some nurseries that we have seen are in a most unsatisfactory condition. The frost following the mild season of 1879 so suddenly and severely is the cause of the damage, and it has also greatly injured many Oaks and Larches, the tops of the trees being dead, similarly to those of Apple trees in many places in the south.

— FOR the fourth time in England the old French ceremony of CROWNING THE ROSIERE was witnessed at the Alexandra Palace on Saturday last by thousands of spectators. This old and pretty custom was first instituted more than thirteen centuries ago, and its representation on the occasion in question was admirably carried out. It was no mere burlesque or vain show, but the proceedings were conducted with an earnestness that impressed the visitors with a sense of unmistakeable reality. The procession of children with banners, the loud pealing of the organ, with the appropriate hymns sung by the choir, and the impassioned harangue of the officiating priest, rendered the ceremony highly imposing. The Rose Queen, a young girl of modest demeanour, was selected because of her excellent character and her devotion to her home and her care of an aged parent, and was crowned by the Rev. Father Nugee, of St. Austin's Mission, Walworth, after which presents were given to her and her attendants. So warmly was the representation received by the vast crowd, that there can be little doubt that the festival will become an annual one at the Palace, which the spirited lessee, Mr. Willing, and his excellent manager, Mr. Jones, are making so popular and successful.

— TRAINED to a wall in that portion of the Royal Botanic Gardens, Kew, devoted to herbaceous plants, is a specimen of the peculiar CLEMATIS DAVIDIANA, which is now flowering very freely. The leaves are trifoliate, each leaflet being roundish and very dark green. The flowers are borne in dense axillary clusters, and strangely resemble the single flowers of a Hyacinth. The sepals are light blue, the lower portion being erect, so that the calyx appears to be tubular; the upper portion is reflexed.

— THE fine old climbing plant ECCREMOCARPUS SCABER is too well known to need description, but rarely have we seen it to better advantage than we observed it in one of the college gardens at Oxford a week or two ago. A plant was trained to a wall with a southerly aspect, and in company with Cobæa scandens was growing most vigorously, the clusters of rich orange-coloured flowers being produced in profusion, and, intermingled as they were with the purple flowers of the Cobæa, formed a charming covering for the wall. The Cobæa had been placed out in the spring, the position being sheltered and warm.

— NEW offices, seed warehouse, and a manager's residence are, says *The Builder*, being erected by Messrs. WEBB & SONS at their extensive seed establishment near Stourbridge. The former comprise, on the ground floor, an entrance hall and staircase, with general waiting-room attached; a ledger-office, 60 feet by 24 feet, with manager's office at one end; fireproof-room, cloak-room, and lavatory, and a private staircase to the upper floor, on which are arranged a suite of offices for the Messrs. Webb and heads of the several departments, together with sample-room, cashier's office, and a spacious reading-room and library for the use of the employés, which is approached from the entrance-hall by a staircase of polished pitch-pine. The seed warehouse is in continuation of

the present buildings, and is five storeys high, each floor having an open space of 88 feet by 40 feet. Steam lifts and staircases are provided, together with offices for warehousemen, &c. The communications betwixt the new and present warehouses are to be closed by fireproof doors. Speaking-tubes are provided to all the offices, and the telephone is to connect them with the seed warehouses, which are on the opposite side of the courtyard. The buildings are being carried out by Mr. Lovatt from designs prepared by Mr. J. R. Veall, architect, Wolverhampton. The materials used are red pressed bricks, with Hollington stone dressings. The cost will be nearly £7000.

— ON the 10th inst. Mr. Alfred Sutton and Mr. M. J. Sutton, of the firm of MESSRS. SUTTON & SONS of Reading, accompanied their employes by special train to Portsmouth. As it is now a matter of difficulty on account of the size of the party (400) to find a suitable place for all to dine together, so in addition to the railway and boat tickets Messrs. Sutton gave to each man 5s. to provide himself with refreshments. Each married man had also a ticket given him for his wife. A number of the tourists passed over to the Isle of Wight, and all greatly enjoyed the day of change and wholesome recreation.

— MR. R. KIPPIST held the post of Librarian and not Secretary to the Linnæan Society, as was inadvertently stated last week on page 141 in a paragraph referring to his retirement.

— WE cite the following from "The Gardener," relative to the value of HALES' EARLY PEACH for forcing:—"The first week in June we received from Chatsworth a ripe fruit of this Peach, the forcing of which was commenced on the 28th of January. A sample of Elruge Nectarine, from a tree growing beside Hales' Early Peach, was just stoned, but not commenced to swell a second time. Royal George Peaches, started in the early part of November, were fourteen days behind Hales' Early, started 28th November. There are still earlier Peaches than Hales', but they are much less, and not so fine in other respects."

— THE same paper contains the following note on the DUKE OF BUCCLEUCH GRAPE—"Those who would like to see what can be done with this magnificent Grape should visit Tweed Vineyard and Drumlanrig, before the crops of it at these places have been encroached on with the knife. Mr. William Thomson informs us that the side of his corridor occupied by the Duke has the worst border of any in the Vineyard, and the treatment is nothing different from what he usually practises in the case of Black Hamburg. Here there is an even clean crop from top to bottom, on spurs and young wood alike. Mr. Thomson reckons his weight of it at half a ton; and he always gets a shilling or two more per pound for the Duke than for any other Grape he sends to Covent Garden at the same season. At Drumlanrig the whole of a sunken, semi-pit-like, span-roofed house, running east and west, is devoted to it. The effect of such enormous berries near the eyes is unique. There is scarcely a spotted berry in the house. Mr. D. Thomson says the border is very indifferent, having been made a month or two after he went to Drumlanrig, to produce a temporary crop of Grapes. Three years ago four grafts of the Duke were put in, and last year all others were cut away and the house filled from these grafts. The only difference Mr. Thomson makes in the treatment of the Duke is, that he gives a little more heat when it is in bloom, and, as a rule, all through gives more air. All who have seen these two crops of the Duke cannot but regret that so magnificent a Grape is so often met with in a bad state; and it is to be hoped that gradually it may take a more popular position in all Grape-growing establishments."

— A NEAT dwarf species of St. John's Wort is *HYPERICUM EMPETRIFOLIUM*, which rarely exceeds 9 inches or a foot in height.

The leaves are linear, about half an inch in length, and closely set on the stem. The flowers are small but very numerous, and of a bright yellow hue, each plant of moderate size forming a dense mass of colour that appears to excellent advantage among the numerous plants now flowering in a border of well-selected herbaceous plants. We recently saw a number of handsome little specimens in a suburban garden, where it is greatly prized.

— AN Ipswich correspondent writes us that the POTATO DISEASE is making serious havoc in that part of Suffolk. The progress of the disease was especially noticeable during the first week of August. Both early and late varieties are affected.

— A REMARKABLY distinct species of *Pentstemon* is now flowering at Kew—viz., *PENTSTEMON MURRAYANUM*, which rises to the height of nearly 7 feet, and bears in the axils of the glaucous stem-clasping or perfoliate leaves numerous tubular red or scarlet flowers. The peculiar form of the leaves, the bright colour of the flowers, and the extraordinary height of the stems render it very noticeable.

— IN the same garden *GUNNERA SCABRA* is now in most vigorous health, the leaves being of enormous size. The exceptionally fine clump at the upper end of the herbaceous grounds is now most conspicuous, and indicates the value of the plant for prominent positions in gardens.

— AN attractive plant is *NIGELLA HISPANICA*, and one of the best of its genus. The flowers are comparatively large, the sepals being roundish in form and of a dark purplish blue tint, which contrasts curiously with the reddish stamens and pistils. The petals, as in other *Nigellas*, are of peculiar form, but small and inconspicuous. The leaves and bracts are divided into numerous segments, but not so finely as in *Nigella damascena*, which is popularly known as Love-in-a-Mist or Love-in-a-Puzzle, both appellations referring to the involucre that is immediately below the flower. Another pretty species is *N. sativa* with very pale blue or white flowers, but it is inferior in decorative value to the two first named. They all flower abundantly during July and the present month.

— WASPS v. WALL FRUIT.—The advice in "Work for the Week," August 5th, 1880, for suspending bottles near the places the wasps frequent, leads me to mention the experience of two years, which was attended by great success. About a score bottles, half filled with a well-sweetened mixture of treacle and beer, were placed on a pyramid Pear tree in the middle of my large garden at a considerable distance from an orchard house and walls. Wasps and flies were attracted to the bottles, the contents of which were sought in preference to wall fruit.—J. J. T., *Herts.*

KALOSANTHES COCCINEA.

THIS old inhabitant of our greenhouses is not cultivated in such large numbers as it really deserves to be. When well grown it would be difficult to find a more lovely flowering plant than the old *Kalosanthus*. It is suitable for market purposes, for room decoration, as well as for the ornamentation of the conservatory, and lastly as an exhibition plant it is very effective. Its adaptability to bloom from June to the end of August, or later if retarded in its early stages, renders it more worthy of attention, especially when we consider *Pelargoniums* of the French and fancy type and *Calceolarias* are over, and *Heaths* are on the wane. At this time there is frequently a scarcity of flowering plants for the conservatory. In addition to the individual beauty of each truss it possesses a sweet fragrance.

Propagation is easily effected at any season of the year, either during the spring or at the present time; the latter in all probability is best as the plants go out of flower. Any shoots that have not produced a truss of bloom this year should be taken off and rooted, either singly in pots 3 inches in diameter or four or five in 5-inch pots, or more in larger sizes if required. Young shoots 4 inches long are preferable for cuttings, as they grow more freely

and make plants more quickly than the stems, although these will do providing a sufficient stock cannot be obtained otherwise. A small portion of sand should be placed at the base of each cutting; and if wanted to bloom next year the cuttings can be inserted in the pots they are intended to bloom in, while those for the following year's supply can be rooted in 3-inch pots, in which they will stand the winter and can in early spring be transferred into pots of a larger size. After the cuttings are inserted in pots they should be placed upon a shelf or in any position where they can be kept close for a short time.

The compost should consist of rich fibry loam, a seventh of manure, and plenty of coarse sand to keep the soil open. For all ordinary decorative purposes 4, 6, and 8-inch pots are large enough, but for specimens larger pots are required. The pots should be carefully drained. A layer of moss or a portion of the roughest of the compost should be placed over the drainage, and the soil should be pressed moderately firm. It is surprising what fine healthy plants can be produced in comparatively small pots. The roots should not be disturbed when potting.

Watering should be done carefully after the first potting, but when the roots have taken well to the new soil liberal applications can be given them, with occasional supplies of liquid manure and clear soot water. During the winter water must be judiciously applied, sufficient only being given to keep the plants from shrivelling, at the same time no attempt should be made to dry the plants until they lose their lower foliage, as is practised by some cultivators in order to induce them to flower. This severe drying is a great detriment to the plants both as regards appearance and the size of the flower truss.

The treatment during summer is simple when potting and watering are properly carried out. The plants will require a cool frame in the spring to protect them from frost and cold winds, ventilating freely on all favourable occasions. During June the plants can be placed outside in a sheltered position where winds will not injure them. To prevent the shoots being broken by the wind they may be secured to two or three stakes placed round the sides of the pots. By placing the plants outside the growth is rendered firm and short and becomes well ripened. They are sure to bloom well without being subject to the ordeal of drying during winter. As autumn approaches and there is fear of frost the plants must be placed in their winter quarters, where frost can be excluded, and the plants have a cool airy temperature and be placed close to the glass.

When exhibition plants are required it is necessary to take the points out of the young plants when rooted, or at the latest when 6 inches in length. It will be found that a young shoot will be produced from the base of nearly every leaf if strong cuttings are employed in the first place. These should again be stopped in spring, and so on through the summer, but not later than the early part of August. If rooted at once and kept in frames during summer, and stopping the shoots, dwarf plants about 1 foot high and the same distance through may be produced in twelve months having from thirty to forty shoots upon them. These are by no means in a condition capable of blooming the following year. Plants for exhibition purposes should be grown on from cuttings to the desired size before blooming them. Two sets of plants will be required to produce a supply of bloom each year unless small plants only are in request, which can be produced from the few shoots that fail to flower. The quantity of shoots that miss flowering will entirely depend upon the ripened condition of the plants and the time the shoots have had to develope. Few flowerless will be found from properly prepared plants.

Kalosanthes must have one clear season's growth, after which nearly every shoot will bloom. Plants that have bloomed should be cut back and kept close for a short time, so as to give them a chance of breaking again before winter.—WM. BARDNEY.

AUTUMN TREATMENT OF RASPBERRIES.

AMONGST small fruits none do better here than Raspberries. The soil and climate seem to suit them and they grow freely, but probably it is our mode of treating the canes that induces them to fruit so freely. I have just finished gathering the fruit. The old canes are bare, and the young canes form quite a hedge on each side of them. There are double the number of young canes that will be wanted or can be laid-in against the fence-like wires to which they are trained. To allow all to mature would be depriving the fruiting canes of much of their strength, and the mass the old and young canes make together would prevent many of them from ripening so well as they should. To secure this thoroughly, and allow the canes which will produce next year's crop to develope and ripen to the fullest extent, I have cut

away every old cane and all the small young canes which are not wanted for fruiting purposes, and the young fruiting canes are tied into their fruiting positions fully exposed to air and sun on all sides, and under this treatment I have no fear of their being killed by the next severe winter, or failing to produce a crop next season, however unfavourable the weather may be. Thoroughly ripened wood in all fruit-producing plants is always certain to reduce the influences of injurious weather to a minimum.—J. MUIR, Margam.

THE PHYLLOXERA.

THIS, the most terrible of all pests to which the Vine is subject, has not, fortunately, wrought anything like the destruction to Vines in this country that has been experienced in the vineyards of the Continent, where whole districts have been devastated by the scourge, and many industrious cultivators have been ruined. But that the Phylloxera does exist in England I have recently had undoubted proof, and the subject is adverted to now for the purpose of urging upon gardeners and others who are planting Vines the importance of rejecting those that show symptoms of being attacked by this most destructive insect, and to enable them to detect its presence on either roots or foliage.

The roots and foliage represented in the engravings (figs. 39 and 40) are truthful representations of the attacks of this dreaded insect in an English vineyard. As will be seen, the symptoms are so distinct from all other affections of the Vine that they cannot be mistaken, and all who have Vines that refuse to thrive and which have the

Fig. 38.—Phylloxera vastatrix.

Female specimens and their eggs. *a*, Antennae; *b*, horns or suckers; *c*, egg plainly visible in the body of the insect; *f*, winged form of the insect. All magnified.

foliage and roots similarly affected, may conclude that they are the victims of the greatest misfortune that can befall them as cultivators.

The Vines from which the specimens were taken are in charge of one of the ablest of British gardeners, whose name and habitation I am not at liberty to name at present, but I can give an assurance that so far as it is in the power of man to prevent it that the pest will not be permitted to spread, for the most thorough measures will be taken to utterly destroy it.

The Vines affected were planted three years ago in a very large house, and had the gardener been acquainted with the signs of the presence of the insects on the roots he would not now have to combat an attack so serious. He had seen engravings of the insects magnified (fig. 38), but had no idea of the appearance of the roots when attacked by them.

In one house the Vines were growing splendidly, in the other they made little or no progress. The borders in both structures were precisely the same, and the general treatment identical. The sickly Vines were, as the gardener said, "a puzzle," and he could "not make out what was amiss." Having travelled a little further than my friend and seen Phylloxera-affected Vines, my suspicions were aroused, and roots were sought for and found. The moment I saw them I was satisfied of their condition, and after holding a portion in the sun and under a lens for five minutes the heat made the insects uncomfortable, and at least a dozen of them on a portion of root only an inch in length began kicking and crawling, and the case was settled beyond dispute. The Vines were then searched for the leaf form of the insect, and dozens of leaves—the young lateral growths—were found affected precisely in the manner shown in the figure.

Much needless fear and anxiety have been experienced by many lest their Vines, which have not made satisfactory progress, were attacked by this destructive and, for a long time, hidden enemy, and it would not be difficult to point out instances where Vines have been destroyed on the assumption that they were Phylloxera-stricken when nothing of the kind was the case; but whenever the leaves are covered with galls in the manner indicated, and the extremities of the roots—the spongioles—assume a knotted form, or more properly become covered with nodosities, it may be at once admitted that the much-dreaded insect is present, and the work of

extermination cannot be commenced too promptly nor carried out too thoroughly.

In the instance under notice the Vines are fortunately in inside borders, and the attack also commenced in the centre of the house, the two end Vines not being nearly so much affected as the others. There is good hope, therefore, that the discovery was made just in time to prevent the Vines in half a dozen other large houses in the same garden being affected and speedily ruined.

The description and habits of the *Phylloxera vastatrix* by M. Planchon are as follows:—"Its best known form is that in which no trace of wings can be discovered. When the insect is about to lay its eggs (that is, in the adult female state), it forms a small ovoid mass, having its inferior surface flattened, its dorsal surface convex, being surrounded by a kind of fillet, which is very narrow when it touches the thoracic part of its body, which, formed by five rather indistinct rings, is hardly separated from its abdominal part of seven rings.

"Six rows of small blunt tubercles form a slight protuberance on the thoracic segments, and are found very faintly marked on the

abdominal segments. The head is always concealed by the anterior protuberance of the buckler; the antennæ are almost always inactive. The abdomen, often short and contracted, becomes elongated towards laying time, and there can be easily seen one, two, or sometimes three eggs, in a more or less mature state.

"The egg sometimes retains its yellow colour for one, two, or three days after it has been laid; more often, however, it changes to a dull grey hue. From five to eight days generally elapse before it is hatched. The duration of this period depends a good deal on the temperature. The quantity of eggs, and the rapidity with which they are produced, are probably determined by a variety of circumstances—the health of the insect, the quantity of nourishment it is able to obtain, the weather, and perhaps other causes. A female which had produced six eggs at 8 o'clock A.M. on the 20th of August had fifteen on the 21st at 4 P.M.—that is, she laid nine in thirty-two hours. Other females lay one, two, or three eggs in twenty-four hours. The maximum quantity is thirty in five days. The eggs are generally piled up near the mother without any apparent order, but she sometimes changes her position so as to

Fig. 39.—THE PHYLLOXERA ON VINE ROOTS.

Fig. 40.—THE PHYLLOXERA ON VINE LEAF.

scatter them all around her. They have a smooth surface, and adhere lightly to each other by means of a slimy matter which attaches to them.

"Hatching takes place through an irregular and often lateral rent in the egg, the empty and crumpled membrane being found among eggs in different stages of hatching."

The following interesting remarks on the genus *Phylloxera* by a skilled entomologist, "J. R. S. C.," have also been published in the Journal:—

"The genus *Phylloxera*, represented by such species as *P. coccinea*, *vastatrix*, and *quercus*, presents such strange anomalies that our entomological leaders are puzzled as to its place in this order. Like the scale insects, the females are oviparous, but the parents do not die off to furnish a protective coating for the young. In several instances broods in various stages of growth reside within galls formed on the roots or branches of the plants they attack, the *Phylloxera* resembling the aphides, in their succession of summer broods consisting only of females. Excellent, therefore, as are some of the remedies proposed, they have this awkward circumstance against them, that owing to the secluded habits of the majority of the *Phylloxera*, the killing agent cannot be placed near enough to them. As to their rapid multiplication, on the Oak leaves during July or August there may be observed, where the insects occur, a dozen or more of females upon a single leaf, each surrounded by her

batch of more than a hundred eggs, regularly arranged in circles. Some very startling statements have been published about these *Phylloxera* by the French naturalists, and not all of these have been verified as yet by sufficient observations. But it seems pretty well ascertained that the Vine-eaters, under certain conditions of their life, migrate to the Oak, and the reverse operation also occurs. Then the root-infesting *Phylloxera*, which are for many generations entirely subterranean in habit, are continued through a limited number of years by wingless females, until they die out, new colonies of the *Phylloxera* being propagated by the winged specimens bred from the leaves. And if we could credit M. Balbiani, that some females only deposit a single egg at the period when the winged development occurs (though another naturalist deems this a pupa), we should deem the *Phylloxera* pre-eminent amongst their brethren on account of their peculiarities."

If the species that attacks the Vine is proved as stated also to migrate to the Oak, the question, serious enough before, becomes more serious still, as the difficulty of stamping out the pest must be much greater than if its attacks were limited to the Vine.

After the pest has been extirpated from the vinery referred to the means that have been adopted will be published in the Journal, with some experiments with the insect that will prove interesting and possibly instructive. In the meantime all persons when planting Vines should closely examine the roots, especially the

extremities of the fibres, and if there is any suspicious swellings, any small tubercles on them, such Vines should be promptly destroyed.—J. WRIGHT.

NATIONAL CARNATION AND PICOTEE SOCIETY.

(NORTHERN SECTION).

THIS Society held their second Exhibition for this season on Saturday, the 14th inst., in the large Exhibition Building of the Botanical Gardens, Manchester, kindly lent by the Council. Although many of the exhibitors were considerably past their best, yet taken as a whole the Exhibition was very fine, whilst never at any former exhibition were so many good seedlings exhibited, the winning stands of Carnations in Class A containing a large proportion. Amongst the best of the seedlings was a scarlet hizarre of good quality, superb in colouring, exhibited by Mr. B. Simonite, and in our opinion either this or a beautiful flower of Admiral Curzon ought to have been awarded first honours. Mr. B. Simonite exhibited another fine s.b. Joseph Crossland, large, with a beautiful white, and strongly marked. In crimson bizzarres Master Fred was a splendid flower, large, with very bold markings, high in colour—a true crimson hizarre. The only fault we could find in the flower was the large or double guard petal, which must in all case detract somewhat from the beauty of a flower. It is, however, perfectly flat and free from the ridging which generally prevails in this kind of petal—in our opinion a very great fault. Other crimsones were Wm. Skirving, and two unnamed seedlings exhibited by Messrs. Gorton and Rudd. In pink and purples Mr. Gorton exhibited a splendid flower, whilst in purple flakes Mr. Rudd exhibited two, both good. In rose flakes fully a dozen new varieties were exhibited, all good; this class appears to contain a larger number of fine forms than any other, as many of them fully equal the present named sorts. One of the most noticeable was exhibited by Mr. Gorton, and which appears to be intermediate between a scarlet and rose flake, but which as it ages becomes a deep rose. Of older varieties Admiral Curzon and Rifleman were fine, whilst in purple flakes Dr. Foster was extra fine, large, and pure.

Picotees generally were not so fine as the Carnations; the reason is that those whose bloom was over had only soiled flowers, whilst being somewhat later (about a week) in blooming, those exhibitors whose situations were late were unable in many cases to exhibit in the stands to advantage; there was also an absence of good seedlings, which always make a stand look brighter. In reds the best were Lord Valentia, very neat and pure in colour; in lights Violet Douglas. Purples had Zerlina and Alliance, fine; in lights Minnie and Ann Lord were the best. Heavy roses had Lady Louisa and Miss Horner, fine; whilst in lights Miss Wood and Mrs. Allcroft were extra fine. The collections of single blooms were very large, and I do not recollect at any time for some years back seeing a larger number of single specimens, or a task that tested the capabilities of the Judges more. Mr. Dodwell was to the fore, and as usual did good service, and was sincerely congratulated by all on his improved health. The day was brilliant, and added greatly to the enjoyment of all concerned. The following is a list of the prizetakers and the principal varieties in each class:—

Class A, Twelve Carnations, open to all.—First, Mr. R. Gorton, Eccles, Manchester, with Wm. Skirving, fine petal, c.b.; James Cheetham, s.f.; Earl of Wilton, p.f.; Seedling, r.f.; Seedling, r.f.; Seedling, c.b.; Admiral Curzon, s.b.; Rifleman, c.b., extra fine; Seedling p. & p.b., a fine large flower; Seedling, r.f., very high in colour, intermediate between a rose and scarlet flake; Seedling, c.b., neat and good; Seedling, r.f. Second, Mr. George Rudd, Undercliffe, Bradford, Yorks, with Mars, s.b.; Seedling, r.f.; Seedling, p.f., very good; Seedling, r.f., fine in colour; Seedling, p.f., very pure in colour; Dan Godfrey, s.f.; Milton, c.b., extra good; Sir Charles Napier, s.b., extra large; Admiral Curzon, s.b., best flower in the stand; Seedling, c.b.; Seedling, r.f.; James Taylor, p. and p.b. Third, Mr. B. Simonite, Rough Bank, Sheffield, Mayor of Nottingham, p.f., extra large; Albion's Pride, c.b.; Sybil, r.f., large and good; Sportsman, s.f., fine; Seedling, r.f.; Seedling, s.b., large; James Douglas, p.f.; James Taylor, p. and p.b.; Joseph Crossland, s.b., extra fine; Mr. Battersby, s.f., extra large; Seedling, s.b., best. Fourth, Mr. J. Beswick, Middleton, Manchester. Fifth, Mr. E. Booth, Mobberly, Cheshire. Sixth, Mr. Jon. Booth, Failsworth, Manchester.

Class B, Twelve Picotees, dissimilar, open to all.—First, Mr. John Beswick, with *Miss Wood, medium rose; *Lord Valentia, h.r.; *Miss Horner, h. rose; Mary, l.p.; *Zerlina, h.p.; *Mrs. Allcroft, l. rose; *Ann Lord, l.p.; *Mrs. Lord, h. rose; *Minnie, l.p.; Edith D'Ombra, h. rose; *Violet Douglas, l.r.; Mrs. Harland, m.p. Those marked * were extra fine and large. Second, Mr. Jonathan Booth with Brunette, h.r.; Mary, l.p.; Miss Wood, m. rose; Zerlina, h.p.; Mrs. Summers, h.p.; Mrs. Allcroft, l. rose; John Smith, h.r.; Minnie, l.p.; Miss Horner, h. rose; William Summers, m.r.; Mrs. Lord, h. rose; Medina, h.p. Third, Mr. E. Booth, Mohherley, with J. B. Bryant, h.r.; Ethel, l. rose; Mrs. Bowers, l.r.; Brunette, h.r.; Zerlina, h.p.; Master Norman, h.r.; Mary, l.p.; Miss Lee, h. rose; Edith D'Ombra, h. rose; Minnie, l.p.; Mrs. Allcroft, l. rose; Medina, h.p. Fourth, Mr. J. Sharp, Perry Bar, Birmingham. Fifth, Mr. Geo. Rudd. Sixth, Mr. B. Simonite.

Class C, Twelve Carnations, nine dissimilar varieties, open to growers of four hundred pairs or less.—First, Mr. Thomas Mellor, Ashton-under-Lyne, with Sibyl, r.f.; James Douglas, p.f.; Crista-

galli, r.f.; J. Taylor, p. and p.b.; Sarah Payne, p. and p.b.; Admiral Curzon, s.b.; Dan Godfrey, s.f.; Sibyl, r.f.; Ivanhoe, s.f.; Juno, p.f.; Rifleman, c.b.; Lord Rancilffe, s.b. Second, Mr. Wm. Taylor, Middleton, Manchester, with Crista-galli, r.f.; William IV., s.f.; Jas. Taylor, p. and p.b.; Crista-galli, r.f.; Lovely Ann, r.f.; Lady Peel, p.f.; Admiral Curzon, s.b.; Lord Milton, c.b.; Admiral Curzon, s.b.; Clipper, s.f.; James Merryweather, r.f.; Annihilator, s.f. Third, Mr. John Fletcher, North Brierley, near Bradford, with Mars, s.b.; Seedling, r.f.; Mars, s.b.; Seedling, r.f.; Sibyl, r.f.; Sir C. Napier, s.b.; Seedling, r.f.; Sir C. Napier, s.b.; Seedling, c.b.; Juno, p.f.; Dan Godfrey, s.f.; Seedling, p.f. Fourth, Mr. Jas. Sharp. Fifth, Mr. Joseph Chadwick, Dukinfield, near Manchester. Sixth, Mr. Slack, Chesterfield.

Class D, Twelve Picotees, nine at least dissimilar, open to growers of four hundred pairs or less.—First, Mr. T. Mellor, Ashton-under-Lyne, with Ann Lord, l.p.; Norfolk Beauty, h.p.; Mary, l.p.; Mrs. Lord, h. rose; Miss Wood, l. rose; Violet Douglas, l.r.; Miss Horner, h. rose; Mr. Norman, h.p.; Rosy Queen, h. rose; J. B. Bryant, h.r.; Mary, l.p.; Bertha, l. rose. Second, Mr. R. Gorton, with J. B. Bryant, h.r.; Mary, l.p.; Mrs. Nichol, l. rose; Alliance, h.p.; Lady Louisa, h. rose; Mrs. Nichol, l. rose; Seedling 143, l.p.; Purity, h. rose; Zerlina, h.p.; Seedling 143, l.p.; Mary, l.p.; Mrs. Hannaford, l.p. Third, Mr. Wm. Taylor. Fourth, Mr. J. Chadwick. Fifth, Mr. John Fletcher.

Class E, Six Carnations, dissimilar, open to growers of 150 pairs or less.—First prize, Mr. S. Barlow, Stakehill House, Castleton, Manchester, with Sportsman, s.f.; Jas. Taylor, p. and p.b.; J. D. Hex-tall, c.b.; Jas. Merryweather, r.f.; Squire Meynell, p.f.; Admiral Curzon, s.f.

Class F, Six Picotees, dissimilar, open to growers of 150 pairs or less.—First, Mr. S. Barlow, Alice, m.p.; Fanny Helen, h. rose; Edith Dombra, h. rose; Ann Lord, l.p.; Mary, l.p.; John Smith, h.r. Second, Mr. Slack, with Mary, l.p.; Her Majesty, l.p.; Mrs. Auckland, h.p.; Mrs. Payne, h. rose; T. Williams, l.r., extra fine; J. B. Bryant, h.r. Third, Mr. James Sharp. Special prize for twelve selfs, yellows or other varieties.—Mr. R. Gorton first, and Mr. S. Barlow second.

Class G, Carnations, single blooms.—*Scarlet Bizarres*.—First and fourth, Mr. J. Beswick with Admiral Curzon; Mr. Miller third and Mr. William Taylor being sixth with the same variety; second, Mr. J. Fletcher with Mars; and Mr. B. Simonite fifth with a seedling. *Crimson Bizarres*.—Mr. Hewitt, Chesterfield, first, second, and third with Master Fred; Mr. J. Booth fourth with Lord Goderich; Mr. J. Chadwick fifth with Lord Milton; sixth, Mr. J. Fletcher with a seedling. *Pink and Purple Bizarres*.—Mr. J. Beswick first with Falconbridge; Mr. Hewitt second, fifth, and sixth with Sir G. Wolseley; and Mr. T. Mellor third and fourth with Falconbridge. *Scarlet Flakes*.—Mr. J. Booth first with Clipper; Mr. Taylor third with the same variety and sixth with William IV.; Mr. B. Simonite second with Sportsman; Mr. J. Sharp fourth with Lady Curzon; Mr. R. Lord, Todmorden, fifth with Annihilator. *Rose Flakes*.—Mr. J. Beswick with Jas. Merryweather; Mr. George Rudd second with a seedling; Mr. R. Lord third with Sibyl; Mr. Fletcher fifth with the same variety; Mr. R. Lord fourth with Mrs. Dodwell; Mr. R. Gorton sixth with Crista-galli. *Purple Flakes*.—Mr. R. Lord first, second, third, fourth, and sixth with Dr. Foster; Mr. J. Beswick fifth with Mayor of Nottingham. The premier Carnation was Master Fred, shown by Mr. Hewitt of Chesterfield.

PICOTEES.—*Heavy-edged Red*.—Mr. J. Booth first with J. B. Bryant; Mr. J. Beswick second, third, and fifth with Lord Valentia; Mr. G. Rudd fourth with Master Norman; Mr. E. Booth sixth with Brunette. *Light-edged Red*.—Mr. B. Simonite first with a seedling; Mr. R. Lord second and fifth with Clara; Mr. J. Beswick third with Violet Douglas; Mr. T. Mellor fourth with the same variety; Mr. T. Mellor sixth with Violet Douglas. *Heavy-edged Purple*.—Mr. E. Booth first with Zerlina; Mr. J. Chadwick second with Alliance; Mr. B. Simonite third with Zerlina and fourth with Mrs. Niven; Mr. Chadwick fifth and sixth with Miss Chadwick. *Light-edged Purple*.—Mr. T. Mellor first with Ann Lord; Mr. J. Beswick second and fifth with Minnie; Mr. R. Gorton third with the same variety; Mr. E. Booth fourth with the same variety; and Mr. B. Simonite sixth with Mary. *Heavy-edged Rose or Salmon*.—Mr. R. Lord first, second, third, fourth, and fifth with Miss Horner; Mr. Slack sixth with Mrs. Payne. *Light-edged Rose or Salmon*.—Mr. R. Lord first and second with Miss Wood; Mr. J. Beswick third and Mr. R. Lord fourth and fifth with the same variety; Mr. E. Booth sixth with Mrs. Allcroft. The premier Picotee was Miss Horner, shown by Mr. Robert Lord of Todmorden.

POTATOES IN WEST CORNWALL.—Early Potatoes have turned out a very fair crop this season and quite free from disease. The variety principally grown is Myatt's Ashleaf. Paterson's Victoria is also grown to some extent. The former is better suited to this locality than any other, it being a good early cropper, but if not taken up before the leaves turn brown is very liable to disease. Some were dug by the middle of May, and by the second week in June the greater portion was sent to the markets. They have, nearly without exception, been very scabby, much more so than they have been for many years. The leaves and stems of nearly all the late varieties are infested with the disease, and in several cases the tubers also. It is in the leaves and stems of Magnum

Bonum, but has not as yet touched the tubers. Speaking of *Magnum Bonums*, I know of a man who from 12 lbs. raised over 2 cwt. It is indeed an enormous cropper, and of excellent quality. —W. ROBERTS, *Penzance*.

M. CROUSSE'S NURSERY, NANCY, FRANCE.

I DARESAY many readers of this Journal are well acquainted with the name of M. Crousse, Nancy, and perhaps it might interest a few to peruse a short description of the establishment. The Tuberous Begonias are now in a highly attractive condition. Amongst them we notice the well-known single varieties, such as *Trocadero*, beautiful bright scarlet, flowers very large; *Graham Bell* and *Charles Baltet*, both beautiful deep crimson flowers, the colour of the latter is very intense; *Madame Valette*, *Madame Crousse*, and *President Hardy*, are showy varieties of deep carmine rose and rosy pink, and the habit is all that can be desired. *Oriflamme* is also worthy of notice, being of a bright crimson tinted with vermilion—the flowers are large and of great substance; *Pearcei* is well known and needs no comment; *Solfaterre*, having beautiful foliage and flowers of a bright yellow tinted orange, and many other good varieties. Amongst the newest single forms are *Albert Crousse*, light red, very free and splendid habit; *Madame Saladin*, white slightly tinted with cream; *Admiration*, rich scarlet, flowers very large and freely produced; *Exposition de Sceaux*, very large, of an amaranth colour—the large petals are extremely long, thus making it very distinct; *Countess of Kingston* is also very large and richly coloured; *Léon de Saint Jean*, extremely large foliage—the flowers are of a light scarlet, centre tinted orange, and for a mass of flowers one of the best; *Louis Puteaux* has also fine foliage and flowers of a deep crimson red, centre lighter, very free, and good habit. Amongst the doubles are *Comtesse Horace de Choiseuil*, light salmon rose, centre almost pure white, very free and fine; *Mons. Keteleer*, very full and double, beautiful flesh rose colour; *Edouard Morren*, bright crimson-scarlet, is also very large and double; *Gloire de Nancy*, rich vermilion, flowers large and freely produced, extra fine; *Clémence Delahaye*, deep satiny pink, centre white and yellow, flowers rather small but freely produced; *Madame Thibaut*, beautiful light sulphur very double and fine. But particular attention must be drawn to the double seedlings that were for the first time exhibited at the last meeting of the Horticultural Society of Nancy, and which for size of flowers and robust growth entirely supersede all others yet introduced. In one, of a salmon buff colour, the flowers are over $7\frac{1}{2}$ inches in diameter, and others of various shades of colour of reddish crimson, salmon, light buff, creamy pink, and reddish pink, are all large. The double white claims particular attention, being very double and large. All these, as well as many thousand seedlings, are planted in good deep rich soil shaded by trees and tiffany overhead; but it must here be stated that they have on an average from 10° to 14° of heat more than in England, consequently greatly aiding the full development of the extra large doubles.

The Zonal Pelargoniums are fine. Amongst the singles are *Madame Colson*, flowers very large, of a rich salmon, trusses large; also *Madame Chaté*, salmon tinted rose, flowers and trusses large; *Comtesse d'Olonnes*, deep pink; *Antoine Rosenkranzer*, trusses large, violet-amaranth; *Jean III.*, deep scarlet, superb; *Mrs. Moore* is a beautiful improvement in the oculated class. The doubles seem to do exceedingly well here. We see such as *Roi des Violettes*, very good; *E. About*, extra free and fine; *Emile de Girardin*, deep rose pink; *F. V. Raspail*, rich scarlet; *Gambetta*, flowers very large; *Madame Thibaut*, a very useful pink variety; *Mons. Gelein Lowagie*, lovely orange scarlet; *Madame Thiers*, a very fine double white; *Abel Carrière*, large trusses, salmon tinted rose, extra; *Paul Charbonier*, very large, double, orange scarlet; *M. Martha*, violet shaded amaranth; *Madame Léon Dalloy*, a peculiar shade of white tinted with lilac; *Comtesse H. de Choiseuil*, orange salmon, and for a mass of flowers equal to *Madame Thibaut*. We come next to the peltatum section of Pelargoniums. Single—*Flambeau*, large flowers, carmine rose, very bright; *Le Vésuve*, seedling from M. Dubus, flowers large, of a bright carmine red, colour distinct; *M. Dubus*, a splendid variety of a deep cerise carmine, extra fine. Double—*Gloire d'Orleans*, extremely free and double; *Madame Crousse*, a beautiful improvement in this class, flowers very large, of a beautiful soft fleshy rose, extra fine; *M. Dubus*, beautiful carmine rose; *Rosea plena fol. var.*, a distinct variety, beautiful rose tinted mauve; *Lucie Lemoine*, a useful variety; also *Sarah Bernhardt*, pure white, upper petals feathered maroon.

In the next house the ornamental foliage Begonias form a very interesting collection of the very best and newest sorts. The

following ten are the latest novelties raised at this nursery, all are good and distinct:—*Gaetan O'Gorman*, *Comtesse O'Gorman*, *Madame Champon*, *Murillo*, *Hermine*, *Distinction*, *Julie Sérot*, *Clémentine Gillot*, *Madame Henn Delasalle*, *Madame Edmond Deroux*, *Louise Chrétien*, exceedingly pretty; *Ondine*, *Madame Pigny*, *Monsieur Lefebvre*, *Titania*, *Madame Plassiard*, *Le Nubien*, and *Andalousie*. Coleuses are also very numerous, but many of the new ones so much resemble the older varieties that one often fails to see any improvement. Fuchsias are just commencing flowering, and consist of a fine batch of strong bushy plants. In the stove and temperate greenhouses we notice a good stock of such plants as Ferns, Anthuriums, Aralias, Bouvardias, Dracænas, Epiphyllums, Erythrinas, Stephanotis, and other handsome plants.

We now turn our attention to the plants outside, and the first collection that attracts our attention is the Rose, which is represented by a large number of good varieties. The collections of Chrysanthemums, Delphiniums, Pæonies, and Phloxes are very numerous; the batch of seedlings of the latter contains many fine varieties with large flowers and spikes. There is also a fine stock of bedding plants. These in the early part of the summer are very pretty and extremely free:—*Antennaria*, *Arabis*, *Aubrietia Hendersonii*, very useful when a mass of deep purple is required; *Polemonium cæruleum*, very pretty; *Sedums*, *Stellaria graminea aurea*, *Iresines*, and many other useful and ornamental plants for embellishing and making the parterres attractive. I greatly admired the healthy vigour of the plants and the cleanliness noticeable throughout the whole nursery.—AN OBSERVER.

A NEW GARDEN PUMP.

ARNOLD'S "Patent Simplex Garden Pump," represented on

Fig. 41.—Simplex Garden Pump.

fig. 41, appears to be a most valuable garden appliance. Having given it a fair trial we are able to say that it is one of the best water ejectors that has come under our notice, and will be useful in both gardens and forcing houses. It is very easy to work, maintains a continuous stream of water of considerable force, and cannot readily get out of order. It is so constructed that no indiarubber or other packing is needed; in fact, apart from the pipe by which the water is conveyed to the nozzle (and the wooden handle), there is nothing but metal employed in its manufacture. On the pump being placed in a pail or other vessel of water all that is necessary is to press down the piston, and the spring in the cylinder causes it to rise promptly for the next stroke, and whatever water is not forced through the nozzle passes down the interior of the cylinder, not a drop touching the operator. We shall be surprised if this most easily worked and efficient contrivance for washing wall trees, Roses, and plants generally, does not become a great favourite with amateurs.

It is a miniature garden engine of real utility, and possesses the elements of simplicity and durability in a very marked manner.

CUT FLOWER TRADE IN AMERICA.

THE cut flower trade for some years has been growing with wonderful rapidity, till now in New York city alone the business has reached several million dollars annually. Growers of cut flowers, realising that the day has gone by for the raising of general mixture, or "trash" as it is termed, now confine themselves principally to forcing two or three articles and growing them well. Thus we find on Union Hill, near Jersey City, one man who confines himself to growing Tea Roses, Jacqueminot Roses, and Violets; another to forcing Lily of the Valley, Hyacinths, and Lilies; while still another puts all his energies in the cheaper but just as important Carnation, Bouvardia, and Smilax.

Fashion wields her iron sceptre and dictates to her votaries the kinds and colours of flowers to be used, as she does in everything

else. Last winter she decreed yellow, and Niel Roses and Sun-flowers and yellow Pansies were in demand.

The forcing of Roses is perhaps the greatest branch of this great industry, and the quantity consumed is enormous. It is impossible to even estimate the quantity. It is known that in Philadelphia, at one of the Assembly balls, that not less than twenty thousand Tea Roses were used, beside Jacqueminot and other kinds. At one affair in New York over five thousand Tea Roses were recently used in the decorations. The five or six principal commission dealers in Boston, New York, and Philadelphia probably pass twelve or fifteen thousand Tea Roses through their hands daily. When it is considered that the Roses that these gentlemen sell are the surplus required it may give some faint idea of the quantity consumed in the three cities. It is asserted that one firm of growers in New York cleared over twelve thousand dollars in one season in Jacqueminot Roses alone.

Of course this is an exceptional case, and the growers sometimes lose heavily. For instance, one firm down east undertook to grow Maréchal on a grand scale, and the result was a break in the market, and a twenty-five dollar bud sold for three dollars a hundred, productive figure being about five dollars at that time.

In Carnation blooms the quantity consumed is still more enormous. One commission dealer last winter passed through his hands an average of fifty thousand a month between November and April, and then complained that he had not enough to supply the demand. He sold nearly thirty thousand to one firm in one month, and he was informed that that was two thousand a day less than his customer used, or ninety thousand that month consumed by one firm. There are probably from ten to thirty thousand Carnation blooms used in Philadelphia daily, and sometimes more.

A few years ago Lycopodium was used almost entirely for filling bouquets. Now it is almost altogether discarded, and Smilax has taken its place. So enormous is the consumption of this plant that there are growers of it entirely. One man in Philadelphia, who raises it in connection with one or two other flowers, has cut to date nearly ten thousand strings, and this is a mere drop in the bucket to the amount grown.

For the Grant procession in one of our western cities over five hundred strings were used to decorate the hose carriages of the fire department.

Lily of the Valley plays an important part in the trade, one gentleman in Newport having several houses of it, and is so skilful in blooming it that he is enabled to have it the whole twelve months of the year. One firm in Philadelphia also possess the secret. Of necessity the quantity consumed of this flower is much less than that of some of the other leading things. Still, thousands of dollars annually pass into the hands of the growers of this gem among flowers.

Of the cities in the Union, New York and Boston each consume the greatest amount, Philadelphia next, among the eastern cities, and Chicago and Cincinnati of the western ones. The two latter, and in fact most of the cities and towns north, south, and west of New York and Boston, draw their heaviest supplies from the two last-mentioned cities and from Philadelphia. The trade is still in its infancy, and before many years it is safe to say that the cut flower business will be one of the most important of the trades that supply the luxuries of life.—W. E. MEEHAN (in *American Gardener's Monthly*).

PORTRAITS OF NEW AND NOTABLE PLANTS.

BUCKLANDIA POPULNEA.—"One of the most beautiful evergreen trees of the forests of the Sikkim Himalaya, at elevations of 4000 to 6000 feet; also not unfrequent in the Khasia mountains, where, however, it does not attain the same stature; and of the mountains of Sumatra. From the elevations at which it grows in the Himalaya there is no prospect of *Bucklandia* being hardy in England, but as a greenhouse ornament no plant of the class can be more attractive. The trunk is cylindric and straight in well-grown trees, and, together with the oblong crown of evergreen foliage, attains 100 feet in height."—(*Bot. Mag.*, t. 6507.)

STENOMESON LUTEOVIRIDE.—"This is a new species from the high Andes of Ecuador, which flowered for the first time in the spring of 1879 with Messrs. E. G. Henderson & Son, of the Pine Apple Nurseries, Maida Vale. It is nearly allied to the well-known *Coburgia trichroma* of Herbert ("Bot. Mag.," tab. 3867), and quite similar to it in its cultural and climatic requirements."—(*Ibid.*, t. 6508.)

EPIMEDIUM PERRALDERIANUM.—"Is a native of the mountain woods of Babor, Foughell and Tababor in Eastern Khabylie, at elevations of 3000 to 5000 feet, whence it was introduced into cultivation by Dr. Cosson. The plants are perfectly hardy in Kew, and were presented by Dr. Reichenbach."—(*Ibid.*, t. 6509.)

CHIONOGRAPHIS JAPONICA.—"Though originally described by Thunberg nearly a century ago, this is a very rare and little known plant, of which we have seen no native specimens but those collected by Maximovicx in 1863, and one communicated by Captain Blomfield, R.N., in 1873. It is referred by Mr. Baker in his valuable paper on the aberrant tribes of Liliaceæ to the group *Heloniæ*, and its immediate affinity is with the Eastern N. American genera *Helonias* and *Chamælorium*. It is the only species of the genus. This very singular plant was raised from seed sent by Mr. Maries to Messrs. Veitch, with whom it flowered in April of the present year."—(*Ibid.*, t. 6510.)

AGAVE HORRIDA.—"This is one of the best known of the smaller Agaves, with a distinct continuous horny border to the leaf. It was introduced from Mexico by Verschaffelt in 1862, and is now to be found in all the more complete collections, but usually under the name either of *Regeliana* or *Desmetiana*, both of which rightfully belong to species of another section."—(*Ibid.*, t. 6511.)

KITCHEN GARDEN.

THE fine weather that has prevailed for several days has proved of great value for the eradication of weeds, and those have acted wisely who have plied the hoe freely. The watering of certain crops must be attended to, for it must be remembered that in consequence of a prolonged term of dull moist weather the roots of many plants are near the surface, and the crops are not in a good condition for withstanding drought. Celery, Strawberries, and recently planted crops of all kinds must be watered copiously if the dry weather continues. Look out for the second hatch of the Celery fly; a pair of sharp eyes and nimble fingers exercised for a few hours daily, finding and pinching sharply the small blisters immediately they are perceptible, will prove of great benefit to a valuable crop. Slugs are attacking the beds of young Cabbages. Frequent dustings of freshly slaked lime are highly useful provided the work is done at the right time. One dusting at ten o'clock at night when the slugs are feeding will be more effectual than ten dustings by daylight when they have retired to their haunts. There is more labour wasted by attempting to kill slugs by daylight than by almost any gardening operation. Ten minutes' work after dark will save hundreds of young Cabbage plants.

HARDY FRUIT GARDEN.

Fruit trees of all kinds are making much wood, due in a measure to the scantiness of the crop, the moist condition of the atmosphere, and the rains of June and July. All the shoots not required for extension should be cut back to within three or four leaves of their base, except shoots of Apple and Pear trees, that in some instances only grow a few inches and have the points terminated by a plump bud, which is invariably a fruit bud, and from which is produced the finest fruit. Similar remarks apply to Plums, also Cherries, especially Morello. Shoots 3 or 4 inches in length should not be shortened, as that would cause fresh growth to start from the base instead of inducing the formation of spurs. The leading shoots may be stopped at from 9 to 12 inches of growth, extension being desired as in young trees; but full-sized trees should have the extremities cut back similar to the side shoots. Any gross shoots likely to interfere with the symmetry of the specimen, or impoverish the weaker parts, should be removed. Wall trees should be examined frequently, tying or nailing-in extensions, and cutting back or removing breastwood, so as to admit all the air and light possible to the spurs and next year's bearing wood. Lay-in the wood of Peaches and Neectarines rather thinly, stopping any laterals on the strong shoots at the first joint, and cut-back any that are very vigorous. The Raspberry season being nearly over the old bearing wood should at once be cut out, and the young canes thinned to four or six of the strongest and best placed, which should be secured to the trellis if there be one, or left loose if they are afterwards to be secured to stakes, though in exposed situations it may be advisable to secure them loosely at once.

Wasps are so troublesome that to protect fruit from their ravages only netting that will effectually exclude them should be employed; and as autumn fruit is so scarce generally, no time must be lost in netting bushes of Red Warrington and other late varieties of Gooseberries, also Red and White Currants and Morello Cherries. If these are against walls with a north aspect they will keep in good condition longer than those in the open. Gather Apples as soon as they are fairly ripe, as most early Apples deteriorate in quality by being allowed to remain long on the trees. The crop of this useful fruit is very light, hence the necessity of greater care. Similar remarks apply to early Pears as to early Apples. Ground intended to be planted with Strawberries should be prepared and planted with as little delay as possible. Rich and deep ground and an open situation should be selected, the soil being deeply trenched and heavily manured, as the plants endure drought better than those in shallow soil. Plants established in 3-inch pots are the most suitable, placing them out in rows 30 to 36 inches asunder, and half those distances apart in the rows for the first year, every other plant being removed when the crop is gathered.

FRUIT HOUSES.

Figs.—The second crop of Figs being gathered attention must be directed to the maturation of the growths; and if former instructions have been followed in thinning and regulating the shoots and spurs little remains to be done beyond careful ventilating and watering. Water will only be required to prevent the borders becoming dry, the syringe being employed to keep down insects. A free circulation of warm dry air should be maintained until the foliage indicates signs of ripening. Where, however, the wood is crowded by all means thin it at once. Trees that produced a crop in June will now be ripening off another crop, and may be assisted by liberal supplies of water or liquid manure. Trees in pots never grow so strongly as those planted out, and this tends to the more certain maturity of their wood, hence they may be removed to the open air after the crop is gathered. Trees planted out should not have the sashes removed, but the house must be freely ventilated, as from the more vigorous growth of such trees they will need more time to ripen the foliage.

Melons.—The weather for the past few days has been all that the grower can desire, good fruit consequently being very plentiful. Before the fruits are very ripe they should be cut with a good portion of stem, and placed in a dry cool place so as to prolong the season of supply. Fire heat may safely be dispensed with during a continuance of such weather, closing the house early and maintaining a moist atmosphere to all plants other than those setting or ripening fruit. Under ordinary circumstances the houses, pits, and frames may be closed and the plants syringed at 3 P.M., but span-roofed houses should not be closed for half an hour later. For healthy and robust plants shading may almost be dispensed with, and less atmospheric moisture will be now required, especially by plants in frames. If the last batch of plants are weakly afford liquid manure about twice a week, but do not apply it very freely until the fruits are set, after which earth-up the roots with good lumpy compost. The last batch of plants in pits and frames will be setting the fruit, and must have a dry atmosphere with a little ventilation at night stopping each lateral one joint beyond the fruit. Continue to support fruits that are becoming heavy by means of tables placed beneath the trellis, and those in frames should be kept from the soil by slates, and when ripening may be elevated on small pots.

Cucumbers.—The general treatment for these continues the same. Plenty of atmospheric moisture, liberal feeding at the roots, free stopping and training the young growth, and thinning out the old being the chief points. Encourage the plants for autumn fruiting to make a strong growth, adding a little fresh soil as the roots penetrate through, abundance of surface roots being a true indication that the plants are doing well, maintaining a firm condition of the bed so as to induce short-jointed wood. A little fire heat should be employed on cold nights to prevent the temperature falling below 65°. Take advantage of every opportunity to collect and prepare soil for the winter plants, clearing the house of exhausted plants, remedying any defect in the heating apparatus, thoroughly cleansing the interior and exterior of the house.

ORCHARD HOUSE.

Apricot trees grown in pots in this structure will generally by this time have ripened their fruit, and as soon as this is all gathered the trees may with advantage be placed outside in a warm situation fully exposed to the sun, the pots being plunged in ashes. The trees should be well syringed every evening, and must be duly supplied with water at the roots. Peaches and Nectarines now becoming ripe must never be allowed to drop from the trees, even into a net. An examination of the trees should be made daily, removing the ripe fruit carefully with the hand, and as soon as the fruit is gathered syringing must be resorted to, to cleanse the foliage of insects. Where Pear trees are grown in pots some of them may be placed out of doors, as this will be likely to improve the quality of the fruit, while some may be near a north wall with a view to retarding the ripening process, thereby prolonging the season of particular varieties. It is not advisable to place Plum trees outdoors unless it is desired to retard the season of ripening. Figs will be ripening their fruit, and must be kept dry overhead and drier at the roots than during the swelling of the crop. Where Royal Muscadine, Black Hamburgh, or other early Grapes are trained over the pathway the fruit will be ripening, and will remain in condition for some time providing the fruit be kept dry. All fruit trees, whether in pots or planted out, should be kept somewhat drier at the roots as their fruit approaches ripeness. Ventilate freely at night as well as by day unless the weather be very cold and wet, or during the prevalence of high winds. Birds and insects must be excluded by hexagon netting.

FLOWER GARDEN.

Flower beds and borders will now be in their full beauty; every effort should be made to keep them in as good condition as possible. It will be necessary to examine the plants frequently, removing any dead or decayed leaves and flowers, trimming, regulating, or pegging the growth of such plants as Verbenas, Petunias, &c. All seed pods should be removed immediately they are formed. Any beds showing signs of exhaustion should have liquid manure liberally; but in the case of Pelargoniums, except such as are grown for their foliage, water should be sparingly given, or it will have a tendency to provoke growth at the expense of flowers. Any defects in the present season arrangements should be noted for avoidance another season, and any alterations intended should be decided on, so that an increased or diminished quantity of particular varieties may be provided for carrying out the proposed alteration. Insert the necessary stocks of cuttings of Pelargoniums so as to have them thoroughly established before winter. Herbaceous Phloxes are very fine this year, they should now be increased by cuttings inserted under handlights. It is hardly possible to have too many Clove Carnations, Pinks, &c., in gardens. Cuttings now inserted on a north border under handlights will root slowly but surely if kept close and moist until growth commences. Push forward the propagation of Daisies, Primroses, Polyanthuses, Forget-me-nots, Gentians, &c. Roses promise to be abundant and fine this autumn, but mildew is prevalent; prompt measures should be taken to arrest its progress, dusting the trees whilst damp with flour of sulphur. Should dry weather prevail liberal supplies of liquid manure will greatly assist a free growth. Climbing Roses, as Maréchal Niel, Climbing Devonensis, Gloire de Dijon, and similar varieties should have all the old wood that has borne flowers cut out, and the young shoots of medium size laid in not too thickly for next season's flowering.

PLANT HOUSES.

Orchids.—The East Indian house must be kept moderately close, and a growing atmosphere maintained; but if the weather be dull the moisture must be reduced, and recourse had to fire heat to maintain a temperature of 65° at night and 75° by day, the house being syringed and blocks damped at about three o'clock, the shading being withdrawn as soon as all fear of the sun scorching the foliage is past. Aërides, Phalænopses, Saccolabiums, and Vandas should receive every encouragement, and care must be taken to avoid giving a check, or it will result in stunted irregular growth. Be careful with Phalænopsis, as if the sphagnum becomes soddened the leaves will soon be diseased. Dispense with shade on the Cattleya house altogether, as light is of the greatest importance for the ripening of the pseudo-bulbs;

indeed Barkerias, Cattleyas, Dendrobiums, Epidendrums, Lælias, Oneidiums, &c., unless thoroughly ripened will produce weak and deformed flowers, followed by a weak after-growth. *Calanthe Masuca* and *C. veratrifolia* may now be repotted. If the soil is soddened carefully shake it out, washing the roots in tepid water, repotting in equal parts turfy loam and peat, adding a little decayed manure and some pieces of charcoal about the size of nuts, all well mixed together, affording about 2 inches depth of drainage, and keeping the plants about an inch below the top of the pot. *Calanthes vestita*, Veitchi, and Warneri, also *Limatodes rosea*, should have a maximum of light, heat, moisture, and air, watering with weak liquid manure, which will assist the growth of the pseudo-bulbs.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, King's Road, Chelsea.—*Illustrated Catalogue of Hyacinths and Bulbs, and List of Strawberries.*

Benjamin S. Williams, Upper Holloway, London, N.—*Catalogue of Bulbs, Fruit Trees, New Plants, and Roses.*

Newport Pottery Company, Monmouthshire.—*Illustrated Catalogue of Garden Pottery.*

Thomas S. Ware, Hale Farm Nurseries.—*Catalogues of Bulbs and Hardy Plants.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Bulbs.*

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (*D. L. G.*).—The "Orchid Growers' Manual," published by Mr. B. S. Williams, Victoria and Paradise Nurseries, Holloway, London, will probably answer your requirements. Its price is 5s., post free 5s. 5d. The term "zonal" has reference to the coloured zone in the foliage of Pelargoniums.

Love in a Mist (*Powis Square*).—Several species of *Nigella* are now flowering in the Royal Gardens, Kew, and other places.

Crested Moss Rose (*J. R. & Sons*).—The buds you have sent are of the above attractive variety, which we have grown for more than thirty years. It is often found in old gardens and some nurseries, and is worthy of more general cultivation. It succeeds well worked on the Briar stock.

Cuttings of Tea Roses (*J. B.*).—The writer to which you refer does not grow Roses or Rose cuttings for sale, indeed the Roses about which he writes are not his but his employer's. We can only suggest that you purchase a few plants from a nurseryman, and you will then be able to carry out your project.

Strawberries in Light Soil (*Idem*).—If the soil is made firm before planting and it is mulched with manure, and the surface further thickly covered with straw or other littery material as soon as the plants commence flowering, to keep the ground cool and moist, we think you may succeed in your object. The best varieties for your purpose are *Vicomtesse Hericart de Thury* and *President*.

Black Hamburgh Grapes (*S. T. N.*).—The Grapes sent, so far from being "perfect," are very faulty indeed. They are of good size, but destitute of colour, texture, and flavour. The Vines are either overcropped or require more support than they have received, and we also suspect they also require more ventilation.

Violas (*G. G. K.*).—The varieties do not succeed equally well in all soils and situations, and there are none that can be depended on for producing "a continuous spring, summer, and autumn display in a hot dry soil" in the south of England during an ordinary hot summer. Try the following:—*Yellows*: *Sovereign*, *Dickson's Golden Gem*, and *Chieftain*. *Blue or Purple*: *Blue Bell*, *The Tory*, and *Royal Visit*. *White*: *Pearl*, *Purity*, and *Nonpareil*.

Rose Annuals (*Canadian Inquirer*).—The "Rosarians' Year Book," edited by the Rev. H. H. D'Ombraim, Honorary Secretary of the National Rose Society, is published annually, price 1s. Messrs. Benrose & Sons, 10, Paternoster Buildings, London, are the publishers. The "Rose Annual," which contains excellent coloured plates of new Roses, can be had from the author, Mr. William Paul, Waltham Cross, Herts, price 5s.

American Blight (*Inquirer*).—Your trees are much infested with this insect. Syringe them with a very strong solution of soft soap, 6 ozs. of soap being dissolved in a gallon of water, to which may be added half an ounce of paraffin. A solution of nicotine soap of the same strength will also destroy the pest. In the winter scrub the trees with brine, applying also paraffin with a brush to those parts where the insects most abound, but not dressing the smooth bark of the trees with the oil, or it may seriously injure the trees.

Gladioluses Dying (*J. R. W.*).—They are, we fear, attacked by the disease that is often so destructive to these flowers. We know of no remedy, and we can only suggest that you procure healthy corms from a fresh source, and keep them separate from your own stock, and also plant them in a fresh place. The disease appears more pronounced in rich highly manured soil than in ground well worked and sweetened, but only moderately fertile in character.

Vine not Thriving (*R. P. O.*).—You erred by dishudding in the manner you describe, but that is not sufficient to account for the blistered and warted condition of the foliage. There are no insects on the leaves, but the sap vessels are ruptured, and in this state the Vine cannot grow. We are, without sufficient data to guide us, quite unable to account for its present unsatisfactory state, and we think you will lose time by attempting to restore it. We should dig it up and plant another Vine. A healthy young Vine planted carefully at once would make good growth the present season.

Trees for Orchard House (*W. B. W.*).—Peaches and Nectarines potted as maidens commence bearing the second year when well managed, and improve yearly with judicious treatment. The leading fruit nurserymen specially prepare trees for growing in pots, and you had much better purchase such trees than attempt growing your own. Healthy young trees may be removed from the garden into the orchard house, and if the transplanting is carefully done early in the autumn just as the foliage commences changing, a moderate crop may be taken the following year, but everything depends on the condition of the trees and the treatment to which they are subjected. Notes on the management of orchard houses are given from time to time in our "Work for the Week" columns.

Cropping Strong Soil (*Brampton*).—The soil may be improved by ridging it in the autumn and breaking up the ridges two or three times during the winter when they are crusted with frost. Ashes and gritty matter of any kind should also be mixed with it in as large quantities as can be obtained, and the soil will in due time be improved considerably. Such soil generally suits Cabbages, Broccolis, Kales, Savoys, &c., well; also Broad Beans, Beans, late Peas, Rhubarb, Strawberries, Raspberries, and bush fruits generally, but special care is needed in sowing and planting so as to enable the crops and trees to obtain a good start. This work must only be done in fine weather, the soil in contact with the seeds and roots being made as fine as possible. Soot is a good manure for such soil.

Earwigs Infesting Climbers (*W. A. T.*).—These pests can only be successfully dealt with by trapping, than which for your purpose few things are better than Broad Bean stalks cut into lengths of 5 or 6 inches, and placed horizontally in different parts of the trees or plants. The hollow stems of Hemlock, Snufflower, and Jerusalem Artichokes are equally applicable. The traps should be examined every day and the earwigs blown out into scalding water. Earwig traps, which may be had of most nurserymen, will prove effectual if well attended to. The climbers may be syringed with a solution of soft soap, 2 ozs. to the gallon of water, adding a pint of tobacco juice, which will make the plants distasteful to pests but will not kill them. Perseverance in trapping is the only remedy we know of. Syringe the ant-infested Begonia in the evening with Fir-tree oil insecticide, half a pint to six gallons of water, and repeating the syringing occasionally as is necessary. There are probably some insects on the plant which attract the ants.

Hardy "Red" Passion-Flowers (*Idem*).—*Passiflora carulea* var. *rubra* has reddish flowers, and it is quite as hardy as the species. *Comte Nesselrode* has reddish flowers, and succeeds in a warm situation with protection in winter; indeed most of the greenhouse kinds succeed against a wall with a south aspect when they are protected in severe weather.

Garden Roses (*B. D.*).—*La France*, *Gloire de Dijon*, *John Hopper*, *Duke of Edinburgh*, *Jules Margottin*, *Souvenir de la Malmaison*, *Baronne de Rothschild*, *Cheshunt Hybrid*, *Général Jacqueminot*, *Dupuy Jamain*, *Sénateur Vaisse*, *Alfred Colomb*, *Marquise de Castellane*, *Madame Victor Verdier*, *Marie Baumann*, *Charles Lefebvre*, *Boule de Neige*, *Exposition de Brie*, *Prince Camille de Rohan*, *Marie Finger*, *Céline Forestier*, *Beauty of Waltham*, *Abel Grand*, *Marie Rady*, *Dr. Andry*, *Mrs. Bosanquet*, *Capitaine Christy*, *Madame C. Joigneaux*, *Victor Verdier*, *Annie Wood*, *Mons. E. Y. Teas*, *Marguerite de St. Amand*, *Comtesse d'Oxford*, *Louis Van Hontte*, *Etienne Levett*, and *Camille Bernardin*. All of them will succeed on their own roots, but you will obtain better plants from nurserymen worked on other stocks.

Boilers for Heating Vinery (*B.*).—A riveted saddle boiler 24 inches long with arch inside 14 by 14 inches, outside measure 22 inches in width and 18 inches depth, is calculated to heat 450 feet of 4-inch pipe; but we should have the next size larger, or 30 inches long, inside of arch 16 by 16 inches, and outside measure 24 by 20 inches, as it is better to have sufficient heating power than too little, as with the latter sharp firing must be resorted to, and there is a great waste of fuel. A new boiler will do wonders when first set, but after a time becomes so coated with soot or other incrustation as to lose much heating power, hence the desirability of having a sufficiently powerful boiler, allowing a considerable margin for contingencies.

The White Beam Tree (*E. D. C. T.*).—The tree of which you require the name and uses is the *Pyrus Aria* of botanists, and is commonly known as the White Beam Tree, in reference to the white under surface of the leaves. It is a native of Britain, chiefly in the mountainous districts on limestone soils. Its fruit is acid and astringent, but is not disagreeable to eat when in a state of incipient decay, like the Medlar. When dried and reduced to powder, it has been converted into a sort of bread during times of scarcity both in France and Sweden; and when fermented it forms a beer, or, by distillation, a powerful spirit. It is greedily eaten by birds, for which reason the trees are ordered to be preserved in French forests, that the number of birds may be increased, in order to keep down the insects. The fruit also furnishes food to squirrels, and when it drops, deer and the hedgehog eat it with avidity. The wood is very hard, of a fine close grain, yellowish white, and susceptible of a high polish. It may be stained of any colour, and is much used in making handles of knives and forks, wooden spoons, and for musical instruments, and various articles of turneryware. The weed-like plant is *Chelidonium majus*.

Fruit-tree Leaves Discoloured (*L. M.*).—Red spider on the under surfaces of the leaves of the Peach trees is the cause of the yellow appearance of the foliage; but the insects are not very numerous, and are almost unpreventible on trees on walls during hot weather. Unless your trees were much more seriously affected last year than they are now insects have had nothing whatever to do with the barrenness of the trees. We are unable to state the cause of the slight discolouration of the Plum-tree leaves; excessive wet would cause it, or sudden and powerful sun after a period of dull weather. It will not in any way impair the fruitfulness of the trees. There are a few—very few—aphides on the under surfaces of the leaves, but they are not the cause of the discolouration referred to.

Grubs on Pear Tree (*M. F. S.*).—Your trees are attacked by the Pear sawfly, *Selandria æthiops*, which attacks the upper surface of Pear tree leaves during the months of July, August, and September. The description and habit of the insect are as follows:—The grubs are nearly half an inch long, cylindrical, but thicker towards the head than at the other extremity. The whole body, except at the time of skin-casting, is covered with a sticky, greenish black matter, and from this they have been named. Whilst feeding, the fore part of the body is so swollen that the vermin looks somewhat like a small tadpole. If the slimy matter is removed from the body this is found to be a grub or caterpillar with twenty feet, and of a pitchy brown colour. At the last-but-one casting of its skin the sliminess no longer appears, and the grubs become of a clayey colour. They finally form a brown cocoon about October, and remain in the pupa state until the following June or July, when the perfect insect comes forth. This fly is shining black, and the tips of the legs yellowish. The female lays her eggs on the upper surface of the leaves. The slime on the grub is of a peculiar nature, not being dried by exposure to the hottest sunshine. Dusting the tree with freshly slaked lime is the remedy for destroying these grubs.

Propagating Vines (*A Subscriber*).—If you take a piece of firm young wood after the leaves have fallen and cut it smoothly across just under a joint or eye, and shorten it to the eye above, and insert the cutting in soil either in a pot or in the garden, just leaving the top eye visible, that cutting will grow if the soil is kept at the right degree of moisture. The "eye" of a Vine is the bud that forms in the axil of the leaf. If the portion of the stem bearing the bud is cut out about half an inch above and below the bud, cutting from the back of the stem and slanting from the bud, then paring the bark off behind the bud, and insert the portion so prepared in light loamy soil in a heated frame in early spring, growth will start from the buds and roots from the wood, and a young Vine will be the result. We trust we have made the matter plain enough for you.

Names of Fruit (*W. B. Fisher*).—The Nectarine is the Boston, an American variety.

Names of Plants (*M. M.*).—The specimens are insufficient. If you will send others in a small box packed so as to arrive in good condition we will endeavour to name them. Sprays simply enclosed in letters generally arrive so much dried and crushed that it is impossible to identify them. (*M. H.*).—2, *Lysimachia vulgaris*; 3, *Silene Armeria*; 4, *Erigeron purpureum*. The other was too much withered to be recognisable. Send another specimen. (*A. Boyle*).—The specimen was much crushed by being sent in a letter, but it appeared to be *Briza maxima*. (*Rev. W. Ager*).—*Leycesteria formosa*. (*J. Boyes*).—1, *Thalictrum alpinum*; 2, *Monarda didyma*; 3, Unrecognisable; 4, *Lysimachia vulgaris*; 5, Much withered, but resembles *Eupatorium purpureum*; 6, *A. Verbasum*, but too withered for us to identify the species. (*Rhyl*).—1, *Chrysanthemum coronarium*; 2, *Lonicera tartarica*; 3, *Monochaetum sericeum*; 4, Quite insufficient for identification; 5, *Hypericum perforatum*; 6, *Sedum Ewersii*. (*A. B. C*).—3, *Eurya latifolia variegata*; 4, An *Adiantum*, but was too small a specimen to be identified; 1 and 2 were totally insufficient for recognition. (*K. A. H.*).—*Adiantum formosum*. (*W. Begbie*).—1, *Polygonum minus*; 2, *Senecio Jacobaea*; 3, *Medicago lupulina*.

POULTRY, PIGEON, AND BEE CHRONICLE.

ROTATION OF CROPPING FOR HEAVY OR MIXED LOAMY SOILS.

(Continued from page 151.)

We propose to further illustrate this subject by introducing a rotation upon certain strong soils to be found in various districts of the kingdom. The land has been cultivated, and permitted by both leases and custom to be so managed, in consequence of the land being made more valuable to both owner and occupier by a privileged system of cropping. The reason why we refer to it specially is because it is only permitted upon soils of unusual fertility and of proved capacity for producing valuable crops of corn and pulse in quicker succession than is common to strong soils. We will again take a farm of 200 acres of arable land, and refer to the rotation which we find has been in operation from time immemorial—viz., by taking alternate crops of cereals and pulse, with a long fallow made once in seven years. Under that arrangement 100 acres of Wheat or part Oats would be taken after a fallow; the following year crops of Beans, Peas, and Vetches would be taken upon 100 acres; and this is the old-fashioned system, by which it was reckoned that a higher rent could be afforded than by any other known rotation. Our object in proposing an alteration to some extent is to show the home farmer a plan of cultivation whereby he may obtain the full advantage of close cropping of saleable produce, and at the same time largely provide food for cattle.

We therefore propose to autumn-fallow by steam power 100 acres as soon as the land is cleared of the Wheat or other cereal crops.

Such soils as we now have under consideration, unless by great neglect, are not troubled much with couch, but oftener with the water grass, which roots only on the surface. In consequence surface culture is only required and the grass and weeds being removed, after which it may be ploughed and lie exposed for the winter months. If, however, the land is a perfectly clean corn stubble winter Beans and winter Vetches may be grown, either separate or mixed; but as this will only apply to a portion of the pulse line we shall treat it as the exception, and refer to the mode of cropping we propose after the land has laid fallow during the winter. As we have 100 acres to crop we propose that 20 acres should be sown with Broad Clover and Giant Saintfoin in the Wheat or Oats; 20 acres to be sown with winter Beans and Vetches mixed if the season is favourable, otherwise in the spring; 20 acres to be sown with Early Mazagan Beans at 30 inches apart in the lines and summer tares mixed; 20 acres of Beans of the ordinary Tick variety and Partridge Peas mixed; and 20 acres Early Mazagan Beans planted at 4 feet apart between the lines, and a line of Mangold between. This double culture of roots, such as Cabbage, Kohl Rabi, Mangold, or Belgian Carrots, may be extended by removing the tares or Partridge Peas from the seeding, because they would spread their haulm across the intervals and injure the growth of roots. Now, this rotation offers the opportunity for the home farmer to grow a large crop of roots as well as pulse crops, for we consider Beans are an uncertain crop, and therefore we grow either tares or Peas with them, or otherwise root crops at intervals, thus never trusting entirely to the Beans alone. After the Beans and other pulse and root crops are removed the land should be scarified by steam power, surface-cleaned, and manured for Wheat, or part Oats, either with yard dung or artificials according to the season. The 20 acres of Clover lea after having borne a crop of hay and seed, or two crops of hay, will come in for Wheat or Oats, whichever may be advisable in accordance with the season or other circumstances. Under this rotation we have 100 acres of either Wheat or Oats, and 100 acres bearing a crop of Clover hay or seed, a mixed crop of Beans and Peas, and a mixed crop of Beans and roots grown in various proportions, according to the requirements of stock and the extent of grass land attached to the farm. Before leaving this rotation we beg to say that we have often grown 25 tons of Mangold per acre, and Cabbage &c., in the same proportion in the intervals between the rows of Beans; and for further information on this subject we refer the reader to the article on the cultivation of Beans dated March 13th, 1879, in this Journal.

There is one more system which is exclusively applied to strong land; it is, however, at present an exceptional one, and we allude to the practice of continuous corn-growing as carried out by two gentlemen—viz., Mr. John Prout of Sawbridgeworth, Herts, and Mr. Edward Middleditch of Blunsden, Swindon, Wilts, who have each helped materially to solve some of the difficulties of clay farming. Mr. Prout, who was the first to attempt the system commenced in 1862, and has continued it up to the present time, and the only deviation from the growth of corn crops has been a few acres of Mangold, Cabbage, and Clover, and occasionally a few acres of Italian Rye Grass or tares. This, however, does not interfere with his general system of corn crops, and it may do so in a still less degree by laying down a small portion in permanent grass or Lucerne; we will therefore consider the subject as headed above has been practically shown to have grown cereals profitably on the same land for a number of years successively, and continued yearly by disposal of the whole produce, including straw, upon the land by auction on the eve of harvest. We wish the home farmer to understand that these striking results have been obtained from cultivation by steam power and the application of artificial manures only. Now, this system was originally

conceived through the experiments of Messrs. Lawes and Gilbert, who for a long series of years have proved the possibility of growing the same kind of crops upon the same soil annually. We have in consequence introduced and taken notice of the practice of Messrs. Prout and Middleditch, for the purpose of removing all impressions from the mind of the home farmer as to the actual necessity of change of crops, unless it is to obtain some such advantages as the rearing and feeding of cattle and sheep on the home farm.

Having referred to the rotations adapted and applicable under varying circumstances to heavy and flat-lying soils we now propose to refer to the mixed loamy soils, which are usually undulating. We find clays as a subsoil varying from strong and tenacious to a mild and marly brick earth, with surfaces varying from a kind of sandy loam to a friable hazel loam. These soils, notwithstanding the strength of the subsoil, are capable of being cropped in a different way from table lands, as instanced by a farm we occupied for many years, which we cropped in rather a peculiar manner, with the twofold object of growing corn, pulse, roots, grass, &c., and to provide for a heavy stock, both of cattle and sheep. In describing the system of cropping pursued we will again take a farm of 200 acres of arable land. The cropping is, correctly speaking, a five-course; we will therefore take one year's cropping of the whole 200 acres in divisions of 40 acres each, as we used to crop and cultivate them. The first division consisted of 40 acres of Wheat grown after Clover lea, pulse, and root crops in part, which will be more fully described in the fifth division. The second division of 40 acres was cropped, 20 acres with Oats, either winter Oats or white Canadians, and followed by stubble Turnips sown between the shocks; and 20 acres of Oats and Barley mixed as drege corn, and succeeded by an autumn fallow. The third division of 40 acres, cropped 20 acres with Mangold after stubble Turnips fed off by sheep eating cake, &c., and 20 acres of Potatoes planted after an autumn and winter fallow. The fourth division of 40 acres, cropped with Wheat and part Lent corn, according to circumstances of the season, &c., 20 acres of Wheat after Mangold pulled off for box-feeding of cattle, &c., and 20 acres of Lent corn sown after Potatoes, which were sometimes sown with Turnips also as a double crop, the Potatoes being sold and the Turnips pulled off for feeding sheep and cattle. In the year 1860 the Potatoes proved a full crop, and the Turnips weighed 28 tons per acre. The fifth and last division of 40 acres cropped with Clover, pulse, and Turnips, &c.; 20 acres of Clover and Giant Saintfoin seeded in the Wheat, grown after Mangold, 10 acres of Beans and Peas mixed, or with Beans and roots as a double crop, and 10 acres cropped with Trifolium of three sorts, and part Vetches, all sown in autumn, and followed in the spring by Swedish Turnips, common Turnips, Cabbages, &c. In this five-course rotation the crops succeed each other during the five years in the same way as in the five divisions, excepting the alternation of Clover and pulse crops. And in this way the annual produce will be—of Wheat 60 acres, Lent corn 60 acres, pulse 10 acres, Clover 20 acres, Potatoes 20 acres, root crops 50 acres, and green fodder crops 10 acres. In conclusion it will be observed that not only a large acreage of sale crops are grown in this last rotation, but a large provision is made and secured for the feeding of cattle and sheep, and thus maintaining the fertility of the land, but also keeping the land clean by the constant work and cultivation, and quick succession of crops, giving the opportunity to keep under the couch and weeds at a little expense chiefly by forking out by hand labour.

WORK ON THE HOME FARM.

Horse Labour.—During the impediment to harvest work which has continued at intervals up to the time we are writing, the horse labour of the farm must have been various and of a jobbing character. Unless a favourable change takes place in the weather it will be impossible to continue the work of the reaping and hinding machine, because the Wheat cannot be cut and tied when the straw is damp or wet without risk of serious injury to the grain. These observations apply with equal force to reaping of any kind, whether by machine with hand tiers to follow, or by hand labour. In every case when corn is to be tied into sheaves whether of Wheat, Oats, or Barley, it should not be cut faster than it can be tied. The question of tying is of great importance, especially in a wet or showery harvest, for in case the corn is cut and tied at intervals whilst the straw is dry, and it is properly set up in shocks of a moderate size, only a portion of the grain can be injured. Laying out and spreading dung either from the farmyard or cattle boxes ought to be done during intervals of obstruction to harvest work. Stubble Turnips may now be sown daily as fast as the corn is cut, and as soon as the crop is set up in shock on one-third of the land the other two-thirds may be ploughed and sown with Turnip seed every evening, and finished off whilst the ground is soft and moist, leaving the other third whereon the crop is standing to be sown after

harvesting the corn. Sowing Trifolium should also be done immediately after the stubble Turnip seed is sown, for the slugs being the greatest enemy we have to fear, the sooner the seed can be sown the more likely it is to evade their depredations. Although the best way is to sow the Trifolium seed and harrow it in on the surface, yet this plan does not secure it against the slugs as well as shallow ploughing, for that disturbs the slugs. Ploughing shallow also gives an opportunity for dragging out any lumps of couch or onion grass which may be found. We recommend all three sorts of Trifolium to be sown—the early crimson blossom, the second early pink blossom, and the latest of all the perfect white blossom.

Hand Labour.—This will now consist principally of attending the harvesting of the different corn crops, such as setting up the corn into shocks as fast as it is cut and bound by the reaping and hinding machine, or otherwise, in the absence of machinery. Hand labour will be employed in cutting, tying, and setting-up, and this is commonly done by the acre, giving an opportunity for the men to employ their wives and families in assisting and earning more money to their common advantage. When the corn is too wet for cutting there will be hoeing and singling late-sown Turnips to be done; the mowing of second crops of Clover may be done at such times, and early in the morning whilst heavy dews prevail. Trimming the quickset hedges too may be done at intervals, especially in those cases where the borders and ditches have been cut, and the grass carried away for feeding cattle, pigs, &c., in the yards. Men should also be at work preparing straw and piling it away for use in thatching the corn and hayricks. We must again advise the home farmer to use every endeavour to obtain a man capable of thatching the ricks as a regular labourer upon the farm. Just at this time it will have to be decided as to what portion of the second growth of Clover shall be cut for hay or left for seed, and there are various circumstances likely to occur and too numerous to mention here which must eventually decide the question, and in this case the judgment of the home farmer will be necessary in deciding the course to be pursued. Shepherds will now require great caution in all districts where low-lying meadows or irrigated meadows prevail, because it will be dangerous to feed the sheep entirely upon such pastures only, and at the same time allow them to remain thereon at night time; for after the serious losses of last year by the fluke rot in sheep we advise that the grass land alluded to be not fed at all by sheep; but in case there is a necessity for feeding some parkland pastures even these are dangerous, unless the precaution is taken to give the sheep a liberal allowance of oilcake and cracked Beans, and allow them to retire for the night to an arable field producing Clover, Saintfoin, or the mixed grasses, or otherwise Vetches and tall Rape, or early Turnips, Cabbages, &c., with rock salt always within reach. This generous and mixed system of feeding, together with the dry land night quarters, will generally keep the animals sound, although whilst feeding a few hours daily in park lands they may possibly take into the system the entozoa or fluke egg. Let it be borne in mind that we cannot trust to this mode of feeding entirely if the sheep run upon grass land lately flooded, nor yet to the irrigated or low-lying meadows. Cattle now have abundance of grass feeding where the changes of pasture has been attended to properly. It is important, however, where grass may be short that the dairy cows may receive oilcake with advantage both in the milk and its produce, and with benefit to the pastures.

THE AMERICAN HARVEST.

VAST as was the cereal product of the States last year, it will be greatly exceeded this season, and the whole of the prodigious surplus over what the Americans themselves will consume is practically bespoken for the English market, for the intelligible reason that there alone can it be always sold at a price. This surplus is a very serious fact, of which mere figures give but a vague idea. In one of the interesting reports recently contributed by Mr. Victor Drummond, Secretary of the Legation at Washington, with respect to the industry and commerce of the United States, he quotes with approval the estimate of the New York Bulletin, that the surplus of American Wheat at the close of the present harvest may exceed the average requirements of Europe by from one hundred million to one hundred and fifty million bushels, and naturally enough he adds that this must produce exceptionally low prices for breadstuffs. The opinion thus given was committed to paper before the end of June, when the harvest prospect was as yet uncertain; but a month later served to enlarge the estimate. At the end of July we find an eminent New York firm calculating that the harvest of Wheat will represent a total of five hundred million bushels, or fifty million bushels more than the enormous yield of 1879; that the Oat crop also will largely exceed that of last year; and that Indian Corn may reach a yield of fifteen hundred million bushels. The surplus of Wheat available for Europe over and above what sufficed for previous years of average European harvests they put at two hundred and thirty-three million bushels. Now, the entire export of Wheat from the States in the twelve months ending the 30th of June last was in round numbers one hundred

and forty-two million bushels, and if we assume that the shipments for the succeeding twelve months are only on the same scale, we shall have above four hundred million bushels of Wheat of the new crop left for consumption in the States. But the States cannot consume three-fourths of this, so that we have a surplus of one hundred million bushels over and above the abnormally large total sent to Europe in the last twelve months. It is an excess upon an excess; the undisposed balance of 1879 crop being carried forward to swell the still greater excess of 1880. Without being disposed to exaggerate, it is difficult to avoid the conclusion that the United States will have fully two hundred and forty million bushels of Wheat to dispose of for export during the next twelve months—that is, thirty million quarters, or about a third more than the whole consumption of Great Britain. In other words, if our soil had not produced a grain of Wheat this year, and if all the rest of the world had not a bushel to spare us, the American surplus would feed this kingdom easily, and leave a few million quarters to spare.

It is a good prospect, as we before observed, for the home consumer, and a splendid one for the American grower, but it is unrelieved gloom for the English farmer. What, it may be asked, is he to do with American Wheat coming over to this country now at the rate of four hundred thousand quarters a week, and with a further accumulation in the States, which seems always growing, as a vast additional acreage of fertile land is annually brought under cultivation? The hitherto accepted ideas as to the price which would pay an American farmer must be revised by the light which this rate of productive growth throws on the whole question. Last year it was said that American Wheat could be profitably delivered in English markets for 30s. a quarter, but it is now believed that even so low a value as 25s. a quarter would not keep it back. It is entirely a matter of transport, but then facilities of transport are always increasing with new lines of railway; and vessels suitable for grain carriage across the Atlantic are fast being multiplied to meet the demand for them. Neither railway nor ocean rates of freight will ever, so far as can be seen, reach a seriously obstructive point, and, failing that contingency, the accumulated store must find its way to our markets in an ever-gathering avalanche. To the home farmer there is ample food for reflection in a crisis for which no agricultural authority from Hesiod to Arthur Young can, so far as we know, find an exact parallel.—(*Daily Telegraph*.)

ROYAL AGRICULTURAL SOCIETY OF IRELAND'S SHOW.

THIS has been held this year at Clonmel, and if the number of entries comparatively is to be taken as a criterion of success, success has certainly been achieved. In Derry the number was 387 in 1875; Cork, 674 in 1876; Galway, 493 in 1877; Dublin, 1200 in 1878; and Newry last year only 460; while Clonmel can boast of 930. To prevent bias very many of the Judges were English and Scotch, and they were unanimous in giving it as their opinion that as a whole the animals exhibited were very superior. This Show, and especially some features of it, owing to the past unfavourable seasons was looked to with more than ordinary interest both in Ireland and Great Britain, and it must be a matter of congratulation that there was no falling away. The unavoidable absence of the Lord Lieutenant, owing to the death of the Dowager Countess Cowper, took away one of the attractive features of such expositions; but the weather made amends, for it has been several years since we had such fine warm, very warm, weather here. The shade thermometer has ranged from 70° to 78° during the past four days, and to-day has attained the maximum of 82°, which was on no day paralleled last year. This added immensely to the gala appearance of the Show, which was largely attended, and the amounts received for admission must have been considerable, as a charge of 1s. was made for admission to the jumping ground, 2s. 6d. to the grand stand, besides 5s. the first day, and 2s. 6d. the second, and 1s. the third for entrance. The Aylesbury Dairy Company had a large allotted space in conjunction with the Show too, and for which 1s. special charge was also made. This had much interest for the farming class, as this is a noted dairy district; but many thought for the sake of the humbler farmers, and their wives and daughters, that no separate charge should have been made. Among the rest Canon Bagot, who brought the Irish contingent to Kilburn last year, expressed this opinion to me, but said the local Committee were responsible. As your readers generally would neither be interested in details of the various breeds of stock or the prizewinners in the several classes, I shall only extend this notice by referring to the farm produce and a few other details briefly. Seymour Mowbray, Esq., Killeary, Mountrath, obtained the splendid cup presented by W. & H. M. Goulding, manure manufacturers, Cork, and the Society's first silver medal, for a very fine collection, containing several varieties of almost all the usual crops grown on the farm, including forty fine varieties of Potatoes, the following being the principal:—*Red-skinned*: Kerr's Red Champion, Surprise, Early Rose, Brownell's Beauty, American Chiles, Grampion, Early Redskin, Flourball, &c. *White*: Porter's

Excelsior, Woodstock Kidney, Schoolmaster, Snowflake, Magnum Bonum, Victoria Seedling (Paterson's Victoria), Flounders (very generally grown as early kind in Ireland), Ashleaf Kidney, American Prolific. *Blue-skinned*: Skerry Blue, American Purple, Scotch Blue. *Purple-striped*: Dons, Oneida (very curiously marked), Peach Blow (said to be a very good late variety). The largest Potatoes were Bresee's Peerless, which I am told is very largely grown in Canada, and forms the staple crop. If free from disease and suitable for table use it should be largely grown in Ireland. The latest variety shown was Scotch Champion. The second-prize collection was furnished by J. D. Paul, Esq., Ellenfield, Drumcondray, and to this was attached the fine challenge cup presented by Messrs. Sutton & Sons, Reading. This had some wonderful roots, especially Mangolds, which some thought could have hardly attained their dimensions this year. The farming class were much interested in a self-binding machine, made and sent by the Toronto Company.—W. J. M., Clonmel.

HARVEST DATES IN BERKS.

MR. T. OWEN of Clapton Farm, Hungerford, has written as follows:—"So much having recently been said and written as to the lateness of the crops and the harvest prospects, I have from my diaries compiled a table which may be interesting just now, as it shows at a glance the dates on which I have commenced reaping, and also finished harvest, each year from 1819 until 1878. The dates, which are thoroughly accurate, show that in twenty-six years I began reaping in July and thirty-four years in August, July the 15th being the earliest date and August the 27th the latest. In twelve years I finished in August, forty-two years in September, five in October, and one in November."

Memorandum when reaping Wheat commenced and when harvest finished on Clapton Farm (containing 600 acres of arable land) from 1819:—

ARTIFICIAL INCUBATION.

IT is now some time since we devoted several articles to the question of artificial incubation regarded from an historical point of view. Our object in collecting indisputable facts concerning its successful employment in times past, was to show that there was considerable *a priori* probability that in the future it might again be made of practical use to poultry breeders on a large, if not on a small scale. Pretty nearly all the well-authenticated cases of success had been on a large scale, and this left a doubt in our minds whether on a small scale it would ever be found to advance beyond the amusement of the fancier. At the time we did not follow up our general survey of these cases with any practical observations on the present methods of so hatching eggs. We are always unwilling to trust solely to information received from even the most trustworthy sources. We had no practical experience, but promised to publish the results of any which we might gain in the future. We have now personally managed a moderate-sized incubator with fair success during more than two months, and therefore think we may redeem a part at least of our pledge. Our wish had been to invest in a machine from each of the great incubator manufacturers, and to give them fair trials entirely under our personal management. We did not propose to publish the tabulated results unless some one incubator proved

itself incomparably superior to the rest. We know that many slight accidental circumstances which may easily be overlooked greatly affect both the register of temperatures and the general result; and it therefore seemed to us that the opinion of an unbiassed mind upon the merits and demerits of each incubator would be more valuable than published registers of their temperatures, in that a person who constantly watches them can make allowance for such accidents more fairly than their effect could possibly be explained. At present, unfortunately, from various circumstances, the chief of which was the inability this year to command a sufficient supply of water for hydro-incubators, we have tried but one. We shall not mention the name of the maker lest we should seem to advertise one machine before giving others a fair trial. It is an incubator, the water in which is heated by a lamp. It was in action about ten weeks, and almost the whole time under our own personal care. We had therefore full opportunity of making a few general mental conclusions, which it may not be useless to relate.

The first was, that while it was kept at as nearly as possible the generally received proper temperature—viz., about 102°, the eggs which hatched did so long after their due time—viz., at from the expiration of from twenty-three to twenty-five days. We subsequently kept the temperature at about 106°; the result was much better, and the time of hatching more normal. We found it best too to maintain this heat up to the last; when we lowered it chickens died in the shell which had already been heard to chirp strongly; when we kept it up weakly chicks seemed to receive a stimulus which helped them to come out.

Secondly, As to the question of moisture. We have all heard much of the absolute need of moisture, but we think that only those who have had practical experience of artificial incubation have any idea of the immense amount of moisture required—viz., that the eggs should be kept perpetually steaming. Certainly the spring was a remarkably dry one, but our incubator was in a decidedly damp place, partly underground. We began by keeping a trayful of earth perpetually moist underneath the eggs, and by damping them twice a day with tepid water. This was by no means sufficient; the greater portion of our first batch of eggs had perfectly formed chickens in them, but which died from either inability to break through the skins of the egg, which were almost as tough as casings of thin kid. We subsequently kept a large bath sponge in addition in a large earthenware saucer in the midst of the egg drawer; twice a day we filled the saucer with water. The sponge touching the hot cistern above caused so much evaporation that after twelve hours the water was often exhausted. The per-centage of chicks dead in the shell was then much less; still many so perished, and the eggshells of those which came out revealed the membrane still dry and harsh, and utterly different from those hatched under hens.

Thirdly, As to the much-debated point of the addition of more eggs during the time of incubation. We frequently added them, and so cannot fairly estimate the effect which the addition had upon the general success of our attempt. We are disposed to think that no great harm was done by it from the comparison of the results when eggs were more frequently and less frequently added; but this we noted, that in our machine, calculated to hold one hundred eggs, after the addition of thirty fresh eggs it was impossible to get up the average temperature within twelve hours. This must necessarily do some harm, which might, however, be much lessened if not obviated by the fresh eggs being warmed beforehand. This suggestion is not original, but one which we lately saw in the pages of a contemporary from the pen of one of our greatest authorities on the subject.

Fourthly, It is often inquired why so many chickens hatched in incubators come out cripples. The chief cause of this we believe to be the difficulty, already alluded to, of supplying sufficient moisture to the eggs. We closely watched many chicks during the process of self-extrication from the eggs; where the membranes were tough and hard it took a very long while, during all which time the legs were unnaturally cramped up after they ought to have been free—from this in some cases they never recovered. We believe that the struggling chick uses its hock joints much while twisting itself round in the egg, and for the final struggle to burst out of the shell. We observed many of our incubator-hatched chickens with hock joints largely swollen and purple with bruises.

Fifthly, Our experience coincided with that of other careful experimentors in incubation, that only those eggs can be at all depended upon to hatch well when artificially incubated, which in any case would be thought the most certain—viz., those lately laid, and those from vigorous birds, where few hens are allotted to one cock. To put in eggs which have been laid long, or which have travelled far, or which come from weakly parents, is abso-

lutely useless. To such the natural hen seems to supply some deficiency in a way which we cannot explain, and which is hardly likely to be artificially attainable. The time of year may seem a strange one to recur to incubators, but we would add one more piece of advice—viz., that those who wish to work them with success in the winter should procure them in good time, and thoroughly master their management in the autumn. We do not believe that any amount of care and intelligence can make it safe for a novice to put valuable eggs into an incubator within ten days of the time it is started. A month is a short time in which to study the various influences, atmospheric and others, which affect it, and to attain anything like proficiency in counterbalancing them.—C.

FOWLS DUSTING.

As most of the chickens hatched in 1880 are now become large birds, many runs are more crowded than early in the season; and this, combined with the hot weather, always favours the increase of vermin on the birds unless extra care is taken to prevent this from occurring. No plan we have tried is so good for keeping the birds clean and healthy as allowing them a good dust bath. There are various ways of making this, and also different ways of making them take to it. Briefly, it may be said, nothing is so good for the purpose as dry powdery ashes, taken from the ashpit before they have been wet, and put under a cover of some kind to prevent them from becoming so. One bushel or so of dry ashes will do for a dozen or more fowls dusting in for a considerable length of time, and when a little powdered sulphur is shaken over the heap occasionally it makes it sweeter and more effective. There is something, too, in the manner in putting down the ashes. We have had dry ashes lying under a dusting shed for a month or more without a bird attempting to take a roll in it, and all for the simple reason that the ashes were spread out level and not laid in a heap. When the same ashes were thrown up into a round mound there was a crowd round it in a short time scratching, and before long nothing but an intricate rolling mass of hens' tails, wings, heads, and feet. It is a curious circumstance, which I daresay many besides myself will have observed, that some fowls have very little inclination to scrape on the level ground, but as soon as an elevation of any loose matter is placed within their reach they go into it with energy, and this always induces fowls which are backward in dusting to pass through the cleansing process.—J. MUIR, *Margam, Taibach, South Wales.*

VARIETIES.

THE WHEAT CROP IN AMERICA.—A recent number of the *New York Tribune* states that "reaping will begin this week in central Minnesota, and it is now believed by well-informed persons that the yield in that State will reach 35,000,000 bushels, if no extended injury should be sustained within the next six days. One week ago, with over 60,000,000 bushels of the crop still in doubt, it was thought improbable that the aggregate yield would be reduced below 450,000,000 bushels. The probability now seems to be against a yield of less than 470,000,000 bushels, and competent statisticians maintain that, unless the weather during the next week causes serious injury, the yield will exceed 490,000,000 bushels."

— **THE PRICE OF MEAT.**—Mr. G. A. Haig, of Pen Ithon, Radnorshire, points out, in a letter to the *Times*, that in spite of the importation of American meat, the price of meat is as high now as it was five years ago, when not a word was said about "agricultural depression." He says:—"I have before me at this moment the *Agricultural Gazette* for July 21st, 1879, and for July 18th, 1874, and I find the quotations per stone of 8 lbs. in the Metropolitan Cattle Market to be as follows:—1879, best Scots, Herefords, &c., 5s. 8d. to 6s.; 1874, 5s. 6d. to 5s. 8d.; 1879, best shorthorns, 5s. 6d. to 5s. 8d.; 1874, 5s. 4d. to 5s. 6d.; 1879, second quality beasts, 4s. 4d. to 5s.; 1874, 4s. 4d. to 5s. So that beef at present is positively dearer than it was this time five years ago."

— **PREVENTION OF POTATO DISEASE.**—The well-known writer, Captain Mayne Reid, has been experimenting with Mexican seed Potatoes at his residence near Ross, thereby doubling his crop and entirely escaping the blight which has been so fatal to the English and Irish Potato crop of late years. He says that for the last three years he has been cultivating seed which came direct from Mexico, with the same result that, while ten other sorts, planted in the same

field, and tended with like care, have all been more or less diseased, his Mexican "papas" show not a spot of the blight. Nor is this all in their favour; for, while the best of the other kinds have yielded less than five tons to the acre, they have produced over ten in common drills done by the plough. Hundreds of specimens were above 1 lb. in weight, some even $1\frac{1}{2}$ lb. After being stored in ordinary field pits through the winter, the Mexican Potatoes come out perfectly sound, and seemed to improve in quality as the season advanced. As an article for the table Captain Reid thinks they have no superior; and he proposes the Government take in hand the importation of Mexican and Peruvian seed as a cure for the Potato blight.

— **THE HARVEST IN ITALY.**—A recent telegram from Naples states—Official harvest accounts after the heavy rainfalls report that the grain is in excellent condition. The Vines everywhere are most promising. There are good prospects for Hemp, Olives, and Beetroot. Only Maize is deficient on dry soils.

— **DAMAGE TO CROPS IN THE MIDLANDS.**—The recent storms and inundations in different parts of the midland districts have done considerable damage to the growing crops. Whole fields of Oats are in some places laid flat upon the ground, while Barley and other crops have suffered in like manner. Farmers are again lamenting their misfortunes, and the brilliant weather that succeeded the storms cannot make the harvest profitable.

— **AN AUSTRALIAN SHEEP STATION.**—Sir Samuel Wilson has sold one of his pastoral properties in New South Wales, consisting of about 3,000,000 acres of land, leased from the Crown, together with about a quarter of a million of sheep and some hundreds of cattle and horses. The station was sold for ten yearly payments of £40,000 each, to Messrs. McCaughey. This station was bought five years since for less than £100,000. The magnitude of the area of the station may be better understood when it is known that there are over 1300 miles of wire fencing on the station, although only about half the area is fenced into paddocks, as they are termed, varying in area from 500 to 60,000 acres.

— **THE YORKSHIRE HARVEST.**—The continuation of unfavourable weather, says the *Leeds Mercury*, leaves now no doubt that the year will be another bad one for farmers in the northern and eastern districts of Yorkshire. The laid Wheat is nearly worthless, and that standing is seriously affected both with rust and mildew, with about a third of deficiency of ears in the ear. Barley is in much the same condition as Wheat, and the prospect is that the general yield will turn out a little better than "screenings." Potatoes are now displaying all the worst symptoms. Turnips have suffered terribly, and cannot be more than half a crop. Mangolds are likewise doing badly, being festered with green maggot in the leaf. The general look-out for the farmers is of a very desponding character.

— **HOP PROSPECTS.**—The *South Eastern Gazette* publishes a series of reports on the condition of the Hop plant and the crop prospects. Summarised they give the following results:—Had it not been for an extraordinary attack of mould, such as has not been experienced for more than half a century, the crop would have been an unusually good one; but as it is the earliest will probably prove almost a failure, while the later sorts, if the weather is propitious, may yield a good crop of fair quality. In Mid-Kent the weight per acre will vary considerably, and correspondents set it at from 5 cwt. to 10 cwt. In North Kent the yield is expected to be heavier. In West Kent the crop is estimated at from 5 cwt. to 10 cwt., while from the Weald the report gives it at 10 cwt. per acre. Passing on to East Kent we find the crop to be, as indeed it is elsewhere, in a most critical state, depending altogether on the weather of the next few days; if it proves favourable a good average yield is anticipated. In the large Hop-growing district around Ashford 6 cwt. will probably be grown on the average; some gardens will produce 15 cwt. per acre, and others will not be worth picking. In the Isle of Thanet the crop will be heavy. The yield in Surrey is put at from 7 to 8 cwt., and advices from Worcestershire and Sussex speak of a more satisfactory crop than was anticipated ten days since.

— **PRICES OF WHEAT FROM 1641 TO 1875.**—The following list which has been sent to us by a celebrated agriculturist, shows the years in which Wheat has been at any given average price per quarter (omitting odd pence) from 1641 to 1875:—

Price.	Years.	Price.	Years.
22s.	1687, 1743, 1744	53s.	1679, 1697, 1757, 1768, 1797, 1823
23s.	1654, 1706, 1732		1853, 1861
24s.	1745	54s.	1790, 1846
25s.	1767, 1733	55s.	1837, 1862, 1863, 1874
26s.	1689, 1702, 1705, 1761	56s.	1694, 1699, 1821, 1858, 1871
28s.	1750	57s.	1641, 1658, 1675, 1842, 1872
29s.	1655, 1731	58s.	1659, 1803, 1826, 1827, 1832, 1873
30s.	1686, 1690, 1691, 1723, 1734, 1738, 1742, 1747, 1754, 1755	59s.	1643
31s.	1653, 1719	60s.	1642, 1693, 1698, 1828
32s.	1666, 1667, 1703, 1720, 1722, 1724, 1730, 1748, 1749	61s.	1644, 1674
33s.	1676, 1701, 1721, 1737, 1760, 1779	62s.	1661, 1804
34s.	1718, 1739, 1746, 1751, 1762	63s.	1696, 1824, 1868
35s.	1688, 1683, 1700, 1736, 1759, 1780	64s.	1830, 1838, 1841, 1867

— **NEW WHEAT.**—New Wheat has been offered at Colchester, Dorchester, and other markets, and the samples not being very firm only 48s. per quarter could be obtained for the produce.

COMB FOUNDATION.

A COMMUNICATION from your correspondent "B. & W." which appeared in a recent issue of the Journal induces me again to take up my pen on the subject of comb foundation. First let me say that there is one reference to my former letter which is misleading—viz., "After seven years of comparative failure he at last attained to that perfect success." Now my letter has reference to only three years of experiment with comb foundation, the seven years previous with guide combs, which were a failure. I distinctly stated that my first experience with Raitt's or any deep sheet of foundation was in 1878, and that from the first I have had but one breakdown and no crooked combs or curled corners.

Now, without the slightest expectation of earning the enviable name of "benefactor" to my apiarian brethren, I have much pleasure in giving my simple *modus operandi*, whatever it may be worth. First, the groove in the top bar of my frame is one-eighth of an inch deep and wide, cut with a plough plane. Second, a piece of lath half an inch square and long enough to fit so tightly across the frame as to bear the weight of the foundation when it is laid on it. Third, to prevent curling I drive two tin points (such as we use in fixing glass in outer sections) into the styles or upright ends of frame about $1\frac{1}{2}$ inch from the bottom bar and one-eighth inch apart, so that the foundation may hang loosely between them. The frame being thus prepared I cut the upper edge of the foundation to the exact shape of the under or grooved side of the top rail, so that when laid in the groove it shall lie evenly and closely along it. I then lay it on the crossrail between the points and in the groove, and, inclining the frame so that the foundation may rest against the crossbars, I pour in boiling wax, filling and slightly overflowing the groove. When cool turn the frame, and the ends being supported by the points the centre needs only a finger to secure the foundation from suffering from being put out of the perpendicular to wax the other side. All that is to be attended to after this is never to put the frame out of perpendicular unless while the foundation rests against the crossbar, which a slight touch will remove while holding the frame perpendicular when putting it into its box hive, and giving all possible ventilation below and above for twenty-four hours after hiving a swarm. I use, instead of quilt or board, only a strainer cloth on the top for that time, which allows the excessive heat which attends swarming or other excitement to escape in some measure. I deem this of great importance.

Having now as requested "plainly and minutely described"—

I fear with much prolixity—my system of foundation-fixing, I venture to give an instance of the tenacity of comb foundation when well fixed which occurred early in last June in my apiary. I was removing some frames of comb filled with honey to make room for brood, replacing those taken by foundation. On removal of my veil I found that one of the frames was filled with sealed brood and not honey, and accordingly I hastened to restore it to its place; but on taking up the frame of foundation which I had substituted for it I found it covered with bees, and in a moment of thoughtlessness I shook or rather jerked the frame to shake them off, with the result of twisting the foundation into the form of the letter S without in the least dislocating it from its attachment to the top bar, and by merely flattening it again gave it to another hive.

Now Mr. Cheshire and Mr. Raitt can answer for themselves why they have endeavoured "to strengthen foundation;" but it strikes me that the public craving for novelties on one hand, and the desire on the other of some material so prepared as to defy careless handling, may have some part in the matter; but I doubt whether either has experienced the failures your correspondent alludes to. I conclude by saying that I have had the satisfaction this week of having had my apiary inspected by Messrs. Abbott and Mr. Carr of Newton Heath, Manchester, who have seen all that I have stated as to the safety and perfect comb formation of Raitt's foundation, which is the only one I have written about. The above gentlemen have been in Clonmel conducting the bee department of the Royal Agricultural Society's Show.—GEORGE A. PROCTER, *Clerk*.

TENT OF THE BRITISH BEE-KEEPERS' ASSOCIATION AT CLONMEL.

THIS was one of the great attractions of the splendid Show just concluded here that had immense interest for everyone who knew anything of or had bees themselves, and in many instances for city folk, who perhaps never saw a colony of bees before, and who amused me by their curious questions, the principal of which had reference to their stinging propensities. I can readily imagine how your correspondent, Mr. Pettigrew, would have chucked over some of the queries, or would have enjoyed Mr. Carr's curious expedient for expelling young urehins who peeped in under the bee tent by taking a handful of bees and depositing them on their heads. Clonmel was to be the first introduction of the bee tent in a tour through Ireland from London, but by some curious mischance the "cockneys" sent in charge went astray, and so far neither has turned up; but Mr. Carr (lecturer) and Mr. Abbott (operator) were not to be discouraged, so they procured stocks from a noted bee man of the locality, and all went well. A "Cyprian queen" was telegraphed for, and arrived in an oblong box attended by some of her satellites, who, we understood, fed her on the way. One of the most interesting experiments performed, and indeed the principal object of the Bee Association, was to show how a colony of bees could be removed from a hive and transferred to a new one (or if late in the year located and fed with another colony) without having recourse to the barbarous custom of "smothering" with sulphur. This was done by a little smoke introduced among the bees—any smoke would do—and the hive gently tapped until the occupants moved out into a skep placed over it, or into another hive of the present year's swarming. When asked if the two queens would live together he said the stronger would be proclaimed empress, and the weaker killed and expelled. After many interesting experiments, and showing the fearless way bees may be dealt with, the method of extracting honey from the combs, and much valuable information, thousands of visitors were deeply interested.—W. J. M., *Clonmel*.

OUR LETTER BOX.

Lime for Preserving Eggs (*W. P. B.*).—The term "shell," as applied to lime, merely signifies that the lime is not slacked or in a state of powder, but is in lumps, and then widely known as shell lime. The "two shells" of lime might be read as two lumps, which of the ordinary size, weighing say about 1 lb. each, are more than 4 gallons of water can absorb, and twice the quantity would not make the lime water any stronger. The recipe we published is of proved efficacy.

Dark Comb (*M. B. D.*).—The dark colour of the comb is the result of age. We presume you do not find the new comb of this season of the same dark colour.

Bees—Various (*Tom*).—In reply to your queries taken in order, we have to say—1, An entire comb, "all capped honey," taken from the centre of a first swarm is not an unusual thing in fine seasons at this time of year. This year there has been a glut of honey in many parts of England, and after midsummer, when this occurs, bees will sacrifice everything to the paramount duty of providing room for their winter stores. We have known them clear away eggs and brood to make way for honey. 2, Your plan is a good one; nor is there any reason why you should not treat all your hives in this manner. If we mistake

not this will be the common practice in all well-managed apiaries in the future—a mark of "high farming" in bee matters. Take all the honey when a good price can be got for it, and supply its place with sugar syrup. 3, In this case we do not advise your trying to rear the stock in which the bees have been dwindling all the summer, even though they now have a breeding queen, unless you strengthen them largely by the addition of one or more lots of bees saved from the brimstone pits. 4, There is no objection to your feeding-on now such of your hives as you wish to fill with comb, especially if you supply them with bar frames and comb foundation. Feeding now will also stimulate present breeding. Perhaps we should prefer waiting till September.

Artificial Swarming (*Ten-years Subscriber*).—We should not advise you to disturb your bees at this season. The large quantity of bees that were outside the stock hive were no doubt driven out by the excessive heat of the last ten days. We have found this the case in our own apiary, where in every hive the bees hung out as if they were going to swarm. Your other question shall be answered next week.

Bees Attacked by Wasps (*S. W.*).—If the hive be still populous the bees will probably hold their own, by your simply contracting the entrance so as to admit of the passage only of a single bee. If it be weak, the entrance should also be contracted, but the attack should be eluded by removing the colony to a new situation at a distance of not less than a mile and a half. In a few weeks the autumnal frosts will probably rid you of the plague of wasps, and then the persecuted bees may be restored to their original position.

Feeding Driven Bees (*Lxx*).—If you do not mind the trouble and expense of the copious feeding necessary to enable the bees to furnish their hives with combs, and store these combs with food before winter, you may do as you propose. You had better permit your old stock to swarm next summer, and unite it to the swarm by driving in the autumn, or drive and unite the bees to another stock if you are desirous of breaking it up at once.

Kerry Cows (*J. H. B.*).—We believe the price of the cows you refer to in your letter varies according to the condition of the animal. Those in calf with first calf are £14, and those in milk after first calf £15 on the average.

REMARKS.

8th.—Stormy morning, with heavy showers and occasional glimpses of sunshine; fine bright afternoon and evening.
9th.—Fine bright warm day with pleasant breeze.
10th.—Fine, bright, and hot; almost unbroken sunshine the whole day, but pleasant breezes.
11th.—Fine, bright, and hot, but a good deal of cloud in afternoon and evening.
12th.—Beautiful summer day, sunshine a little broken by cloud in afternoon.
13th.—Cloudy and dull till about 11 A.M., afterwards fine, bright, and hot.
14th.—Dull morning, fine bright afternoon, cloudy evening.
A week of fine summer weather, the heat mitigated by pleasant breezes. Temperature considerably above that of last week, and higher than that of any other week this year.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 18.

THERE is no quotable alteration in the trade since last week, and trade remains quiet.

TOMATO CULTURE.

THE Tomato has long been cultivated in the gardens of the richer classes, but not to any great extent, and in the majority of cases the only attempt to secure a crop consisted merely of raising plants and planting them at the base of walls. If they succeeded, so much the better ; and if they partially or completely failed, then Tomato sauce had more or less to be dispensed with. A complete revolution, however, is being very rapidly effected, and not only is it incumbent on those in charge of large gardens to maintain a supply of good fruit, but the owners of smaller gardens, amateurs, and even cottagers, are also acquiring a taste for Tomatoes. This, in my opinion, very satisfactory state of affairs, may be accounted for in several ways, the most important probably being the undoubted superiority of the varieties of modern introduction, more especially those of American origin. These are particularly good eaten as a salad in an uncooked state, and, much as some epicures may like Tomato sauce, they will dispense with this rather than the salad.

Many, owing to the uncertainty of the outdoor crop, are now turning their attention to the growth of Tomatoes under glass, and I see no reason why they should not so be grown in every garden with any pretence to the name. Room is found for and much time and trouble is spent over a crop of Cucumbers, which are really unwholesome ; or Melons, which unless well grown are very unsatisfactory ; then why not grow fewer of these and substitute Tomatoes ? They can be grown in frames much more easily than either, and if grown in houses are certainly more ornamental. By all means grow them in the open air as heretofore, regarding them as a supplementary crop, to be appreciated if a success, and, if a failure, not such an inconvenience as of old. At the present time I have a few fruits left on plants in a plant stove, a great quantity to follow these in a cool plant house—the plants in pots in both instances, a number of dwarf plants bearing heavy crops in a cold pit previously occupied with early Cauliflowers, more at the base of walls, and a number planted in a south border and trained up stakes. Neither of the two latter is affected either by the late dull wet weather or the disease, which is either the natural result of such weather, or, as savants have it, really the Potato fungus disseminated in the form of “spore-laden air sweeping over the earth.” This theory, however, has yet to be proved ; but if correct the question arises, Are there separate waves for both Tomatoes and Potatoes ? The latter are as bad as can well be, but we as yet hear no complaints about the former.

It is not my intention at the present time to refer at any length to any of the above crops, as they may advantageously be left to a more seasonable date, but I will offer remarks on the cultivation of Tomatoes during the winter that may possibly be of some use to the inexperienced.

Tomatoes are really of very easy culture, and are of a very accommodating nature—that is, they can be grown in a variety of positions, and if a few important details are closely observed success is certain in every instance. In the spring and summer they are grown here both in boxes and large and small pots under glass, and are either trained perpendicularly up stakes or wires at the ends of Peach and plant houses or vineries, thinly at intervals round the sides of a high plant house, or up the roof of a low plant house. I have also had good crops from plants trained to the back walls of a vinery, but in this instance the Vines had not filled the house, and care was taken not to crowd the plants. Bottom heat is not really necessary, but I like to have the earliest crops near the hot-water pipes.

Strong plants in pots in a cool house which is closed rather early in the afternoon have been stopped beyond the third cluster of fruit, and will now be allowed to make a single strong shoot near the top, to be stopped beyond the second bunch of bloom it will form. By the time these blooms are fairly set the first crop will be nearly or quite matured, and after some of the old soil in the pots has been removed, and a liberal top-dressing given, the whole batch will be placed in a plant stove, the temperature of which, although never high, is seldom allowed to fall below 60°. The pots will stand on a staging about 12 inches above the hot-water pipes, and the plants be trained up the highest part of a trellis at present occupied by Melons. To keep up the supply through the winter a number of plants obtained from cuttings which are now being struck, are grown on and trained-up the bared stems of the older plants, thus avoiding injury to the ordinary occupants of the rest of the staging, the plants being potted singly in large pots and arranged in one line only.

Plants raised from cuttings are not preferred to seedlings, but when strong well-matured growth can be obtained cuttings strike readily in a little heat and make good plants. My cuttings are taken from the tops of pinched-back plants, a little of the old wood being retained, as strong sappy shoots taken off without this precaution are apt to damp off. About five are placed near the sides of a 6-inch pot, in moderately fine soil. The pots are placed in a Cucumber frame, and the cuttings shaded slightly till rooted. They are then potted-off into 5-inch pots, and returned to the frame till established, and are then without delay well exposed to the sun on the front staging of a Peach house. Before becoming root-bound they receive their final shift into either 10 or 12-inch pots, the soil employed consisting of two parts of rough turfy loam to one of roughly chopped decomposed manure. A moderate amount of drainage is employed, and this is covered with the roughest of the soil. The plants are potted firmly and deeply, the pots being only about three parts filled to admit of a good top-dressing being given later on. On these young plants again I like to have a cluster of fruit set before they are placed in a higher temperature, but they are not left in the Peach house later than September, or a check to the growth is the consequence. One stem only is allowed wherever the Tomatoes are grown, and no laterals are permitted to form (an important detail not so

strictly observed by many as it should be), unless the plants are weak. In this case, especially if the plants have been for some time in small pots, the foliage is not sufficiently strong to swell the stems, and it is, therefore, advisable to allow the formation of laterals, these to be pinched back to one joint.

At the time the autumn-struck plants are transferred to the stove the top-dressing is given, into which the stems quickly emit numbers of strong roots, which will greatly assist the swelling fruit. By the time the third bunches of bloom are developed the growth will have reached the prescribed limits and is topped accordingly, and as the laterals or sub-laterals are kept rigorously rubbed out, the whole strength of the plants is thus concentrated on the fruit. They are never allowed to become dry at the roots, and liquid manure is given at each alternate watering. Some varieties, notably *The Trophy*, do not set freely either in heat or in the open air—not, I think, because the blooms are really barren, but on account of a scarcity of pollen. I never leave their setting to chance, but prefer impregnating the blooms with the pollen of commoner freer-setting varieties, such as *Keyes' Prolific* and *The Conqueror*. In the spring months, however, the central parts of the blooms when dry are gently rubbed together, each fruit thus being set by its neighbour. So well do both plans succeed, that to have good fruit I usually find it necessary to thin out the bunches. Forced fruits are apt to crack when changing colour. Dryness at the roots checks this but injures the later fruit; and the best plan is to cut them on the first signs of cracking, as they will ripen well on a dry shelf in the same house or temperature.

This season, probably, we shall have sufficient fruit from the open-air plants to carry us well on towards the new year, but they are of inferior quality, especially those cut in a semi-green state and ripened in heat, to those grown under glass, and will be handed over to the cook for making into sauce. *Trophy* and a variety evidently selected from it are mostly grown under glass here, as they are much superior with regard to shape, size, colour, and quality to any variety that I am acquainted with, with the exception, perhaps, of *Hathaway's Excelsior*. The latter is well adapted for culture in pots, and is preferred by some to the two former, and it certainly is particularly good for open air culture. In addition to these I am growing both under glass and in the open nearly every catalogued variety, and am in a position to discuss their merits, for the former work at all events.

Grown under precisely the same conditions as the rest, *Early Gem* was the first to ripen by about a week; it is a good cropper, but unfortunately the fruits are small. *Conqueror* is a very heavy cropper, growth sturdy, and the fruit corrugated, but otherwise good; *Earley's Defiance*, a superior form of the *Large Red*; *Dwarf Orangefield*; *Vilmorin's Dwarf Early*, a very dwarf, free-bearing, and improved form of the *Orangefield*, and a variety certainly deserving of general cultivation; *Ne Plus Ultra*, a vigorous grower, shy-bearing, and round-fruited; *Early Red* and *Large Yellow*. All commenced ripening at much the same time. The preference is given to the first, second, and fifth in this batch. Scarcely a week behind these are *Trophy*, *Stamfordian*, *Hathaway's Excelsior*, *Viek's Criterion*, *Aeme*, *Carter's Green Gage*, and *Hepper's Goliath*. About these I will only mention that *Viek's Criterion*, a somewhat small but very free-bearing variety, is particularly well adapted for culture in small pots, and that the principal merits of the *Green Gage* are its distinct colour and pleasing flavour. The small-fruited varieties are extremely ornamental, but otherwise comparatively of little value. Of those I am growing the *Cherry Red* and the *Burghley Pet*, both very prolific, round-fruited, and of pleasing flavour; *Dickson's Queen* of the *Tomatoes* has pear-shaped fruit produced in large clusters; *Nesbit's Victoria*, plum-shaped fruit, prolific; *Grape-shot* and *Sutton's Royal Cluster* represent an improved form of the *Red Currant*.—W. IGGULDEN.

CATTLEYA CRISPA.—I see mentioned in your paper a fine plant of *Cattleya crispa* at *Burston Rectory*, with sixteen flower spikes and eighty-four blooms. I have a plant now in flower with nineteen spikes, and 111 blooms, made up thus—two spikes seven each, twelve spikes six each, and five spikes five each. Un-

fortunately one other flower spike was broken off some three months ago. There are several of the old growths that have this year thrown up two growths, and are not strong enough to flower. I hope to see next year many more flower spikes. The plant grows in a basket 18 inches square, and is full of pseudo-bulbs, spreading out nearly 4 feet all round. I should say there are about 150 pseudo-bulbs on the plant, but I have never counted them carefully. It quite fills the house it is in with perfume.—B. DYMOND.

THE VINE TORTRIX.

ALTHOUGH there is no truth in the supposed adage that "misfortunes never come singly," the coincidences in trouble that do occur are sometimes remarkable. We have recently had to chronicle another appearance of the much-dreaded *Phylloxera* in these islands, and now we find that serious damage has been done to some Vines by the larva of *Tortrix vitisana*. This has, however, long been recognised as a British insect, but little is yet known of its habits by either naturalists or gardeners. It has been discovered upon the bunches, attacking these not for the sake of the fruit, which is pierced to enable the larva to reach the seeds. In habit it appears to be semi-social, and a number of them will spin loose threads upon the branches, upon which they pass and re-pass. Probably during its early life as larva the species feeds upon the leaves of the Vine. The chrysalis state is of brief duration, and the moth emerges in August. This is not, unfortunately, a conspicuous insect; it belongs to the section of moths popularly called *Bell moths*, because the closed wings resemble a bell. The expansion of the wings is about three-quarters of an inch. An important check to the progress of the species would be the removal or destruction of the eggs, which are undoubtedly deposited about this time, probably in small patches, however long they may remain unhatched. They might be placed either upon the leaves or upon the twigs, and should be searched for with assiduity. It has been generally thought that this Vine pest dislikes heat, and is therefore not likely to do much injury under glass; but we have recently seen a grand crop of Grapes in a very large vinery practically ruined by the larvae puncturing the berries and causing their decay. We have never known of a similarly violent attack of this insect, and we allude to it now for the purpose of directing attention to an insidious pest, which if it spreads cannot fail to prove highly destructive. Where the caterpillars are disturbed in the bunches, and they are not easy to find, they suddenly let themselves down to the ground by a slender thread and find refuge in the soil.

OLD-FASHIONED GARDEN ROSES.

NOTWITHSTANDING the prevailing rage for such varieties of Roses only as are deemed suitable for exhibition purposes there are, I venture to say, many rosarians who view with some considerable regret the gradual extinction of so many grand old favourites among the summer Roses. It is true that their individual blooms are not to be compared either in size or shape with the magnificent Hybrid Perpetuals of the present day; but in colour, and equally in perfume, summer-flowering Roses can well hold their own, while for vigour of constitution and profusion of bloom they certainly stand unequalled. It is more than probable that Roses of this class will, like the long-neglected hardy herbaceous plants, become fashionable again for garden decoration, as indeed they well deserve; but meanwhile we are losing sight of many varieties which ought to be preserved. Some time since I started a collection of old-fashioned Roses, but lost a large number in moving them to another residence; now again I mean to make the attempt, and invite all brother rosarians similarly interested to co-operate with me. I need hardly add that buds of scarce and really desirable varieties will be gratefully received and as freely given when possessed by me.

The following varieties are, I believe, still to be found in some of the nurserymen's lists, and should find places in most gardens of any extent, where they will succeed admirably, most of them, as pillars or tall standards, and will be found to produce, with a little care and attention and a minimum amount of pruning, an exceedingly beautiful effect. Among the section known as *French*, *Boule de Nanteuil*, *Kean*, *Cynthia*, *D'Aguesseau*, *Ohl*, and *Letitia*. *Hybrid China*: *Blairii II.*, *Brennus*, *Chénédolé*, *Comtesse de Laccpède*, *Fulgens*, *Leopold de Bauffremont*, *Madame Plantier*, *Magna Rosea*, *Général Jacqueminot*, and *Madeline*. *Alba*: *Félicité*, and *Madame Audot*. *Damask*: *La Ville de Bruxelles*, *Madame Hardy*, *Madame Zoutmann*, and *Leda*. *Hybrid Bourbon*: *Charles Lawson*, *Juno*, *Coupe d'Hébé*, *Paul Perras*, and *Paul Ricaut*. *Provence*: *Old Cabbage*. *Moss*: *Baronne de Wassanaer*, *Common*, the *Crested*, *Lancei*, and *White Bath*. *Austrian Briar*:

Persian Yellow; and lastly many beautiful *Climbers*, such as Bennett's Seedling, Madame D'Arblay, The Garland, Félicité Perpétué, Crimson Boursault, &c.

But where can we find old favourites such as the following, consigned, most of them long since, to oblivion by the published trade lists? Do any of them still flourish in an obscure nook of some rambling garden? If so, are they known by name? Not one of these have I been able to procure, though I would fain grow them all. *Hybrid China*: Beauty of Billiard (most glowing crimson), De Candolle, George IV., Belle Marie, Duke of Devonshire, Charles Fouquier, Marie de Champlon, and Gloire de Coulaine. *Hybrid Bourbon*: Charles Duval, Le Capitaine Sisolet, Hortensia (a somewhat single flower, colour salmon pink, with a very peculiar aromatic perfume), Glorieux, La Dauphine, Comte Boubert, Miss Chauncey, and Henri Barbet. *Hybrid Provence*: Princess Clementine (very beautiful white), Comte Plater, Comtesse de Segur, Globe Hip, and Rose Devigne. *French*: Aspasia, Gloire de Colmar, Napoléon, Telemaque, Triomphe de Jausens, Schombrunn, and Old Tuscany. Can anyone give me information as to these or other good old Roses? I shall welcome any correspondence on the subject, and hope at some future time to recur to it in these columns.—JULIUS SLADDEN, *Badsey, Worcestershire*.

ABOUT POTATOES.

THE state of the Potato crops throughout the country is always a matter of concern at this season of the year, the crop of the present season being no exception to the rule. The growth of the Shaws has been extraordinary as a rule, dwarf-growing varieties like the Regent rivalling the Champion of ordinary seasons, though this year these latter are far ahead of anything I have ever seen in the way of haulm growth. Regents are now full grown and a good crop; Victorias are also a good crop, but not quite finished yet, while Champions have much growth to make, and unless we have a downpour of rain it is not likely that the latter will swell off their crop at all, as the fields are very dry. I was inspecting some yesterday, lifting individual plants over the field, and already the disease has made a commencement on the Regents. This is attributable to two or three days of drizzling rain we experienced at the beginning of the present week, which laid the foliage and tubers at the same time open to the attack of the disease.

If the weather continues dry the progress of the disease will be arrested, but if wet supervenes then the crop will be decimated. And here we arrive at some of the so-called means for saving crops. One says, Lift as soon as the tubers are large enough, no matter whether the disease has appeared or not. Another tells us to draw the haulm directly the fatal spot shows itself, and the crop will remain secure in the earth. Others are of opinion that it is no use trying to save the crop by these means, it being far better to let the disease run its course on the tubers that have been tainted, and lift when the cold has put a stop to its ravages. There will doubtless be something to be said in favour of one and all of these systems, otherwise growers would not favour them. In the matter of the last-mentioned I have no personal experience, although it is the opinion of many practical farmers that it is useless to combat the disease or to lift the crop until it has done its worst, the taint of the disease otherwise making itself felt long after the Potatoes are clamped. This may be a mistake, but it remains an opinion practically backed up by pounds, shillings, and pence, by men whose income depends very greatly on the saving of their Potato crops. My own experience of the other systems is that they cannot be depended on to keep the crop clear. Every year our Potatoes are lifted directly the tubers are large enough in order to have the ground for other crops, and every year we find the disease appear after the crops have been lifted, though there may not have been the slightest appearance of it when lifting. I have had some varieties entirely destroyed, not even a remnant having been saved for seed; and these lifted before the disease was seen in the locality. The same thing is occurring this year. Some of our stocks lifted in the best apparent health in the first week of August are now becoming spotted. We have lifted others since which had the haulm removed at the beginning of the month; these have turned out perfectly free from disease, but I shall not be at all surprised when they are uncovered to find the disease amongst them.

The only Potatoes I find reliable are early kidneys; these never go wrong with us, though it must be noted that they are grown on a warm and dry border. Myatt's Kidney and Mona's Pride are the best croppers here. I grow a few each of a large number of varieties, but do not find any for main crops for gardens better than these two and the White Don. Doubtless other gardeners have their favourite varieties which suit their particular soils better than these.

And so it is perhaps in the matter of checking or stopping, or may be entirely frustrating the Potato disease. What may be successful with one grower may entirely fail under changed conditions. Anyway this is one of those subtle things which it does not do to dogmatise about. Let us try by all means every possible deterrent or cradicator of the disease, but do not be over-sanguine of success with any of them.—R. P. B.

SHROPSHIRE FLORAL AND HORTICULTURAL SOCIETY.—AUGUST 18TH AND 19TH.

THIS Society held their annual Show under much more favourable conditions than last year. The Exhibition on the whole was a great improvement upon those of past years both in the quality and quantity of the exhibits, and this without doubt is by far the best Show held at Shrewsbury under the management of the present Committee. It is scarcely necessary to allude to the excellent condition in which the plants were shown when it is stated Messrs. Cypher and Tudgey were competing for the principal prizes. In Mr. Cypher's collection *Erica æmula* was an excellent plant, the most profusely flowered example we have ever seen exhibited. The *Dracænas* shown by Lord Hill, Hawkstone (Mr. Pratt, gardener), were worthy of special note, also the table plants shown by the same exhibitor. The schedule contained twenty-seven plant classes, ten classes for fruit, and an additional prize of £10 given by Lord Hill for a collection of Grapes, and fourteen for vegetables.

Store and Greenhouse Plants.—In the class for twenty specimens, ten flowering and ten foliage, Mr. F. Cypher, Cheltenham, took the lead, followed by J. G. F. Williams, Esq. (Mr. Tudgey). Those staged in the first-prize collection were fresh, and on the whole larger than the others, Mr. Cypher's collection being very strong in flowering plants, and comprised a fine *Stephanotis floribunda*, well bloomed and about 5 feet through; *Erica Thomsoni*, well bloomed and 6 feet in diameter; *Anthurium Schertzerianum*, *Lapageria alba*, *Erica Irbyana*, *Bougainvillea glabra*, all good plants, the latter 7 feet in diameter; *Ixora Fraserii*, *Erica æmula*, and *Dipladenia amabilis* were all plants in excellent condition and profusely flowered. The best of the fine-foliaged plants were *Cordyline indivisa*, *Latania borbonica*, *Areca lutescens*, *Cycas intermedia*, *Gleichenia flabellata*, *Croton majesticus*, *C. Wiesmani*, and *C. Disraeli*, which were well coloured. The most noteworthy of Mr. Tudgey's plants were *Erica Uhria superba*, 6 feet in diameter, excellent; *Croton Johannis*, fine colour, and *Cycas revoluta*, *Latania borbonica*, *Cycas circinalis*, *Ixora coccinea*, *Croton Andreanus*, very good. In the class for nine plants, five in bloom, Mrs. Tuson, Abbey Foregate (Mr. Farrant), was first with fine plants of *Ixora floribunda*, *Erica Shannoni*, *Clerodendron Balfourianum*, and *Croton pictus*, this collection was rather weak in foliage plants; Lord Hill, Hawkstone (Mr. Pratt), being placed second, and was much stronger than his opponents in foliage plants, his best plant being *Nepenthes Hookeri*. *Croton Queen Victoria* and *C. Wiesmanii* were good, also *Alocasia metallica*. Sir T. Meyrick, Bart., Appley Castle (Mr. Warrender), was placed third with a small but even collection. In the class for six Cape Heaths, distinct, Mr. Cypher was again first with small well-bloomed plants of *Erica Vernoni*, *E. Irbyana*, *E. Austinana*, *E. Turnbulli*. Mr. Tudgey was second with larger but rather uneven plants, the best being *E. Uhria superba*, *E. tricolor*, *E. Eppsii*, and *E. ampullacea Williamsi*. In the class for six Palms, distinct, there were four exhibitors—Mr. Cypher being first with clean, fresh, and well-grown plants, such as *Kentia Fosteriana*, *Kentia canterburyana*, and *Cocos Weddelliana*. Mr. Williams second with much larger plants of *Kentia australis* and *Geonoma princeps*. Mr. Pratt third with neat specimens.

For six *Dracænas* Mr. Pratt was first with excellent plants of *D. regina*, *D. amabilis*, *D. Taylori*, *D. Baptisti*, *D. Mooreana*, and *D. Dennisoni*; second Mr. Warrender with small but neat plants of *D. Fraseri*, *D. Chelsoni*, *D. elegantissima*, *D. amabilis*, and *D. Baptisti*; Mr. Farrant being first for *Caladiums*, and Messrs. J. W. Pritchard & Sons, nurserymen, Dorrington, second. The prize for six *Coleuses* was well contested, and many of the plants were 7 and 8 feet in diameter. Messrs. Jones & Sons, Cotton Hill, were first; Mrs. Shaker (Mr. F. Morris) second; and G. D. Lees, Esq., Woodhill (Mr. J. C. Salter), third. *Fuchsias* were not well shown. Messrs. Pritchard & Sons, Lord Berwick (gardener, Mr. Pearson), H. Burd, Esq. (Mr. J. R. Jones), obtained the prizes in the order named. Mr. G. D. Lees obtained the only prize given for *Liliums*. In the class for six *Begonias* Rev. J. H. Charter, Severn Villa; Rev. J. D. Corbett (Mr. R. Milner), and Mr. E. Burd were the prizetakers with fairly bloomed specimens. In the class for six double *Pelargoniums* Messrs. Oldroyd & Co., Shrewsbury, were first with an even collection; Mr. Jones, Colom Buildings, second with good plants; and Messrs. Jones & Sons third with much smaller plants, but very neat. Six *Zonal Pelargoniums* Messrs. Oldroyd & Co. were again first; second Mr. J. R. Jones with good plants of Charles Smith, Lady Sheffield, J. Fellows; Messrs. Jones & Sons third, having good plants of Rev. F. Atkins, Master Christine, and Beauty of Wilts. In the corresponding class for three plants Messrs. J. B. Hudson, H. Owen, and H. H. Treasure were the prizetakers. The classes for *Achimenes*, *Gloxinias*,

and Balsams were poorly represented; Mr. R. W. Withers, Mr. B. Blyth, and Mrs. Shuker taking the principal prizes.

In the class for twelve table plants, pots not to exceed 6 inches, eight collections were staged, and the whole were good and much admired, Mr. Pratt gaining first honours with beautiful even plants about 8 to 10 inches high, some of the most noticeable being *Croton Prince of Wales*, *Aralia Veitchii gracillima*, *Dracæna Ernesti*, *Arceæ aurea*, *Dracæna Guilfoylei*, *Croton interruptus aureus* (a new light elegant form, recently sent out by Messrs. Ireland & Thomson, Edinburgh), *Geonoma gracilis*, and a well-coloured *Croton angustifolius*; Mr. Farrant gaining second prize with rather larger plants, the neatest being *Aralia Veitchii* and *Croton Wiesmani*. C. C. Coates, Esq. (Mr. Davies), was awarded the third prize. Messrs. F. & A. Dickson and Sons and Mr. Cypher were also exhibitors in this class.

For a collection of fifty miscellaneous plants in 5-inch pots, thirty in bloom. Six lots were staged in this class, and arranged upon staging 4 feet wide in the large plant tent. These collections were very effective, and excited much attention. Messrs. Pritchard & Sons were first with a choice assortment of Palms, Lilioms, Heaths, Coleuses, Ferns, Caladiums, Bonvardias, Fuchsias, Petunias, *Dracænas*, &c.; second Mr. H. H. Treasure (Mr. Cooper) with a similar assortment; Achimenes and Vallotas were most striking, Messrs. Pritchard & Sons secured the third prize.

Ferns.—These were not numerous, but really good specimens were exhibited. For nine exotic specimens Mr. J. Cypher was first with *Davallia Mooreana*, 8 feet through; *Alsophila elegantissima*, *Adiantum cardiochlaena*, *Cibotium regale*, and *Gleichenia spelinacea*. Second Mr. Williams, with fine plants of *Gleichenia rupestris*, *G. Mendelli*, *G. dichotoma*. Third Mr. Pratt, with good examples of *Adiantum amabilis* and *Nephrolepis davallioides*. For six exotic Ferns Mr. Warrender was first with plants about 5 feet in diameter of *Alsophila australis*, *Adiantum trapeziforme*, *A. formosum*, *Phlebodium aureum*, and *Microlepia hirta cristata*. Second Mr. Farrant, the most noteworthy being *Cyathea medullaris* and *Lomaria gibba*.

Miscellaneous exhibits were principally arranged in the large plant tent, and added materially to the general effect of the Show. Messrs. James Veitch & Sons, Chelsea, staged a most attractive group of plants, principally in small pots, including several Orchids in flower. *Rhododendrons*, such as *Princess Royal*; *Coleuses* were represented by G. Simpson, Mrs. Geo. Simpson, Dean Swift, and others. *Isolepis elegantissima* was also shown quite distinct, and an improvement upon the species. *Nepenthes*, *Crotons*, *Dracænas*, *Lilium auratum* dotted in the group, and many other valuable plants completed the collection. Messrs. James Dickson & Sons also staged an interesting collection of plants in 5 and 6-inch pots, including Palms, *Dracænas*, *Crotons*, and *Bertolonias* of the newest types. The same firm also showed a very fine box of *Roses*, not for competition, containing the finest blooms in the Show. Messrs. F. & A. Dickson and Sons, The Upton Nurseries, also staged effective collections of stove and greenhouse plants, and groups of choice shrubs in pots, with plants of *Lilium auratum*, and fine boxes of *Nertera depressa*, the plants crowded with their bright berries. Messrs. Pritchard & Sons also exhibited groups of plants, including Ferns, Achimenes, Caladiums, &c. Messrs. Oldroyd & Co. sent groups principally of Ferns, Palms, and small Zonal Pelargoniums in flower. Messrs. Jones and Sons, Cotton Hill, also staged similar groups.

CUT FLOWERS.—These were shown in quantity and in capital condition, especially the bouquets, Dahlias, Gladioli, and Phloxes. *Roses* were not very numerous, but in fair condition considering the lateness of the season. In the class for thirty-six, Mr. Griffiths, Hereford, showed good blooms of *Mdlle. Victor Verdier*, *Alfred Colomb*, *Niphetos*, *Belle Lyonnaise*, and *François Michelon*, and was awarded the first prize; the second going to Messrs. F. & A. Dickson and Sons, their best blooms being *Lord Macaulay*, *Marie Baumann*, *Mdlle. Marie Rady*, and *Charles Lefebvre*. For twenty-four blooms the successful exhibitors were Mr. G. H. Berrington, Ludlow, and Mr. W. Shaw, Blakebrook, the first-prize lot having good blooms of *Black Prince*, *Reynolds Hole*, *Niphetos*, and *Baronne de Rothschild*. For nine blooms Mr. Berrington was again first, Mr. C. Crump second, and Mr. G. Townsend third. For thirty-six Dahlias, distinct, Mr. Shaw gained the first prize with fine even blooms, those of John Bennett, Burgundy, Duke of Edinburgh, Flag of Truce, Victory, and Oracle being really beautiful. Mr. Griffiths of Hereford was second with blooms nearly equal to the first-prize stand, but smaller in size; his best examples were *Norfolk Hero*, *Donald Beaton*, *Vice-President*, *Lord Napier*, *Charles Wyatt*, *Monarch*, and *Rev. J. B. M. Camm*. For twenty-four Dahlia blooms, first, Mr. J. Sparke, Breadenheath; J. Bodenham, Esq. (gardener, Mr. Lawrence), second, with much the same varieties as those enumerated. Mr. Shaw and Messrs. Jones and Sons were the principal exhibitors of Gladioli, and staged some fine spikes. In the class for twelve trusses of stove and greenhouse flowers Mr. Pratt was first with fine fresh examples of red and white *Lapagerias*, *Stephanotis*, *Ixoras*, *Dipladenias*, *Ericas*, and others. Second, Messrs. Pritchard & Sons; equal second, Messrs. Jones and Sons; third, Sir C. Rouse, Broughton. Twelve bunches of hardy flowers, Messrs. R. W. Withers, Townsend, and Jones, were the prize-takers in the order named; the chief prizewinners in the classes for Phloxes being Messrs. Pritchard & Sons, Messrs. Oldroyd & Co., and Mr. R. Cooper. In the classes for Stocks, Carnations, Marigolds, and Pansies, Messrs. Shaw, Myers, Phillips, Cooper, Shuker, and Mrs. Hunter were the successful exhibitors. The bouquets were good and

numerous. For the bridal bouquet Messrs. Jones & Sons gained the first prize; Mr. H. Jones, Cotton Hill, second; and Mr. Cypher, third. For the ball bouquets the same exhibitors gained honours in the order stated.

FRUIT.—This was shown extensively and well, principally by local exhibitors. R. C. Naylor, Esq. (gardener, Mr. Hanagan), staged some excellent fruit in the collection of nine dishes, including good Muscat of Alexandria Grapes, Madresfield Court being well coloured and large in the berry; fine Grosse Mignonne Peaches, Pitmaston Orange Nectarines, Jargonelle Pears, White Heart Cherry, Brown Turkey Figs, Green Gage Plums, and Bloxholm Hall Melon. Mr. Pratt was second with a good collection, including fine Black Hamburgh and Foster's Seedling Grapes. Mr. Warrender was third. For the collection of Grapes an extra prize was given by Lord Hill. Mr. Pratt obtained the first prize with good well-finished bunches of Black Damascus, Black Hamburghs, and Madresfield Court; G. D. Lees, Esq., second with Black Hamburghs, Alicante, and Lady Downe's; Lord Forester, Willey Hall (Mr. Stevens), also staged good examples. Seven collections were staged in the class for white Grapes—first, Viscount Boyne (Mr. W. Boddy), with fine large bunches of Muscat of Alexandria; second, Sir C. Rouse, Broughton (Mr. Bean), with fine bunches of Buckland Sweetwater. Mr. Pratt was first with a Pine Apple with a large fruit of Charlotte Rothschild. Dish of Peaches, Sir F. Smythe, Bart. (Mr. J. Edwards), was first with large fruit of Albatross; Mr. Shaw second with fine coloured Grosse Mignonne; third, C. G. Wingfield, Esq. (Mr. J. Lambert). In the class for Nectarines Mr. Bean, Mr. Hanagan, and Mr. Warrender all showed Pitmaston Orange, the two first named staging very fine fruit. For a dish of green or yellow Plums, Mr. Hazledine, Lord Berwick, and J. Watson, Esq. (gardener, Mr. H. Purser), obtained the prizes. In the corresponding class for red or purple W. H. Harrison, Esq., and Mr. Williams, Ludlow, took the prizes. In the class for a green-fleshed Melon, first Lord Berwick, second Mr. Owen, third R. C. Naylor. For a scarlet-fleshed Melon, first, Mr. Owen, with Hero of Bath; second, R. W. O. Withers, Esq.; third, Miss Drownwood.

VEGETABLES.—These were shown in great quantities, and from what we have seen at various shows this undoubtedly proved the best display of the year. The vegetables occupied three parts of the side staging round a tent 250 feet long, the stage being about 3 feet 6 inches wide. In the class for a collection of vegetables, twelve varieties, there were fifteen entries. C. C. Coates, Esq., obtained the premier award, staging Snowball Turnip, Dell's Beet, Schoolmaster Potatoes, Fulmer's Forcing Bean, Telephone Peas, Clarke's Red Celery, Veitch's Autumn Giant Cauliflowers, Hathaway's Excelsior Tomatoes, Cucumbers, Vegetable Marrows, and Globe Artichokes. Second, R. C. Naylor, Esq., with the neatest and most suitable collection for table purposes in the Show; the best dishes being a fine brace of Telegraph Cucumbers, Marvel Peas, Early London Cauliflowers, Schoolmaster Potatoes, and good Intermediate Carrots. Third, Mr. Lambert. The Cucumbers and Celery were good in this collection. Good collections were also staged by Mr. Pratt, Lady L. H. Coates (J. McLean), and G. D. Lees, Esq. In the class for six dishes of Potatoes eighteen competitors appeared. Mr. Edwards gained the first prize with good examples of Beauty of Hebron, Porter's Excelsior, International, Grampion, and Woodstock Kidney. Second, Rev. R. D. Corbett with Webb's Surprise, Fox's Seedling, the other varieties the same as mentioned above. Third, Mr. Lambert with similar varieties. In the class for three dishes equally as many were staged; Mr. J. Williams, Rev. R. D. Corbett, and Mr. A. Myers taking the prizes. The prizes for Tomatoes were taken by Lord Berwick, Mr. Pratt, and Mr. J. Watson. The remaining vegetable prizes were well contested, and the principal prizetakers being the same as given in the other vegetable classes.

COTTAGERS' CLASSES.—This Society sets a good example to many others in providing in their schedule thirty-seven classes entirely devoted to cottagers, and a large tent 200 feet long was devoted to them. The plants exhibited only require a passing note, but the inducement of prizes encourages the masses to grow window plants, and this is worthy of acknowledgment. The hardy cut flowers were numerous and very satisfactory. Vegetables and small fruits occupied the greater portion of the tent, the former being most numerous, especially Potatoes, some thirty competitors staging single dishes. Carrots, Parsnips, and Onions were really good, and in many cases much superior to some shown in the open and amateurs' classes.

The Committee deserve the warmest congratulations for the manner in which the Show was conducted; and the improved system adopted over that of last year in placing the prize cards upon the exhibits. The success of the Society in a large measure is due to the indefatigable exertions of the two Honorary Secretaries, Messrs. Agnitt and Naunton.

EXHIBITING ORCHIDS.

I, FOR one, quite agree with your correspondent "N." (page 134), that the way Orchids are now exhibited requires serious consideration. If the system of bedding-out dwarf-growing Orchids at exhibitions is to be encouraged, by all means let there be a class or classes provided in the schedule for such; and if single specimens be encouraged let the judges be empowered to use all legitimate means to detect made-up specimens; and where an attempt at fraud is detected, let the exhibit be at once

disqualified. For a tray or pan containing from twelve to twenty distinct plants to be staged and judged as a single specimen against a *bonâ fide* specimen plant is manifestly unfair, no matter how creditable they may be as a whole or individually. The massing of dwarf-growing Orchids is undoubtedly a step in the right direction towards producing a glorious display of such plants, and is worth the attention of those whose business it is to draw up the schedule. It is said there is no Act of Parliament but a coach and four may be driven through it, and it appears to me that there are rules of horticultural exhibitions through which a costermonger's flower tray may be carried.—J. U. S.

SUNDERLAND FLOWER SHOW.

THE above Show was held on Wednesday, August 10th, in the Albert Hall, Toward Road, in close proximity to the principal park in Sunderland. As it was not possible to hold all the Exhibition in the Albert Hall, a capacious marquee was extemporised adjoining to the building, where most of the gardeners' and amateurs' produce were placed. The Committee were well organised, punctual to every minute detail, even to exactness; the Secretary's office being conspicuously situated in the hall, where access was easy. Another feature not unworthy of mentioning perhaps is that placards were freely posted over the Exhibition telling the names of the members of the Executive Committee, so that exhibitors knew whom to apply to at once. In the centre of the hall was placed a stage running lengthways, on which the principal plants were exhibited, the boards of which were mostly covered with machine-cut grass; this amongst the pots had a neat and pleasant appearance.

In the open class for six plants Mr. John Thompson, nurseryman, Newcastle, was deservedly first with very fresh plants of *Clerodendron Balfourianum*, a large *Rondeletia speciosa* major, *Erica Wilsoni* *superba*, and an average *Dipladenia amabilis*. R. Gaynor, Esq., The Cedars, Sunderland (Mr. Graham), was second with two good *Allamandas*, a good large *Stephanotis*, and a *Bougainvillea*. Mr. Gardner, Dunston, was third.

The Society offered £3 for six foliage plants. There were five competitors. Mr. Graham was deservedly first with, amongst others, a fine *Encephalartos villosus* and a handsome *Croton Andreanus* 7 feet high. Theo. Fry, Esq., Darlington (Mr. Noble), was second with a good *Cycas revoluta* and a *Croton Johannis* superbly coloured. H. Cravan, Esq., Sunderland (Mr. Appleby), was third. For six exotic Ferns Mr. Noble was first with very good specimens of *Davallia Mooreana*, *Gleichenias speluncae* and *rupestris*, and *Adiantums*. He was also first in the gentlemen's gardeners' class for six, and obtained premier honours with British Ferns. In the gentlemen's gardeners' class for six plants Mr. Henry Watson was first, Mr. Noble was second, both with good specimens. The foliage plants in this class were also good. Zonal *Pelargoniums* were in all classes excellent, very fresh, well flowered, and not too formally trained, the entries filling one side of the marquee. Mr. E. Laidlaw was first with a good collection.

Table plants, cut flowers, fruit, and epergnes were arranged round the hall on side stages. For twelve bunches of cut flowers Mrs. Pease (Mr. McIntyre), Woodside, Darlington, was first, a special prize of £2 10s. being offered. Bouquets and epergnes were exceptionally fine, Sunderland exhibitors having already gained a well-earned success. Mrs. Crament, Sunderland, was first for both bridal and hand bouquets; Mr. Watson, Laurence Street, Sunderland, being second. There were nine epergnes, all of which were above the average. John Henderson, Esq. (Mr. Thos. Rutherford), Leazes House, Durham, was first, the second and third being both creditable. In the open class the fruit was very inferior. The first prizes for black and white Grapes were gained by H. Stephenson, Esq., M.P., Westoe (Mr. Henry Smailes), the Grapes being well finished. Some average dishes of Peaches were exhibited, but all the fruit was shown unnamed. This great defect also occurred in many other classes, and the Committee would do well another year to strictly enjoin the naming of all the exhibits.

Florists' flowers were not numerous; Mr. Walker, Low Fell, and Mr. Harkness, Allendale, winning the principal prizes for Dahlias with flowers that were rather coarse, although of good size. Mr. Spoors of Swalwell had some fine *Gladioli*; and Mr. Battersby, Hogg Hill, staged some excellent *Phloxes*.

A great portion of the centre of this tent was devoted to *Fuchsias*, which were in fine condition. The vegetables were excellent. Mr. Lambert of Whickham exhibited two Cucumbers, not named, nearly 3 feet long. Messrs. Fell & Co., and Messrs. Joseph Robson & Son of Hexham, contributed excellent stands of *Coniferae*, alpine and bedding-out plants, which were much admired. We hope by another year, with the exertions of the Committee, and the business tact and courtesy of the Secretary and Treasurer, Messrs. John P. Chapman and J. Blacklock, that still better results will follow financially and horticulturally.—B. COWAN.

THE HOLLYHOCK DISEASE.—I send you a sequel to my note on Hollyhocks of several weeks back. The fungus proved too much for me, attacking not only the leaves but the stems. Then I cut every one of them an inch or two below the surface of

the soil, and made only the clean eyes and offsets into cuttings. In the frame the fungus was not long in appearing, and pinching off leaves and throwing away badly infected cuttings is again the order of the day. But worst and strangest of all, the growths sent up by the old plants are also more or less diseased, and where could it come from? They will be cut off again in a few days, and the clean growths propagated.—R. P. BROTHERSTON.

THE SHANKING OF GRAPES.

ANYTHING from Mr. Harrison Weir's pen or pencil is always interesting and generally reliable. There are doubtless thousands like myself who eagerly catch at anything from the friend we seem to meet and fraternise with every day of our lives. We know that what he undertakes to do he makes up his mind to do well, be it to sketch a bird's nest or grow a bunch of Grapes. There are certain cases, however, in which this very confidence is a source of danger, from the fact that many might be inclined to take without question any new plausible theory from such a source and throw to the winds that which is an indisputable practical fact. Probably less than twenty years ago shanking was by the majority of gardeners considered to be a disease, and as such there was scarcely any hope of entirely preventing it; but we have advanced since then, and can now produce shanking at will. Happily, also, we can to a considerable extent check it when it does unfortunately appear. Mr. Harrison Weir says "a Vine may be in first-rate condition, the roots, the wood, and foliage right, and yet the fruit will shank." This is quite true as far as appearances go, and the Vine may be even luxuriant; but we know that the best of us can be easily misled by appearances, especially in the case of Vines with which we are not personally acquainted. Some which look weak and puny will produce a marvellous crop of fruit year after year; others which are strong and luxuriant are liable to have some failing peculiar to them, the effects of which are difficult to hide even in the hands of the most experienced, while even the much-coveted moderate canes with ripe plump buds are not all we could wish. The explanation is, that though there may have been everything necessary to produce wood growth, there has been a deficiency of something essential to the perfect production of fruit. The deficiency may be in the soil, but it is not always there. Sometimes a grower who has been eminently successful in one place will move to another, and find great difficulty in satisfying himself with his productions.

The fact is gardeners know too little about the constituents of soils. Those of us who have a good knowledge of fruit culture succeed admirably so long as we have an unlimited supply of new loam and take ordinary precautions, even in districts where fruit does not succeed well naturally; but to cart a large quantity of the top spit of a pasture about every other year to add to a Vine border, as many of the foremost Grape-growers do, is very expensive, and in these hard times for landed proprietors, which show no signs of diminishing, cannot long be allowed; neither will any expenses be likely to be allowed in the long run which do not return an ample market value. I do not mean that the crop produced must necessarily be sent to market, but that it must be produced for the same amount it would fetch there; and that although it is very desirable to please the eye in prosperous times, it may become under altered circumstances more important to study the exchequer. I am afraid that many gentlemen look on their gardens as very expensive luxuries. That they are luxuries as far as the ornamental part is concerned there is no doubt, and employers are justified in curtailing expenses in that quarter if they are beyond their means; but the productive part of a well-managed garden, even in a bad season like the last, more than pays for its expenditure, and that employers would soon find out were they to buy all they require for a couple of years instead of growing it. Unfortunately, the ornamental and the useful are so mixed for the sake of economising space and labour that it is not possible to show the exact expenditure of either department.

There are many places where good culture alone with the natural soil would produce magnificent Grapes, and I believe there is no place in this country where an unlimited quantity of soil is added to good culture that good Grapes could not be produced after a few years. Now if we examine the conditions under which Vines flourish naturally, we find that it takes very little indeed in bulk to satisfy them; and does not this show, that although carting loam by hundreds of loads is very successful, it is nevertheless a cumbrous method, and that if we knew the particular ingredient or ingredients lacking in the soil already surrounding the roots, we could probably supply it in one load instead of in fifty? To illustrate what I mean, and show how easily one may be misled by the surroundings, I may mention a case of my own. I am situated almost between two hills of lime-

stone, one of which is only half a mile away and the other about three miles, both of which produce lime of good quality. If any one had told me that the soil here was likely to be deficient in lime I certainly should not have believed him, but nevertheless I have been here long enough to prove that it is exceedingly deficient in that essential, and am surprised at the results of applying lime to it. A similar thing may happen in other localities with respect to other ingredients, and as it was ten years before the thought dawned on me of what the deficiency was, it may be so in other cases unless chemistry is invited to our aid.

I am much obliged to Mr. Harrison Weir for giving me a peg to hang these rambling notes on, and will endeavour once more to attend to his subject. That writer says, "The best remedy for shanking in my opinion is sulphur on the pipes." If shanking were caused by fungus this would unquestionably be an effectual remedy; but unfortunately for the fungus theory, as well as the proposed remedy, there is the fact that till within the last few years almost every grower was in the habit of placing sulphur on the pipes for another purpose, and it did not prevent the shanking. Shanking is always caused by a vitiated or a deficient supply; it may be owing to the want of sufficient foliage or of healthy roots; it may be from the lack of some essential ingredient in the soil, or from insufficient water. Generally speaking, if the foliage is good, a little stimulant administered to the roots with warm water will temporarily check the evil. The writer says further on to the effect that the plan of cutting off the shanked part would be of no avail if the damage came from the root. I answer, Neither is it, except for appearance.—WM. TAYLOR.

THE shanking described by your esteemed correspondent, Mr. Harrison Weir, is not the shanking with which experienced Grape-growers are so familiar. Shanking is a disease incidental to the critical stoning period of Grapes, just as shrivelling and falling off is incidental to the stoning or seeding period of Peaches, Plums, Cherries, and Apples, &c. In the Vine shanking always happens about the period the seeds begin hardening. The berries, instead of changing to the sugary state, lose their freshness and become mere bags of water of a most disagreeably sour taste, and shrivel and drop in the end, and this happens generally before the footstalks perish. If a berry be pulled off and squeezed it will drop nothing but clear water, and leave a skin behind. What is the immediate cause of the disease is yet a mystery, but one thing is certain, and that is that excessive cropping will produce it. If the shanked berries are allowed to hang the footstalks will turn black and shrivel, but that has little to do with the disease.—J. S. W.

TAUNTON DEANE HORTICULTURAL SOCIETY.

I HAVE again had the pleasure of officiating at the Exhibition of this very flourishing Society (and where all the arrangements are so admirably carried out it is a pleasure), and again have been astonished at the zeal with which these west country shows are carried out and the interest taken by all parties in them. I cannot but contrast them with those of the south-eastern district. The value of the prizes, the amount of the exhibits, and the attendance of visitors are all in such striking contrast, that to compare them would be indeed Olympus to a molehill; and it must be recollected that it is not merely in the county town, but at Weston, Bridgewater, Sherborne, Barnstaple, and all towns of any size that these autumn shows take place. Railway stations and hoardings are covered with huge posters, in which the Societies seem to vie with one another as to which shall offer the best prizes and present the greatest attractions. Exhibitors leave, but others take their place; the cottagers exhibit better every year, and some of their exhibits show that taste is not confined to the middle and upper classes.

In noticing the stove and greenhouse plants, which are always so good here, some idea of their merits may be gained from the fact that Mr. Cypher of Cheltenham only came in second, the place of honour being allotted to Mr. Fawkes of Exeter, whose gardener Mr. Cole (one of the Manchester Coles) shows that wherever they migrate they carry with them their almost unrivalled skill as plantmen. It were useless to give the names of the plants exhibited. We all know at this season of the year what they must be; and when Mr. Cypher, Mr. Cole, and Mr. Tudgey were the exhibitors we may be quite sure that the very best were shown. There was a falling-off in the foliage plants and Ferns, but in the other departments there was a decided improvement. The cottagers' productions were grand, and they might very easily have competed with the gentlemen's gardeners. It was not simply that the vegetables and flowers were good, but the taste displayed in bouquets was very great amongst them; indeed I have rarely seen more taste than in the bouquets of wild flowers, which, moreover, were so numerous that the Judges felt compelled to award double the number of prizes offered in the schedule. In this tent, too, were exhibited the table decorations and bouquets. In both of these Miss Cypher again took first, although it is evident the lessons

that she has been teaching the Taunton folk have not been thrown away, for Miss Virgo had an arrangement very much in her style and very meritorious. It is not merely that Miss Cypher displays her excellent taste in the selection and arrangement of her flowers, but that all the appointments of the table were chaste and elegant; the centre one was too high for the present taste, where everything must be as low as possible. But by-and-by there will be a return to this style, which would never have gone out of fashion if it had not been for the monstrosities that some people erected, carrying the arrangement to its absurd extreme, and completely hiding those at one side of the table from those on the other. The latest absurdity I have seen of the present extreme was the scattering of Geranium petals on the cloth!

Nothing can possibly be more painstaking than the manner in which all the details of the Show are carried out under the direction of their able and indefatigable Secretary Mr. Clement Smith, and there are few places where a flower show can be more heartily enjoyed than in the pleasant county town of Somerset.—D., Deal.

EARLY ROMAN HYACINTHS.

THE bulbs for producing the earliest flowers at the end of October and beginning of November have been potted, and successional batches will require potting according to demands. The potting of the last batch should not be delayed too long. It is a frequent practice to defer potting in order to maintain a supply of these delicious white flowers over the longest possible period. This is a mistake. The bulbs should not be kept too long out of the soil; if kept until a glutinous substance oozes out of them they seldom do much good afterwards, and those are frequently blamed from whom the bulbs have been purchased. The early nature of the Roman Hyacinth has taught us that potting should be done in good time, and retarding done when the bulbs are removed from the ashes or the material used for covering them after potting. It is important to remove them from the covering before much growth is made, at least as soon as the bulbs are well rooted, gradually exposing them to the light. Those of the latest supply should occupy a northern position. After becoming thoroughly green abundance of air and water should be given them liberally.—W. B.

THORNTON HEATH HORTICULTURAL SOCIETY.

MUCH finer weather favoured the fourth annual Exhibition of this Society than that which rendered the Show last year comparatively unsatisfactory. The exhibits, too, were fairly numerous, one large marquee being filled with plants, cut flowers, fruit, and vegetables, which were generally marked by a freshness that is rarely exceeded at local shows. The schedule has undergone a careful and judicious revision, the money value of the prizes in many of the chief classes having been increased and other improvements effected that rendered it much better adapted to the requirements of the neighbourhood. Although the exhibitors came forward freely there was not any very close competition except perhaps in the classes for a group of plants and that for vegetables, in which the prizes were fairly contested. The vegetables were particularly well shown, not only by the amateurs and gardeners, but by the cottagers also. Cut flowers were bright and of good quality, plants numerous, but the fruit was poorly represented.

The principal class was that for a group of plants arranged for effect in the shape of a half circle, the space occupied not to exceed 10 feet by 7 feet, and in this there were seven competitors. These groups formed an important part of the display, for they occupied nearly the whole of the centre of the marquee, forming a line from end to end. The premier prize was gained by J. C. Lanyon, Esq., Birdhurst, Croydon (gardener, Mr. G. Fewell), who contributed a tasteful arrangement of Lilliums, Tuberosa Begonias, Crotons, and Ferns. Mrs. Howes, Waldron, Croydon (Mr. A. C. Roffley), and D. Cornish, Esq., Dagnall House, Selhurst (Mr. Elsey), followed with pretty groups. Stove and greenhouse plants were not very extensively shown. In the class for six specimens in flower the chief collection came from Canon Bridges, Beddington (Mr. Penfold), who secured the first prize with neat specimens of Bougainvillea glabra, well flowered; Vinca alba, V. rosea, and Rondeletia speciosa major. The corresponding class for six plants remarkable for the beauty of their foliage brought three fine collections. Mr. Fewell took the first prize with handsome examples of Casuarina sumatrana, 5 to 6 feet high and in excellent health; Stevensonia grandifolia, very fine; Croton variegatus, good colour; Theophrasta imperialis, vigorous; and Latania borbonica. Mr. Penfold was awarded an equal first prize for a collection, including admirable specimens of Areca lutescens, Croton interruptus, and Davidsonia pruriens, the latter being in splendid condition. J. Donner, Esq., Wood Hall, South Dulwich (Mr. Bristow), secured the third prize with neat plants. Hardy Ferns were well shown by Messrs. Penfold, Fewell, and Roffley, who gained the prizes in that order. Exotic Ferns were also noteworthy, a Dicksonia antarctica and Adiantum cardiochlaena in Mr. Fewell's premier collection of six being equally fine. Mr. Penfold, who was second, staged a good specimen of Neottopteris australasica among other species, Mr. J. Bristow taking the third position. Fuchsias, Pelargo-

niums, Gloxinias, &c., were fairly represented, but do not require special enumeration. The most successful exhibitors in these classes were Mr. Elsey, Mr. Fewell, F. Wilkins, Esq. (Mr. Wood), and W. T. Stuart, Esq. (Mr. Rice).

Among the cut flowers Dahlias were the most numerous and the best in quality, but Roses and Asters were also shown in fair condition. For twelve Dahlia blooms of distinct varieties Mr. L. Hakeman, 9, Cleveland Villas, Bensham Manor Road, Thornton Heath, easily obtained the first prize with an excellent collection of symmetrical finely coloured and well selected blooms. The most notable varieties were Yellow Boy, very fine; Grand Sultan, John Lamont, and Oracle. The Rev. J. Watson, the Vicarage, Upper Norwood (Mr. G. K. Wright), was a good second, and W. H. Collins, Esq. (Mr. W. Crane), Cyprus Lodge, followed with small but neat blooms. There were five entries in this class. In another class for six Dahlias Mr. Hakeman was again an admirable first, his blooms being of high quality. Messrs. Wright and Elsey followed with bright specimens. In the amateurs' class for six Dahlias Edward Mawley, Esq., Lucknow House, Addiscombe, staged the best collection; the second prize going to Mr. W. Plowman, Beddington Lane, near Mitcham. Roses were not first-rate, the two principal collections being those from Mr. J. Leete, South Norwood, and Mr. Edward Mawley. Mr. Penfold exhibited a good collection of Asters. The special prize for table decorations was obtained by Messrs. Bishop, West Croydon, with a simple, neat, and yet admirably tasteful arrangement in which Rhodanthes predominated, most pleasingly intermingled with Grasses, Mignonette, Ferns, and small Campanulas. Although of a very unpretentious character, this stand would have graced an exhibition of much greater importance.

Fruit was not very plentiful nor of extraordinary quality, but clean fairly well-ripened samples were shown by Mr. T. Welstead, Croydon, who gained the chief prizes in all the classes. Vegetables were uncommonly abundant, and in fine condition generally. The most successful exhibitors were F. Minchiner, Esq., 3, Shirley Villas, South Norwood; S. Atterbury, Esq., Thornton Heath; and Messrs. Fisher, Crane, Fewell, and Elsey. Potatoes were grandly shown by W. Gooch, Esq., 6, Enmore Park Villas, South Norwood; Mr. G. Woodham, North Dulwich; and Mr. Rice. Numerous miscellaneous groups not for competition were sent by several nurserymen and others, the most noteworthy being the handsome collections from Mr. B. S. Williams, Upper Holloway, and Messrs. Laing & Co., Forest Hill. Special prizes were offered by Messrs. Wm. Paul and Sons, Waltham Cross, Herts; Messrs. John Laing & Co., Forest Hill; Messrs. Hooper & Co., Covent Garden, London; Messrs. James Carter and Co., High Holborn; Messrs. Daniels Brothers, Norwich; Mr. B. S. Williams, and Messrs. Sutton & Sons, the majority being contested by several exhibitors.

All the arrangements were very satisfactory, and were highly creditable to the energetic and enthusiastic Secretary, Mr. L. Hakeman, who has laboured hard during the past year to render the Exhibition a success and to improve the condition of the Society. The Show was held as in previous years by permission of K. T. Oelrichs, Esq., in the grounds attached to Elm House. During the afternoon the prizes were distributed by one of the Vice-Presidents—W. Grantham, Esq., Q.C., M.P.

HOW ARE YOU OFF FOR WASPS?

A WITTY friend of mine wrote to me this week, and asked, "How are you off for wasps?" I replied, "I shall be very happy to spare you a million if you wish." Strange to say that this year wasps are the gardener's especial trouble (he always has one on hand, poor man!) Sometimes grubs, other years slugs or green fly, or too little rain or too much. The gardener has always a difficulty to face; well for him if he has not two, as the man had who said his chimney always smoked and his wife always scolded. I pitied that man. Well, I have said that it is strange that this of all years wasps are so numerous, for last year there was none, or, to use better English, there were not any. It was also so very wet that I thought of nests there would not be any, and that wasps would be exterminated. But it is not so; every few yards in the hedgebanks is a wasps' nest. Each small garden has one to boast of, and larger have more. They are worse than birds however numerous, for net your Currants, Gooseberries, Raspberries, Strawberries, and Cherries, and Mr. Blackbird and Mrs. Thrush are done, and sit on an Apple bough evidently thinking—"This is too bad. Guns were bad enough, but then a body had a chance, and we have good eyes and good wings; but these nets are disgraceful; we can see the fruit and can't get at it. Too bad, too bad; the world grows worse and worse!" The wasps are everywhere, and no sooner does one kind of fruit ripen or partly ripen than they begin their attack. Cherries first, then Gooseberries, now Peaches, Plums, Pears, and even Apples.

I have taxed my ingenuity to destroy them. Wide-mouthed bottles with beer and treacle in them are good, but they fill so rapidly that soon the wasps fly out triumphantly, sipping the nectar in safety standing on the corpses of their brethren. I have a great number of these standing on the ground and hanging in

the trees, but still the wretches come in thicker swarms; each bottle may kill a corporal's guard, but what is that out of a whole army? Then as to the nests. In olden days we blew them up with gunpowder late at night, and there was high excitement among the boys in the village lane—they looking on. Then the pause before the explosion, then the wasps around their heads after, then the delightful feeling of experiencing or being on the verge of danger. We don't do this now; we pour gas tar into the holes, about a pint will do, and the wasps that are in can't get out, and those that are out can't get in! But at no time are all the owners of a nest at home. At night they sleep, if they sleep at all during the glorious carnival of the fruit season, in Apples and other fruits hollowed out by their industry. In spite of treacle traps and gas tar, which we have to give sometimes more than once, as the inside gentry make another hole and so, some of them at least make a way of escape.

But now for the best plan I know, which traps all those wasps that are flying about. Take two handlights; place one on the ground, but raised about an inch from the ground by a piece of

Fig. 42.—Wasp Trap.

wood at each of its four corners. Break two small holes in the top of this handlight, put a few pieces of Apple on the ground under, place another light of exactly the same size on the top of this, laying moss all round the edge where the two meet. The wasps, attracted by the Apples, enter. When they have eaten they naturally fly upwards, pass through the holes into the upper glass, where they in a short time die from starvation, falling among the moss. They never think of crawling down through the holes. Thus they are trapped. I have just seen as many wasps caught in this way as would come from two or three nests. The only thing to do when once the trap is made is to continue to put in fresh pieces of Apple or Pear or any other fruit. I enclose a rough sketch for the better understanding of this plan.—WILTSHIRE RECTOR.

[This is one of the oldest and one of the best modes of trapping wasps that we are acquainted with.—EDS.]

WINTER ONIONS AND SPRING LETTUCES.

ONIONS.

SEED of this useful esculent should be sown this month for a spring supply of bulbs, and some time between the 15th and 30th day of the month is a good time for sowing it. If sown before the former date there is a risk of the young plants running to seed, and if after the latter date the seed must be sown on well-prepared pulverised soil, and on land that is well drained. An open position is at all times necessary, away from the shade of trees. A good dressing of old manure should be dug into the ground a fortnight if possible before sowing, leaving the surface rough and open to the action of the air, then after a shower or sprinkling with water the clods will fall to pieces easily, and the ground be in good condition for receiving the seed, which should be sown in drills a foot apart, covered over and trodden firmly.

The White Lisbon variety I have found to be very hardy, having endured the last two winters well; it has also a very mild flavour. When the young plants can be seen in the rows a Dutch hoe should be run through them to destroy small weeds and promote healthy root-action. The rows should also be hand-weeded; and in October, especially if dry, the hoe should be run through again, twice if possible; they will then take care of themselves till the spring.

In March, when vacant ground is more plentiful than in August, another bed is prepared, using plenty of manure. Drills are made a foot apart, and enough young Onions drawn from the seed bed to plant 6 inches apart in the rows, not inserting them too deeply. These come in for kitchen use in early summer after the old stock of store Onions are over, and before the young Onions sown in March are ready. The young Onions in the seed bed from which these are drawn are used in a small state for saladings. The rows can be cleared as wanted, the ground hoed, and Brussels Sprouts or Cauliflower planted in it without being dug. If the ground is firm and solid so much the better, as, if too hard for making the holes with a wooden dibber, an iron crowbar can be used.

It is not a bad plan to sow half the Onion crop in August, and if large Onions for use in summer are in much request, the Tripoli kinds and Giant Rocca may be sown as well as the White Lisbon. The last-named is grown largely for bunching as young Onions in March, April, and May, to send to Covent Garden and other markets.

SPRING LETTUCE.

The old Bath or Brown Cos when well blanched in April and May is admitted by most gardeners to be one of the hardiest and best eating Lettuces grown, and such I have found it. As last winter was a pretty good test respecting their hardihood, two other varieties were sown at the same time (the 20th of August) with it—the Early Paris Market Cabbage Lettuce and Hick's Hardy White. These two proved to be equally as hardy, the Early Paris Market coming into use first, Hick's Hardy White second, and the Bath Cos next, keeping up a supply till the spring-sown Lettuce came in. The Paris Market hearts a little quicker than that useful variety All the Year Round; and as early Lettuces in spring are much sought after, these notes may not be out of place, as there is yet time to sow the seed on a warm border. The Paris Market, too, if sown in February at the foot of a wall, in a warm position, and thinned to 5 or 6 inches apart, is fit for use quicker than any variety I know of. At all times as opportunity occurs the hoe should be kept at work between them, not so much for the sake of destroying weeds as to promote free growth, thus causing the crops to come into use earlier than would be the case if the ground was not touched.—A. HARDING.

CUTTING VINES IN SUMMER.

OF all the plants in our gardens few or none will bear cutting or pinching while in a growing state better than the Grape Vine. If a leading rod or a side shoot is stopped or taken off at any part, the bud below this sends forth a fresh shoot in a remarkably short time, and it only takes a few weeks for this to attain the full dimensions of the original growth; and further, a green Vine stopped all over on one day soon becomes a flourishing mass of young shoots again without showing the slightest injury. Taking these facts into consideration, it is surprising that many should regard cutting the ripe wood of Vines as being so ruinous to the Vine's constitution. After the wood begins to turn brown it is very seldom touched with the knife, and at pruning time the utmost care is taken to prevent the smallest wound bleeding. Whether this may be necessary or not I will not argue at the present time, but I wish to state that, so long as the leaves are on the Vines, any part of the wood may be cut without any sap escaping or injury being done.

In these days of economy, and as many Vines are now grown, the summer growths are so interlaced, and the leaves so crowded over the shoots, that the wood has no fair chance of ripening until the best weather for accomplishing this is over, and all the fullest and best buds are formed at the extreme or wrong end of the shoot, as it is those buds nearest the main stem which produce the fruit the following year. To swell up and ripen these buds thoroughly may be regarded as one of the arts of Grape-growing, and to secure this very desirable end the present time should be taken advantage of to cut in all Vine shoots made this season. Shoots from which the fruit may have been cut may be shortened back to 8 or 10 inches from the main stem, and those bearing fruit to one eye beyond the bunch. All wood intended to ripen may be treated in this way without incurring any danger of starting a second growth, and the advantage of the operation will be distinctly visible next season by the free way in which the Vines start into growth, and the profusion of bunches as well as the general improvement of the Vines.—A KITCHEN GARDENER.

ROSE PROGRESS.—I was recently looking over a full catalogue of Roses of 1865-6, and think your readers may be interested to know that out of 270 H.P.'s quoted there only thirty-five are at

present in cultivation by the trade, and that out of this thirty-five only some twenty-five would rank as exhibition flowers. This shows 235 discarded in fourteen years—i.e., replaced by superior blooms. As really good, new, and distinct Roses are scarce this seems to point to a rapid progress, and the difficulty with growers now is to keep down the number of varieties, as old favourites are hard to discard.—GEORGE BUNYARD, *Maidstone*.

P.S.—The Teas of that day are still our best varieties.

DISA GRANDIFLORA.

It appears from the excellent notes (page 109) of my friend Mr. Tymons that this lovely Orchid is again coming to the front. I say again, for I can recollect when nearly twenty years ago there was a tremendous furore about it. At the grand opening day of the Royal Horticultural Society's Gardens Donald Beaton wrote thus, and whoever wrote such reports of flower shows as he did?—"At the extreme east stood two large pans of *Disa grandiflora*, from the top of Table Mountain behind Cape Town, from Mr. Leach, the greatest effort of prize gardening of all that was at this Show. No one in Britain has yet succeeded in growing this plant to perfection except Mr. Leach himself, and he says it is as easy as any other plant when the right treatment is given—say a mountain plant from a bog as hardy as any Cape Geranium. I have patronised this plant from the first to test the skill and patience of our craft, and now I am happy to be able to record that all the difficulties have been entirely got rid of." In a number of the Journal later on, in recording the first grand Rose show held at the Horticultural Gardens he said, "C. Leach, Esq., Heys Road, Clapham Park, sent three large pan-pots full of his glorious *Disa grandiflora*, the very finest terrestrial Orchid in the world, and there is none in the air to compare with it; moreover, it was in full perfection as it was never seen before in Europe."

It was a month or so after that—desirous of obtaining a drawing of it for the "Floral Magazine," which I then edited—that I paid a visit to Mr. Leach, and described in the Journal my impressions of it "at home," and these were my words. The "Cottage Gardeners' Dictionary" in describing it had said it has hitherto baffled the skill of British cultivators. I said this can be no longer said. "Mr. Leach had been in the habit of receiving it from the Cape, and believing, as all the world did, that it required its season of rest, he allowed it to dry off in the winter, and as a necessary result lost it; but one autumn, noticing that a plant still retained its verdure, he determined to see whether keeping in a growing state would suit it. This was the very point to hit, for when the shoots of the present year die down—yea, before they do so, the bud is springing up alongside of it that is to form the new plant." Mr. Leach made no secret of his culture. He told it to all who were interested. He gave one of his largest plants to the Royal Horticultural Society. He presented twenty plants to the Gardeners' Benevolent Society, which were sold by auction for its benefit, and he gave plants to friends; yet for one reason or another persons did not succeed with it. I have generally when visiting collections of Orchids asked to see it, but it has usually been in very poor condition. I have known large quantities of it to be imported by some of our largest growers, but they have failed. I saw it a few years ago at Glasnevin in fine condition. It was admirably grown by Mr. Salt; and I also saw it very well grown at Chatsworth. For some years I grew it well, Mr. Leach having kindly given me a plant; but when I came out here twelve years ago it dwindled away and I lost it altogether. As I in no way altered my treatment of it I could not account for this, but a friend to whom I was speaking about it suggested it was probably owing to the chalky nature of the water. Two years ago I purchased a clump of it from the Colchester Bulb Company, and was disappointed, knowing its history, to find that it was a dry lump. However, it started, grew well, and this year I have had the satisfaction of seeing it once again in flower, the plant having thrown up two flowering stems with a couple of flowers on each. I have as far as possible watered it with rain water, and the last two years have not often left us without a supply of that. But I am more inclined to think that the character of the peat has something to say to its success. Mine was procured from Mr. Epps, and in that it has thriven well. The present year's shoots are beginning to show symptoms of decay, but I see at their base strong sturdy shoots ready, I hope, for next year's work. I have nothing but a cool greenhouse from which frost is excluded; in this I keep it through the winter. When spring advances I bring it near the door, the position in which I saw it at Chatsworth. I have a syringe lying close by it, and I syringe the plant every time I go into the greenhouse. I should add that I prefer a pan to a deep pot for

growing it in, and that the drainage must be very good. But Mr. Tymons has so clearly shown the best way of cultivating it that I have no intention of adding to his paper, but simply to give a little of the past history of *Disa grandiflora*, which may have escaped the recollection of those who are now interested in the plant.—D., Deal.

[We shall next week publish notes on raising *Disa grandiflora* from seed, by Mr. Tymons.—EDS.]

HERTFORDSHIRE COUNTY FLOWER SHOW.

PROBABLY the first horticultural Exhibition ever held in the town of St. Albans took place on Friday and Saturday last in the grounds adjoining Gorhambury Lodge, that site having been kindly placed at the disposal of the Committee by the President, the Earl of Verulam. The Show was projected by the Herts Bee-keepers' Association, and by the aid of the energetic Honorary Secretary, the Rev. H. R. Peel, the preliminaries were successfully carried out, and the two exhibitions were held in conjunction. A report in another page indicates the success of the bee-keepers' portion, and if the horticultural display was not quite so extensive or so generally satisfactory as might have been expected, it was certainly no fault of the management. Of the eighty classes enumerated in the schedule all were confined to county growers, but many of these admirably endeavoured to sustain their credit, and to some extent succeeded in their efforts. The plants, fruit, and flowers occupied one large marquee, and a portion of another was devoted to vegetables and the cottagers' productions, the arrangements being satisfactory with the exception that too heavy a canvas was employed for the marquees, which was the more noticeable as the early part of the day was very dull. A large proportion of the plants exhibited consisted of collections from nurserymen not for competition, and brightened the Show considerably.

The principal class was that for a group of plants to occupy a space of 100 square feet, and in this there were only two exhibitors. Mr. Aylott, Oaklands, St. Albans, was first with an elegant arrangement of Ferns, Colcuses, Achimenes, and Pelargoniums, the chief feature of the group being the baskets of *Panicum variegatum* and *Tradescantia zebrina* suspended over it. Mr. D. Springings, The Nurseries, St. Albans, followed with Crotons, Lilioms, Ferns, &c.—healthy plants, but not disposed in a particularly artistic style. For nine stove and greenhouse plants, W. B. Greenfield, Esq., Beechwood Park (Mr. J. Freeman), gained the first prize with the only collection, which comprised a fair *Cordyline indivisa* and a healthy *Aloeasia Jenningsii*. The best six stove and greenhouse plants was staged by E. R. Fenwick, Esq., High Firs, Harpenden (Mr. G. Underwood), and included *Acalypha marginata*, *Vinca alba*, and *Cassia corymbosa* in vigorous health, the last-named being well flowered and not so leggy as it is usually seen. Colonel Sim, Bushey (Mr. Willocks), was second with a fine example of *Dieffenbachia Bausei* and a potful of *Vallota purpurea*. In the class for twenty plants suitable for table decoration Mr. Willocks was placed first with neat specimens of Palms, Dracaenas, Crotons, and Aralias. Mr. Sibley and Mr. G. Underwood followed with similarly neat plants. The only other exhibits of plants that require notice are the Ferns, of which two collections were staged, containing eight each. Mr. G. Underwood was first, specimens of *Adiantum formosum* and *A. concinnum* being notable for their freshness. Mr. Freeman was awarded an equal first prize.

Fruit was fairly well shown, a few of the collections containing really excellent samples. In the class for eight dishes Mr. G. Sage, The Gardens, Ashridge Park, Great Berkhamstead, was awarded the premier prize for well-coloured Black Hamburg Grapes, very fine Royal George Peaches, excellent Elruge Nectarines, handsome Morello Cherries, and an enormous Melon, The Squire. C. Butler, Esq., Hertford (Mr. G. Aslett), was second with a moderately fine collection, including good Morello Cherries and a fair Gilbert's green-flesh Melon. For six dishes of distinct fruits, H. J. Toulmer, Esq., Childwickbury, St. Albans (Mr. C. Pollard), obtained premier honours with ripe Pine-apple Nectarines, Moorpark Apricots, and Black Hamburg Grapes. Sir Andrew Lusk, Colney Park (Mr. Sibley), followed with neat and fresh specimens; Mr. Wm. Gurning, Brockett Hall Gardens, Welwyn, taking the third position. Messrs. Sage and Aslett were successful exhibitors of Pine Apples, both fruits being of medium size but well ripened. Black Hamburg Grapes were shown by the Rev. H. R. Peel, Hemel Hempstead, and G. C. Lockhart, Esq., The Elms (Mr. F. Froud), in fair condition and secured the chief prizes. Mr. G. Norman, The Gardens, Hatfield House, Hatfield, was the only exhibitor in the class for any other black Grapes, and obtained the chief prize for Madresfield Court, well coloured and of good size both in bunch and berry. White Grapes were exhibited by Mr. G. Aslett in fair condition, and he obtained the first prize in that class. Melons, Figs, and Peaches were represented by moderately good fruits, the latter being the best in quality. Mr. Sage and Mr. Sibley were the principal prizetakers.

Vegetables were fresh and clean, Messrs. Aylott and Sibley taking the majority of the prizes. Cut flowers were few and do not require special comment. The cottagers' productions were numerous, the vegetables being particularly well grown. Several neat collections of wild flowers were also exhibited, the specimens being very accurately named.

The miscellaneous exhibits were very numerous, the most important

being from Messrs. Cutbush & Son, Highgate and Barnet; Messrs. W. Paul & Son, Waltham Cross; Mr. Francis of Hertford; Messrs. Paul and Son, Cheshunt; Mr. Watson; and Mr. Springings of St. Albans.

WENTWORTH CASTLE.

By the kindness of Thomas Wentworth, Esq., the members and friends of the Sheffield and Hallamshire Gardeners' Mutual Improvement Society were allowed to visit the gardens at Wentworth Castle on August 3rd. On arriving at Birdwell station we were conducted to the Birdwell Lodge gates, and there commenced a most pleasant and instructive walk. The drive is about three miles long from the lodge to the castle, and on entering the gates the visitor is at once struck with the magnificent specimens of Beech; at least for 700 or 800 yards there is a continuous avenue of Beech, many having stems from 4 to 5½ feet in diameter. Emerging from the avenue into an open space there was a fine lake to the right with an island of Rushes in the centre, and a little further to the left were two grand old Elms. After passing over a bridge with rustic fencing there was another lake with several islands. On passing through another gate we were in the woods again, with an avenue on each side consisting of old trees of Oak, Ash, &c.; to the right were good specimens of Larch, the trunks being over 3 feet in diameter, one clothed with Ivy was very beautiful. We next entered the open park, the drive being lined with trees, one side grand Elms, the other Oaks.

On arriving at the gardens we were met by Mr. James Batley, the gardener, who escorted us through the private grounds, kitchen garden, and houses, to the famous old castle, rebuilt in 1720, which is said to have been besieged by Oliver Cromwell. The walls round the old courtyard are being fast covered with Ivy, and the banks and a yard are laid down with grass, and in the centre is erected a statue of the third Earl of Strafford. From the top of the castle the visitors obtained a fine view of Penistone and the surrounding neighbourhood. Near the flower garden is a monument erected to the memory of the Right Hon. Lady Mary Wortley Montague. The conservatory was next visited. *Tacsonia Van Volxemi* was growing there luxuriantly, the roof being almost covered with it. Mr. Batley said that for the last five years the plant had rarely been out of flower. The remainder of the roof was covered with the graceful *Cobaea scandens*. There was a large walk down the centre and one on each side of the conservatory. In the centre bed was a grand specimen of the Norfolk Island Pine, the other beds being filled with good examples of Oranges, Palms, Tree Ferns, and similar plants.

In the kitchen garden were some bushes of Red Currants loaded with large fruit. Peas, Celery, Lettuce, and vegetables generally were doing remarkably well. The first house we came to there was a cool greenhouse filled with Pelargoniums, &c., then came the Pine stove. The Pines both for succession and fruiting were looking well. The side benches of this house were occupied with Ferns and Dracaenas for table decoration. In the vinery late Grapes were very good both in bunch and berry. A sun-dial made in 1732 out of a Yew tree was greatly admired. In an Orange house a good specimen of *Tacsonia princeps* was in flower. In another vinery Muscat of Alexandria Grapes were fine, the bunches being large. The adjoining house contained Black Hamburgs and Gros Colman; the bunches and berries of the former were better than I have seen for several years. The next house was planted with young Vines growing very freely; a Vine in a pot was carrying two bunches of Hamburgs weighing over 5 lbs. each. On leaving this house and passing through the kitchen garden to the outer door our visit to the gardens terminated, everyone being quite satisfied with what they had seen. Permission having been granted for the visitors to see the picture galleries, many availed themselves of the opportunity. The party returned to Sheffield in the evening well satisfied with their pleasant excursion.—ROBERT HALL.

DEATH OF MR. ABRAHAM STANSFIELD.—Mr. Abraham Stansfield, of Vale Cottage, Todmorden, senior partner of the firm of A. Stansfield & Son, nurserymen of Vale Gardens, better known as Stansfield's Gardens, died rather suddenly on Sunday morning last, but for the last two or three years deceased had been in a very feeble condition. Mr. Stansfield had all his life been a most useful man to the town of Todmorden, having taken an active part in every matter which was for the good of his fellow men, and he had also won the respect and esteem of the inhabitants. He was a prominent friend to the Todmorden Scientific Association, and at the time of his death was President of the Todmorden Botanical Society, which post he had occupied for a great number of years. He had at various times of his life been fully engaged in public and private offices, and was very widely known and

respected. He was seventy-seven years of age at the time of his decease.

READING HORTICULTURAL SOCIETY. AUTUMN SHOW.

THE second Exhibition of the year was held on Thursday last in the Abbey Ruins, Forbury, and proved a great success in every respect, the exhibits being numerous, the weather exceptionally fine, and the attendance of visitors large. Plants were represented by many admirable collections containing bright healthy specimens. Cut flowers were very abundant, and added considerably to the pleasing effect of the Show; while fruit and vegetables were staged in first-rate condition, especially the former. The exhibits were very tastefully arranged, and a charming *coup d'œil* was presented to the visitor on entering the marquee at the higher end, the sloping and terraced sides being well suited for displaying plants to the best advantage. The management was generally satisfactory, but an unaccountable delay occurred in judging the plants.

STOVE AND GREENHOUSE PLANTS.—These were not represented by many collections, but the plants staged were mostly vigorous clean specimens. In the principal class for nine plants there were only two exhibitors, Mrs. Marsden, The Wilderness, Reading (Mr. Lees) gaining the chief prize with well-flowered *Eucharis amazonica*, a handsome *Allamanda Hendersoni*, and a neat *Rondeletia speciosa*. Mr. Mould, nurseryman, Pewsey, followed with smaller plants, among which were *Erica Austiniana* and a well-trained and healthy *Gloriosa superba*. In the corresponding amateurs' class for four specimens Major Storer, Purley (Mr. Mortimer), occupied the premier position, a specimen of *Bougainvillea glabra* being noticeable for the profusion of its flowers. E. Eyre, Esq., Welford Park (Mr. C. Ross), was placed second, his best plants being *Vinca alba* and *Justicia carnea*, the latter in much better condition than it is usually seen. Mr. Mould was first for a single specimen in flower with *Allamanda nobilis* in superb condition, the foliage and growth luxuriant and the flowers abundant. R. Floyd, Esq., Reading (Mr. Armstrong), followed with a well-grown *Eucharis amazonica*. For a single specimen new or rare plant Mr. Ross was first with *Maranta Van den Hecke*, a fine variety with dark green elliptical leaves and a white centre. H. J. Simonds, Esq., Caversham (Mr. Bezant), was second with *Dioscorea illustrata*, most luxuriant. J. T. Hall, Esq., Early Court (Mr. Bridge), sent the only collection of six *Liliums*, and was awarded the first prize for well-flowered examples of *Lilium lancifolium*, *speciosum*, *roseum* and *rubrum*, and *L. tigrinum* fl. pl. Mr. Mortimer had by far the best six Zonal Pelargoniums, his specimens being compact, healthy, well-flowered, the trusses of good size and the colours bright. Premier, Colonel Holden, and Mrs. William Paul were especially noteworthy. Cockscombs were shown in fine form by T. Somers Cocks, Esq. (Mr. Bridgeman) and Lord O. Fitzgerald (Mr. Lockie), who gained the prizes in that order with dwarf plants bearing enormous richly coloured heads. Messrs. Lees and Mortimer carried off the prizes for *Achimenes* with fairly good specimens. Colonel Clayton, Maidenhead (Mr. Burgess), had the six best *Coleuses*, neat pyramidal specimens and well coloured. W. Fanning, Esq. (Mr. Ashby), sent the finest collection of Tricolor Pelargoniums, plants of moderate size but very rich in colour.

FINE-FOLIAGE PLANTS.—In the class for nine specimens Mr. C. Ross obtained the coveted position with healthy examples of *Croton Johannis*, *C. Weismanni*, both well coloured; *Alocasia macrorrhiza variegata*, very luxuriant; *Bonaparteia gracilis*, and *Alocasia metallica*. Mr. Mortimer was second with a fine *Latania borbonica*, and several *Alocasias* and *Crotons* in good condition. Mr. Lees was third, his best plant being *Alocasia metallica* with remarkably handsome foliage. In the corresponding amateurs' class for four specimens the Hon. R. Boyle, Purley (Mr. Hope), and Mr. Bezant carried off the prizes with similarly clean examples of *Crotons* and *Alocasias*. Ferns were represented by several handsome collections, the premier nine from Mr. Mortimer being remarkably luxuriant and healthy. They comprised *Adiantum concinnum latum*, very fine; *A. cardiochlena*, also good; *Leucostegia immersa*, fresh; *Gymnogramma chrysophylla* and *Davalha Mooreana* of moderate size, but never exhibited in better condition, the plant being a mass of fine young vigorous bright green fronds about 2 feet long and broad. Mr. W. Lees was a good second with a neat *Adiantum farleyense* and *Asplenium bulbiferum*. Mr. Hope was first with four plants, *Adiantum formosum* and *Dicksonia antarctica* being notable in the collection. Mr. Bezant followed with smaller plants. *Selaginellas* were as usual well shown by Mr. Mortimer, who gained the chief award for neat conical specimens 2 to 3 feet high, *S. cæsia*, *S. Poulteri* and *S. apus* being the best; Mr. Hope was second also with neat examples.

GROUPS.—These were numerous, and contained plenty of colour judiciously softened by fine-foliage plants. Mr. Lees was the most successful exhibitor, his group principally consisting of *Liliums*, *Fuchsias*, and Ferns. Mr. Phippen, nurseryman, Reading, was placed second with an effective arrangement, and Mr. Burbridge third. An extra prize was awarded to F. J. Bland, Esq. (Mr. Powell.)

CUT FLOWERS.—Much of the brightness of the Exhibition was due to the collections of cut flowers, which were very numerous and good. Dahlias were especially fine. In the class for twenty-four blooms of dissimilar varieties Mr. Anstiss, Brill, was first with superb specimens

of excellent varieties; the blooms were of good size, admirable form, and clear rich colours. The most remarkable were Prince Bismarck, Annie Neville, Christopher Ridley, Monarch, and Michael Saunders. Mr. Tranter, Assenden, followed very closely with nearly equally fine blooms. Mr. Jackson, nurseryman, Kidderminster, obtained an extra prize for good samples. In the class for twelve fancy varieties Messrs. Anstiss and Tranter were the prizetakers in the same order with very fresh blooms. The best dozen French Asters were from F. Barry, Esq., Windsor (Mr. Brown), neat blooms; J. Hargreaves, Esq. (Mr. Turton), being second, and Mr. Phippen taking an extra prize. German Quilled and Cockade Asters were exhibited by Messrs. Brown, Benhill, and Phippen in fair condition. For twelve cut Roses J. T. Strange, Esq., Aldermaston Court, was first with neat blooms, and Mr. Tranter was a very close second. For six Roses Mr. Strange and Mr. Anstiss were the prizetakers. Miscellaneous cut flowers were well shown by Messrs. Phippen, Jackson, Burbridge, and Bezant. In the table decorations and bouquets Mr. Phippen and Miss H. S. Phippen were the most successful competitors, staging several tasteful arrangements.

FRUIT.—The entries in all the classes devoted to fruit were numerous, the quality satisfactory, and the competition in several cases was very keen. The principal class was that for a collection of eight distinct kinds, in which the first prize consisted of a silver cup value £5 5s., offered by Messrs. Sutton & Sons. This was awarded to Mr. Howe, gardener to Sir R. Sutton, Bart., Benham Park, who staged excellent examples of well-grown and matured fruit. They comprised Black Hamburgh and Muscat of Alexandria Grapes, the former even and well coloured, the latter of medium quality; Royal George Peaches, excellent both in size, colour, and ripeness; Morello Cherries of good size; Pitmaston Orange Nectarines, well ripened, handsome fruits; a fine Read's Scarlet-flesh Melon, a neat Queen Pine, and even well-ripened Brown Turkey Figs. Mr. Austin, gardener to Sir Greville Smyth, Bart., Ashton Court, followed with neat examples of Black Hamburgh and Bowood Muscat Grapes, fine Barrington Peaches, well-ripened Pine-Apple Nectarines, and good Bananas among others. Mr. Atkins, gardener to Colonel Loyd Lindsay, Lockinge Park, was third with Viard Apricots and a Lockinge Park Melon in satisfactory condition. For a collection of six kinds Mr. Mortimer, gained the premier award with fine Black Hamburgh Grapes, ripe Moorpark Apricots, and an excellent Cox's Golden Gem Melon. The second position was obtained by the Rev. H. Golding, Holme Park (Mr. Osborn); a dish of Morello Cherries being the most noticeable feature of his collection. Miss Paterson, Bracknell (Mr. J. Tomlin), was a close third. For a collection of four kinds "grown in the open air," R. Ravenhill, Esq., Fernhill, Windsor (Mr. Wells), was first with fine Morello Cherries and ripe Shipley Apricots. Mr. Bridgeman was second with good Moorpark Apricots; and Mr. Lockie third with Morello Cherries and Brown Turkey Figs in fair condition.

GRAPES.—Four classes were devoted to these, and some very fair examples were staged. In the class for three bunches of Black Hamburgh Mr. Ashby was awarded the chief prize for large handsome bunches, the berries being fine, even, and well coloured. Mr. Howe followed very closely, and Mr. Tomlin took the third prize with smaller but neat bunches. For a similar number of bunches of any other black variety there were six entries, the chief honours being secured by H. Harris, Esq., Micheldever (Mr. E. Crump), with grand bunches of Alicante, remarkably well coloured. Mr. Ashby was a good second with Madresfield Court in fine condition; Mr. Mortimer taking the third position with Alicante of fair size but only moderately well coloured. Mr. Mortimer, Mr. Ashby, and Mr. Ross were first, second, and third respectively with Muscat of Alexandria, all showing fair examples. For three bunches of any other white variety Mr. Wells was first with Buckland Sweetwater, well ripened; Mr. Atkins second with Foster's Seedling, fair; and J. Hargreaves, Esq. (Mr. Turton), third with the same variety.

Nectarines, Peaches, and Apricots were very abundant, about twenty-five dishes being staged in the three classes. The most successful exhibitors were Messrs. Osborn and Bridgeman. Messrs. Howe, Ross, and Atkins carried off the prizes for Figs in the order named, all with well-ripened fruit. Plums were shown by Mr. Bridgeman and Mr. Robinson, Cooper's Hill, in fine form; while among the nineteen Melons exhibited the best were from Mr. Atkins, The Gardens, Hampstead Park, and Mr. Lockie, who gained the first, second, and third prizes in that order with fine fruits. In the three classes for Apples about ninety dishes were staged, most of the culinary Apples being of fair quality. The chief prizetakers were Dr. Wells; J. O. Cooper, Esq., Calcot; and G. Palmer, Esq. Tomatoes were fine and abundant, the best being from Messrs. Ross, Jackson, and Atkins. A seedling Melon, raised and exhibited by Mr. Atkins, was awarded a first-class certificate. The exterior was of a rich golden colour thickly netted with white. The flesh was white and of fine flavour. We understand that Messrs. Sutton have purchased the entire stock of this Melon. Vegetables were well shown by several exhibitors, the chief prizes being taken by Messrs. Ashby, Howe, Miller, Locke, and Atkins. The first prize for kidney Potatoes was awarded to Suttons' Woodstock Kidney in a strong competition.

Among the miscellaneous exhibits were extensive collections of cut flowers from Mr. C. Turner, Slough, including superb Dahlias and Carnations, plants of *Bouvardia Hogarth* and *Vreelandii*, Roses, and Zonal Pelargoniums. Mr. H. Cannell, Swanley, Kent, sent stands

of Verbena and Zonal Pelargonium blooms in their customary bright condition.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, Dr. Denny in the chair, the following gentlemen were elected Fellows of the Society:—Frank R. Cheshire, Lieut.-Col. W. H. Moffatt, Charles Oetzmann, and Mr. Herbert R. Peel (of Hemel Hempstead).

— THERE is now a handsome display of DAHLIAS in Mr. Charles Turner's nursery at Slough; Show, Fancy, and Pompon varieties being admirably represented. Of the two former the most noticeable are Mr. Spofforth, a grand, symmetrical, rich crimson bloom; Thomas Goodwin, deep maroon; Grand Sultan, rich crimson streaked with yellow; John Bennett, very distinct, with yellow florets tipped with glowing scarlet; Helen Macgregor, fine pale purple, tipped with a darker shade; and Lady Gladys Herbert, the florets tipped with warm crimson of a brighter shade within. Of the Pompon varieties the most distinct and attractive are the following:—North Light, fine bright scarlet; Lady Blanche, pure white; Julius Kohler, fine purple; Crimson Beauty, a deep crimson maroon; Toby, rich crimson; and Prince of Lilliputians, deep maroon. These and many more are now in fine condition, the richness of the colours and symmetry of the blooms being all that could be desired.

— THE value of BOUVARDIAS HOGARTH and VREELANDI is well shown in the above Nursery, where these two forms are extensively grown. The former as a red, and the latter as a white variety, can scarcely be excelled in floriferousness and general good constitution. Vreelandi is especially notable for the large clusters of long pure white flowers it bears, and in compactness of habit it can be favourably compared with the majority of varieties now grown.

— THE LIVERPOOL HORTICULTURAL ASSOCIATION have decided upon holding an Exhibition of fruit, plants, and Chrysanthemums in St. George's Hall. We hope under the management of this new Society, the Exhibition of Chrysanthemums once so familiar in Liverpool, will again be thoroughly established and will number as one of the principal autumn shows of Great Britain. Schedules are being prepared, and as soon as the date is fixed it will be announced in the advertising columns.

— A FINE old plant that is rarely seen at flower shows—namely, GLORIOSA SUPERBA, was staged by Mr. Mould of Pewsey at the Reading Exhibition on Thursday last. The specimen was trained in globular form, was in vigorous health, and bearing its peculiar but attractive flowers in profusion. It is not often that a formally-trained specimen looks so well as the one in question, but when climbing up the roof of a stove it is extremely ornamental, and is by no means so frequently seen in cultivation as might be expected and desired.

— AN experienced cultivator writing on the WEATHER & POTATOES states that he has no remedy for wet weather, which causes the disease; but what causes him surprise is the extraordinary manner in which people let fine weather pass away without taking advantage of it for securing the bulk of their crops. Like Mr. Luckhurst (see page 162) our correspondent has, by closely watching for the signs of the disease, and prompt action in lifting the crops, secured a fine yield of clean produce.

— A CORRESPONDENT states that "The VICTORIA REGIA IN

THE BOTANIC GARDENS, MANCHESTER, is now in extremely fine condition, the leaves being of great size and completely filling the tank; the flowers also are large and their fragrance most powerful. It has scarcely ever been in better condition, although the quadrangular tank is not well calculated to show it to the best advantage, as the leaves cannot spread equally from the centre. The health of this fine aquatic appears to be due to the fact that the house has a low roof, and the plant thus has the full benefit of all the light possible."

— A CORRESPONDENT writing to us under the heading of an EXTRAORDINARY ESPALIER PEAR, states that there is at the residence of Edward Mewen, Esq., Northiam, Sussex, a Jargonelle Pear tree of very large size. The wall is about 8½ feet high, and is well and regularly clothed with boughs apparently in good health for a distance of 30 yards. The main stem of the tree is rather flattish, and is fully 2 feet across. It bears sparsely, being exposed.

— IN one of the houses at Messrs. Sutton & Sons' Nursery, Reading, some hundreds of plants of a NEW TUBEROUS BEGONIA are now flowering. The variety is the result of a cross, and evidently partakes to some extent of the Pearcei type. The flowers are very large, in several instances more than 3 inches in diameter, of a fine pale primrose tint when first opening, ultimately fading to nearly white, and they are produced in astonishing profusion. The foliage varies in colour and markings; the leaves on some plants being very dark green and finely marbled white, on others they are of a uniform green tinge. It is a remarkable circumstance that five hundred plants raised from seed borne by one specimen should resemble each other so exactly in every respect except the colouring of the foliage. It is a useful attractive variety, one of its most valuable qualities being the freedom and continuance with which the flowers are produced. The delicate pale yellow hue of the flowers was shown up to the best advantage by a row of Vallotas placed along the back of the stage.

— AN attractive hardy plant and one of the best of the genus is MONARDA FISTULOSA PURPUREA, which, though not possessing the brilliant colour of M. didyma, is yet rendered very showy by the large terminal heads of bright purple flowers that are so freely produced. A good companion for the above variety is M. Russelliana, which has white flowers very faintly tinged with pink. There is also a white form of M. fistulosa.

— IN recognition of his valuable services as Manager and Secretary of AMIES' CHEMICAL MANURE COMPANY, Mr. G. Neilson Tucker has been elected Managing Director of that Company.

— A RECENT issue of the *Irish Farmers' Gazette* has the following concerning a MONSTER PEACH:—"A fruit of Lord Palmerston Peach, grown in Col. Jones' garden at Templeogue this season, was quite a wonder in its way. It weighed 17 ozs., and girthed somewhere about 11 inches. The tree, which is about four years planted, besides this mammoth fruit, bore a goodly crop of choice Peaches, each averaging from 10 to 11 ozs. Have any of our readers met with a Peach the weight of which was in excess of the above?"

— THOSE handsome herbaceous plants ANEMONE JAPONICA AND JAPONICA ALBA are now in splendid condition in many gardens, but we never saw them finer than they are in a garden west of London. Two long beds about a yard in width were entirely occupied with the rosy-flowered species and its white variety, and they could only be adequately described as a mass of flowers. The white form was especially fine, the blooms being uncommonly large, of great substance, and of the purest white, with the exception of a slight orange-coloured ring in the centre.

— WE learn that the ROYAL HORTICULTURAL SOCIETY OF IRELAND will hold its autumn Show on September the 2nd.

— IN the tank devoted to hardy aquatic plants at Kew that lovely little Pondweed, *APONOGETON SPATHACEUM* VAR. *JUNCCEUM*, is now flowering. It has small round rush-like leaves, 6 or 7 inches high, and produces a scape of about the same length, divided at the apex similarly to the well-known *Aponogeton distachyon*, but considerably smaller. The flowers and bracts are white with a purplish tinge. The plant succeeds well outside during the summer, but is safer in a frame or other cool place during winter.

— RELATIVE to the SCARCITY OF POTATOES in the spring, we learn that during the first six months of the year there was a deficiency in their carriage to London by the Great Northern Railway alone of 21,237 tons.

— A CORRESPONDENT states, "that in the WINTER GARDEN OF THE SUNDERLAND PARK, specimens of *Pandanus Veitchii* and *Dracæna congesta* are producing vigorous spikes of flowers. *Cobæa scandens* and *Tropæolum Lobbianum* cover the roof and produce a beautiful display of flowers."

— IT having been agreed that a testimonial of respect should be given to Mr. PETER GRIEVE, for thirty-one years head gardener to the Rev. E. R. Benyon, of Culford in the county of Suffolk, a Committee has been formed for carrying out the object, and the horticultural public is requested to join in honouring the "father of the tricolor Pelargonium." Donations can be forwarded to Mr. Joseph Harrison, Treasurer and Secretary, Bury St. Edmunds.

— "B." WRITING from Uxbridge says—"I find the Alpine Enchanter's Nightshade, *CIRCÆA ALPINA*, very ornamental among other herbaceous plants at this time of year. I have a fine tuft of it more than a yard in diameter, in a somewhat sheltered part of the border; and although the individual flowers are very diminutive, the short racemes on which they are borne are produced in such great numbers that the foliage can scarcely be seen. The white corollas, too, are relieved by the reddish calyxes and peduncles. A moderately sheltered position that is not too damp suits it admirably."

ROYAL HORTICULTURAL SOCIETY.

AUGUST 24TH.

THE chief features of this meeting were the Dahlias and Gladioluses, which alone constituted a brilliant display. Several other collections of plants were also exhibited, all more or less interesting, and the display was both bright and attractive.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. W. Elphinston, gardener to E. M. Mundy, Esq., Shipley Hall, Derby, was awarded a cultural commendation for three bunches of Golden Queen Grape weighing 12 lbs., and fairly ripened. From the Society's Garden at Chiswick fruits of Bergamotte Auguste Jurie Pear were sent, for which a first-class certificate was awarded as an early variety. Mr. G. Williams, gardener to C. Liddell, Esq., Pensmarsh Place, Sussex, sent six plants of Black Hamburg Grapes in pots for table decoration. Each plant was bearing a bunch of well-coloured Grapes, one bunch being of great size. They were in 32-size pots. A cultural commendation was awarded. Mr. D. McLaurin, The Garden, Farnbro' Hill, sent samples of Hyde's Seedling Melon, which was characterised by the Committee as not so good as many in cultivation. Mr. W. Hinds, The Gardens, Canford Manor, Wimborne, sent a box of Improved Trophy Tomatoes, fine in form and colour. A Plum named John Powell from Mr. C. Turner of Slough was not considered superior to others in cultivation. Messrs. Thomas Rivers & Son, Sawbridgeworth, sent fruits of Dryden Nectarine, which were found rather tart in flavour. Mr. W. Iggulden, The Gardens, Orsett Hall, Romford, sent fruits of Tomato Trophy grown without fire heat. The fruits were of great size, excellently ripened, and well coloured. Herr Ernst Benary, Erfurt, sent a dish of white Tomatoes. Mr. J. Woodbridge, The Gardens, Sion House, sent Alnwick Seedling Grapes, for which a letter of thanks was accorded. Mr. Elphinstone, Shipley Hall Gardens, sent fruits of the Melon "Luscious and Melting."

A collection of fruits of the Egg-plant was sent from Chiswick comprising thirteen varieties, white, purple, yellow, and scarlet. A collection of about one hundred Capsicums was also sent from Chiswick. A first-class certificate was awarded for a variety named Yellow of Nocerd, a peculiar three-lobed fruit.

Special prizes were offered by Messrs. Freeman & Freeman of Norwich for their Melon "Luscious and Melting," and their "Champion" Cucumber. In the former class Mr. J. Coomber, gardener to J. A. Rolls, Esq., M.P., Hendre Park, Monmouth, was awarded the prize for a handsome well-ripened fruit. There were four entries in the class for Cucumbers, the successful exhibitor being Mr. C. Howe, Benham Park, Newbury, with two fruits, one 22 inches and the other 24 inches long, of admirable form and having fine bloom.

Messrs. Smith & Larke, florists, High Street, Kensington, sent a sample of Oats grown on a piece of very poor land to which a dressing of Clay's fertiliser had been applied at the rate of 3 cwt. per acre, no other manure having been put on the land for some years. The sample was of great weight, and a vote of thanks was accorded.

FLORAL COMMITTEE.—Dr. Denny in the chair. Messrs. Kelway and Sons' (of Langport) collection of Gladioluses formed the chief feature of the meeting. About eighty spikes were staged, comprising a very large number of excellent varieties. A great diversity of colours were shown from pure white to the richest scarlet. The flowers were of great size and closely placed in the spikes. Some of the best varieties were the following:—Anthony Waterer, crimson, white streak; Dr. Woodman, pale salmon, purple tinge in lower petal; Antisthenes, fine scarlet; Opiter, crimson streaked margin, light centre; Ball of Fire, glowing scarlet; Queen Mary, white, fine, purple streak in lower petal; Calliophon, fine rosy pink streaks; and Mr. Derry, pale purple. They also exhibited seedling Dahlias and Asters. The Asters were represented by a number of large blooms, white, crimson, and purple being especially fine. A gilt Flora medal was awarded for the Gladiolus.

Messrs. Veitch & Son, Chelsea, sent a collection of Orchids and rare plants. The most noticeable were *Aristolochia ringens*, a species with neat, small, reniform leaves, and medium-sized flowers thickly veined and marked with dark maroon. *Sigmatostalix radicans* was a pretty dwarf Orchid with narrow grass-like leaves, and racemes of small flowers with pale green sepals and petals and white labellum. *Oncidium ornithorhynchum album* had panicles of white flowers with comparatively large yellow crests on the labellum. *Dendrobium bigibbum superbum* had neat flowers, pale purple, purplish crimson labellum. *Zygopetalum Wendlandi*, a species from Costa Rica, had a single flower with pale green sepals and petals, and a purplish labellum. Messrs. Veitch also sent about thirty immense trusses of *Hydrangea paniculata grandiflora*, which were especially remarkable for the large number of medium-sized white flowers crowded in the panicles. Some of the latter were about 10 inches in height and the same in diameter. Mr. B. S. Williams, Upper Holloway, sent a collection of new plants. Among these were a specimen of *Mormodes pardina*, with yellow flowers, the incurved petals and sepals being spotted with claret. The flowers are borne in a short raceme, and possess a peculiar drug-like odour. *Lælia elegans prasiata* was noteworthy for the rich purplish crimson of the lip, and the dull purple sepals and petals. *Zygopetalum Gauteri* had pretty flowers somewhat resembling *Z. Mackayi*.

Messrs. James Carter & Co., High Holborn, sent specimens of the Empress Cockcomb, with extremely large heads of a deep rich crimson colour. A vote of thanks was accorded for these plants, which we learn were grown by Mr. Bridgeman, gardener to T. Somers Cocks, Esq., Great Marlow. Messrs. Rawlings Bros., Romford, sent several new Dahlias, Sir Stafford Northcote being noticeable for its fine form, great depth, and regularity, the colour being bright scarlet. C. Harris was of excellent form, deep crimson maroon; and Shirley Hibberd similar, but darker in colour and rather rough. C. Sh. field was a neat flower, purple and white. Messrs. Keynes & Co., Salisbury, exhibited some very handsome Dahlias, of which James Vick, deep purple; Walter William, bright scarlet; Lady Wimborne, bright pink; Mr. Compton, purplish maroon; and Mrs. Dodds, pale purple with lighter centre, were the best. Mr. Cullingford staged a collection of single Dahlias grown at Kensington, comprising many handsome scarlet, yellow, and maroon varieties. Mr. H. Cannell, Swanley, Kent, exhibited cut flowers of *Pyrethrums* from plants that had previously flowered early in the season; *Petunia*; *Zinnias*, *Tigridias*, and a single specimen of the fine *Cactus Dahlia* (*D. Juarezii*), all of which were in the fine condition that usually characterises the products from Swanley. Mr. A. Waterer, Knap Hill, Woking, sent flowers of *Lilium Parkmanni*, a handsome form with crimson spotted flowers. Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, sent a plant of *Stephanotis floribunda* of the Elvaston variety, which was very profusely flowered. The strain was commended.

Mr. Charles Turner, Slough, exhibited a number of handsome Dahlias, of which several were honoured with first-class certificates. Show, fancy, and Pompon varieties were well represented. A fine collection of Pompon Dahlias was sent from the Society's garden at Chiswick, a large number of handsome varieties being represented. A vote of thanks and a bronze Banksian medal were awarded to Mr. H. Boller, Kensal New Town, for a collection of *Mamillarias* and *Echinocactuses*, *Echinocactus scopa* being fine. Messrs. Sutton and Sons, Reading, sent a collection of their new Hybrid Tuberous *Begonias* referred to in another column. A vote of thanks was accorded, and the strain was commended.

First-class certificates were awarded for the following plants:—

Gladiolus Opiter (Keynes).—A very handsome variety. Large flowers, the tips and margins of the perianth division being streaked with crimson, the centre being lighter. *Aquinus*.—Rosy crimson,

with a few dark streaks and spots. Flowers large; spike massive. *Anthony Waterer*.—Bright scarlet, with streaks down centre of division. Flowers neat; spike large. *Pilumnus*.—Enormous flower, white, with a very slight tinge of purple and a few streaks; a most delicate tint. *Calliophon*.—Streaked with bright rose, lighter centre, and lower division stained with yellow. *Phormis*.—Flower very large, streaked with two shades of crimson.

Dahlia Revival (Turner).—A handsome show variety of great symmetry, moderate size, great depth, and very deep scarlet. *Queen of Spain*.—A fine flower of a peculiar yellowish tinge, with a few purplish streaks. Very good form. *Goldfinder*.—A grand yellow variety of excellent form. Colour very bright and clear. *Dr. Ranch*.—A Pompon variety, very neat; the flower 1 or 1½ inch across, of a

reddish tinge. *Professor Klug*.—Also a Pompon; pale pink. Very pretty. All the above, except the Pompon varieties, were raised by Mr. Fellowes.

Dahlia Lady Wimborne (Keynes).—A rich deep pale rose-coloured show variety; very clear and symmetrical. *James Vick*.—An admirable variety, deep purple, and very symmetrical. *Mr. Compton*.—An exceptionally handsome show variety, of excellent form, and deep purplish maroon in colour.

Lilium Parkmanni (Waterer).—A beautiful form with large flowers; the centre of the division very rich crimson, spotted with a darker shade, the margin being white.

Bolbophyllum Beccari.—A botanical commendation was awarded to Messrs. E. G. Henderson & Son, Maida Vale, for a specimen of this

Fig. 43.—EUCRYPHIA PINNATIFOLIA.

peculiar Orchid. It had enormous leaves, nearly a yard in length and over 2 feet in breadth, and was bearing a spike of small dull-coloured flowers, that possess a most offensive odour.

During the afternoon F. Cheshire, Esq., continued his lecture on bees, the subject then discussed being "The Modern Inventions which have for their Object the Assistance of Bees in Storing Honey in Purity for the Benefit of Man." The lecturer most entertainingly explained the construction of comb and the advantages of employing artificial foundations. The modern mode of extracting honey was also fully treated on, the superiority of the present system as compared with that formerly practised being illustrated at length. A vote of thanks was unanimously accorded to Mr. Cheshire at the conclusion of the highly interesting and instructive lecture.

EUCRYPHIA PINNATIFOLIA.

ONE of the most beautiful shrubs of recent introduction is that represented in the annexed engraving, which fairly indicates the

general character of the foliage and flowers. The species has been in this country for the past three or four years, but was first exhibited by the introducers, Messrs. Veitch & Sons, at the meeting of the Royal Horticultural Society on August 10th, when a first-class certificate was awarded for it. The sprays submitted to the Floral Committee and that represented in our engraving were gathered from specimens of the shrub growing in Messrs. Veitch's nursery at Coombe Wood, where it proves quite hardy and flowers most profusely. It is unquestionably a grand addition to our list of really ornamental shrubs; and being hardy, at least in the south of England, is also a great point in its favour, and further north, where possibly it may not endure the winters unprotected, it could be successfully grown in a conservatory or winter garden.

Eueryphia pinnatifolia is one of a small number of species constituting a genus that is represented in both Chili and Australia; but the one now described is a native of the former country, where it has been found in various rocky districts, but is rather scarce.

The flowers are large, pure white, and usually borne in pairs near the upper portion of the branches, affording an agreeable contrast to the dark green pinnate leaves. The stamens are thickly clustered in the centre of the flowers, and that character combined with the form of the flowers is somewhat suggestive of the Mock Orange. These blooms also possess a powerful and pleasant fragrance. This shrub is likely to obtain a permanent place in the gardens of this country when its merits become more generally known.

THE SCOTCH CHAMPION POTATO.

MR. LUCKHURST is a bold man to tell the world that he will discard the Potato which attained such celebrity last year, that, in popular parlance, everybody was "running after" seed of it early this season. Two things occurred to me in reading the observations on page 162. First, has your correspondent the true variety? secondly, if he has, has he not been rather premature in denounce it? I have grown and eaten two forms of the Champion. There is not much difference in their appearance when growing, but when the tubers are cut one is "decidedly yellow," the other only suspiciously so, and when cooked the tubers of one are yellow and sad, those of the other being white and floury. The cooking of both was done in the spring, which is the season for the Champion; and it is about as hasty to denounce it now as it would be unreasonable to complain of the quality of the Old Ashleaf in March. If the Scotch Champion is "decidedly inferior," how comes it that it was awarded a first-class certificate by the Royal Horticultural Society for excellence of quality, after it had been submitted in a cooked state? This is essentially a late Potato, its period of use being March to June, and August is not the proper month for estimating its culinary merits.

Those are fortunate who can insure good and sound crops of York Regents and Victorias for late use; but thousands were unable to do so last year, and, in some parts of Ireland at any rate, they will be in much the same position this season. It is not with such cultivators a question of Champions *v.* Regents, but rather of Champions and Magnum Bonums or no Potatoes. These varieties have proved of great value in low-lying and wet districts; but it is a question if they would be half so profitable in dry localities during a hot summer, therefore I should never grow them exclusively.

"A LINCOLNSHIRE GROWER" on page 158 appears to have found out, I was going to say a weak, but I suppose it is a strong point, of the two celebrities. He says they are "terrible soil-exhausters." Their luxuriant growth and couch-like roots take out, perhaps, twice the manurial elements from the soil that some other varieties do. I have just been examining a piece of Wheat that followed Potatoes, one half of the ground last year being Regents, the other half Champions. There will be a great difference in the yield of Wheat from the two halves of this plot, the growth on the Champion half being altogether lighter and the heads smaller than on the other. In stating the "Champion" half as the lightest, I perceive I have committed a "bull." It is, however, I presume, quite appropriate, for I am—AN IRISHMAN.

LEE HALL,

THE residence of J. H. Wilson, Esq., is situated at Gateacre, six and a half miles from Liverpool. It is easy of access, the main drive being in close proximity to Gateacre station. The gardens are reached by traversing the drive through the park, which is rather extensive, and contains some good forest trees, such as Limes, Horse Chestnuts, and Elms. The trees stand separately, and have developed into symmetrical specimens. The glass is the principal object, and includes a range of vineries divided into three compartments. In front of these vineries is a low house, which entirely covers the border in which the Vines are growing. Tomatoes were growing on the back portion of this house, while on the front stage we noticed good specimens of that beautiful and popular Carnation *Souvenir de la Malmaison*. *Amaryllises* were growing in quantity, all seedlings of continental origin. The best have been selected when in flower and hybridised, and many seedlings have been raised by Mr. Glover, the gardener. The stove is a good-sized house and contained a miscellaneous assortment of plants, including a fine *Goniophlebium appendiculatum*, *Cycas revoluta* in good condition, and a handsome *Sobralia macrantha*. *Stanhopeas* and other suitable plants in baskets were suspended from the roof. The house devoted to *Azaleas* is 66 feet long and 18 wide. The centre bed was filled with large specimen and half-specimen plants. The back stage was filled with small plants of *Azaleas*, principally semi-doubles. The front was filled with *Heaths*, *Epacris*, and other New Holland plants. *Camellias* occupied three houses. A few years ago the plants were tall and

leggy; they are now fine, healthy, symmetrical bushes in pots. The majority of them have been cut close back and allowed to break again. The result in this case was good, and no better system can be adopted when *Camellias* become straggling. After being cut down the plants were allowed to develop into bushes—much better than twisting and pulling them into some formal shape. The *Camellias* have heat only to keep out frost, and Mr. Glover contends that when plants are healthy and vigorous heat is not necessary to secure a good set of bloom unless early flowers are required. Shading is employed during the hottest part of the day, and the plants bloom well. On the back stage of the *Camellia* house some *Chrysanthemums* in 3-inch pots were in bloom the last week in May, and the last of a supply from November. The cuttings were struck late in the autumn from plants growing in the shrubbery borders. It is evident that the flowering season of this most beautiful of winter plants could be extended over a much longer space of time during winter and spring if cuttings were struck late as in this case. I noticed in a lean-to house with a northern aspect some large Sikkim *Rhododendrons* and many plants of *Cacti* coming into flower. The conservatory is 50 feet by 28, and was gay at the time of my visit with *Azaleas*, *Mignonette*, *Erica Cavendishiana* two very good plants, *Roses*, *Intermediate Stocks* in pots, and the usual assortment of flowering plants. There is no stage in the centre, and the plants employed for the centre group can be conveniently arranged to produce the greatest and most pleasing effect. *Fuchsias* are trained under the roof, single rods, which run to the top of the house, and are at pruning time spurred-in like Vines. They are in tubs, which they have occupied for about fourteen years, although rich surface dressings have been applied annually.

The great feature of Lee Hall gardens is the grand collection of Orchids, so well known round Liverpool. It is by far the most extensive and complete collection in the neighbourhood. I may say nearly all have been small imported pieces to start with and are now grand plants, and some of them have proved to be varieties of superior merit. The first house is 30 feet long and 13 wide, span-roofed, with walk up the centre. This house is kept cool, and the *Cattleyas* are placed in it while in bloom. Nine good plants of *C. Mossiae* and its varieties were in bloom, also a fine dark variety of *C. Mendellii*, *C. Forbesii*, and *C. amethystoglossa*. A good plant of the pretty *Colax jugosus* was flowering freely. Several good specimens of *C. barbatum* were well bloomed. *Maxillaria grandiflora* had forty-five spikes of bloom. Many plants of *D. nobile*, *D. pulchellum*, *D. Devonianum*, *D. chrysanthum*, and *D. crystallinum* were in flower. The *Anguloas* were much stronger than any I have had the pleasure of seeing for some time past. *Oncidiums* were well represented, and amongst the best in bloom were *O. sarcodes* with a fine branching spike of yellow and crimson flowers; *O. stelligerum*, *O. cucullatum majus*, *O. macranthum*, a grand Orchid producing a branching inflorescence several feet in length; and *O. ampliatum majus*, a very fine variety. The adjoining house was devoted to *Odontoglossums*, *Masdevallias*, &c., and was very bright with many varieties in flower. Most conspicuous were the large-flowered *O. vexillarium*, *O. cirrhosum*, *O. Pescatorei*, *O. Alexandræ*, *O. gloriosum*, *O. nebulosum*, *O. secp-trum*, *O. Hallii*, *O. triumphans*, *O. luteo-purpureum*, *O. maculatum*, *O. Dawsonii*, and the rare and beautiful *O. cordatum* were in grand health and blooming freely. A hybrid *Odontoglossum* was also in flower, and appeared to be a cross between *O. luteo-purpureum* and *O. Lindleyanum*, possessing the lip of the former. *Masdevallias* were very robust and well bloomed, and added greatly to the effectiveness of the house. *M. Veitchiana* was very fine; *M. amabilis*, *M. ignea*, and *M. ignea splendens* were in good form; *M. ignea violacea*, *M. Lindeni*, *M. Harryana* and its variety *splendens*, and *M. sanguinea superba* were also in bloom. *Epidendrum vitellinum majus*, *Mesospinidium sanguineum* were bright in baskets, and *Odontoglossum Cervantesii* and *Leptotes bicolor* were suspended in numbers from the roof and flowering abundantly. The secret of Mr. Glover's success with species requiring cool treatment is in maintaining a very cool airy temperature and supplying abundance of water. During winter the frost on many occasions was only just excluded from the house, and the plants did not suffer in the least. Their appearance at the present time sufficiently indicates that the plants thrive with the treatment they receive from Mr. Glover.

The *Cattleya* house is 66 feet long and 18 feet wide, and the centre stage is entirely filled with good plants of *C. Dowiana*, *C. gigas*, *C. crispa*, *C. labiata*, *C. Mendellii*, *C. Skinneri*, *C. Warneri*, and other leading and popular varieties. This house was rendered bright with quantities of *Anthurium Schertzerianum* in bloom arranged amongst the *Cattleyas*. In fact all through the Orchid houses quantities were in bloom, and nearly all seedlings that Mr. Glover has raised. Those in the intermediate houses were stronger

and finer than those grown in the hottest houses. The next and last is the East Indian house, and is only separated from the above house by a glass partition. The first plant that attracted attention was *Hoya imperialis* in flower, a plant seldom seen in private places. The house contained some good Vandas; a piece of *V. tricolor* was in flower, also *Saccolabium ampullaceum*. *Aërides* was represented by good plants, and *Cypripediums niveum* and *Hookeræ* were in bloom. *Sonerilas* and other dwarf-growing plants of a similar nature were growing amongst the moss with the Vandas, *Aërides*, &c., which looked neat and effective.

The grounds were in good order, and the flower garden and shrubbery borders gay with spring-flowering plants. Mr. Wilson is a great Orchid enthusiast and lover of horticulture. Mr. Glover, like his employer is equally so, and a most successful cultivator.—WM. BARDNEY.

FLORAL DEFENCES.

(Concluded from page 161.)

Path-pointers.—Sometimes Nature fulfils the old adage of killing two birds with one stone, and uses her floral palisades as path-pointers to direct the welcome visitor to the nectar. One of the most exquisite examples of a structure serving such a double purpose may be found in the Grass of Parnassus. Five of the ten stamens are transformed in such a way that their broad bases bear rows of finger-like organs, each with a little yellow knob at the tip. The knobs are not glandular, at all events they do not form a sticky secretion. The nectar is found at the base of the stamens on the inside next the pistil.

Botanists have been very much puzzled what to make of these gold-tipped claws. They have been called staminodes, imperfect stamens, scales, nectaries.

In the charming blossom known as Passion-flowers protection is afforded in quite a different manner. A floral appendage, answering to the yellow centre in the Polyanthus Narcissus and called the corona, is divided into a double or a triple fringe, forming a diadem around the anthers and the curiously shaped pistil. No creeping thing can pass through such a zone, the loveliness of which seems as if designed to attract a humming-bird or a butterfly.

It is sad that a friendly insect should ever have recourse to partaking surreptitiously of hospitality which would willingly be accorded if sought in a friendly way. But truth requires the admission that certain bees, otherwise accustomed to conduct themselves with propriety, are in the habit of setting all order and etiquette at defiance by biting through the tubes of flowers just above the nectary, thus plundering the blossom of its sweets without coming into contact with the stamens or the style.

Against such a burglarious entrance certain flowers are defended by a calyx resembling an inflated bladder, in the centre of which rises the tube of the flower. The bee may bite through the calyx but cannot reach the nectar, and it is probable that flowers thus defended are very rarely attacked. The distended calyx also serves for the distribution of the seeds by the wind.

There are many flowers unprovided with any of the foregoing appliances or means of defence which we have been considering. We speak of animal sagacity, and there is something which may be called floral sagacity in the way by which one unprotected flower is secured from

molestation. It is one of the Touch-me-nots, common in the forests of Germany. The flowers are full of nectar and are attractive to bees, which are welcome visitors; but the mode in which ants and other creeping things are kept away is singular. In the place of stipules at the bases of the leafstalks on the stem, the plant develops small saucer-like receptacles which are kept full of honey. Dr. Kerner writes—"Any insects that creep along the stem must, if they would get at the flower, of necessity pass over this deposit of honey; thus what they would have sought, and moreover would have found in the flower, is already offered them below in rich abundance. The creeping insects are not fastidious. Nectar in one place is the same to them as nectar in another. They are content with that which is first offered, and so do not trouble themselves to climb further up to the flowers." Dr. Kerner has seen three ants feeding together at the honey on the stem, but though he has examined hundreds of plants, he has never seen a single ant reach the blossom.

In a short notice of Flowers and their Unbidden Guests, which I wrote for one of the Liverpool papers, and which it is possible that some of you may have seen, I mentioned that towards the close of Dr. Kerner's volume

Fig. 44.
Stem and Honey-saucer
of the Touch-me-not.

occurred two charming plant stories like drops of honey at the bottom of a flower. The substance of one of them will serve for our last illustration. It may be called the life-history not of a plant but of a single blossom, a blossom of the Nodding Catchfly, which,

however, does not seem to be the *Silene nutans* of the English Flora.

Night-flowering plants, such as the Evening Primrose, last but a short time in flower, usually one night only. A single blossom of the Nodding Catchfly, however, remains three nights and two days in perfection, and observes, in the opening and closing of the different parts of the flower, an order more like the result of intelligence than of mere vegetable growth. On the first evening the flower expands about eight o'clock, and remains open far on into the night. Of its ten stamens five push themselves boldly in advance of the petals, which fall back upon the calyx, displaying the pure white of their upper surfaces. At the same time the anthers open and are richly covered with fresh pollen. The plant now sheds a strong perfume attractive to night-flying insects, which, for some unknown reason, alone are acceptable to the Nodding Catchfly. The following morning the five anthers droop, wither, and finally fall off. The petals roll themselves up so as to exhibit only their dull green undersurfaces, and all emission of perfume ceases. There is now nothing to attract day-flying insects, and the flower is well protected from the visits of ants and other creeping things by viscid hairs on its stem as represented below.

From its old and wrinkled appearance one might think that the flower had withered and shrivelled up. Not so: at the approach of night the wrinkles disappear; the petals show their brilliant white surfaces; again the sweet perfume is spread on the night breeze, and the remaining five anthers come forth fully opened out and laden with fresh pollen. On the second day a similar withering and shrinking of the flower occurs, the anthers of the past night fall away, and no perfume attracts a butterfly or a bee. The floral dis-

CHANGES OBSERVED IN A SINGLE BLOSSOM OF THE NODDING CATCHFLY.
Fig. 45.

guise, for such it really is, continues till the third night, when again the petals expand as fresh as ever, and the perfume flows out freely, this time in favour of the silky pistils, the styles and stigmata of which stand out, as the anthers did before, and are now ready to be fertilised by pollen from flowers in their first or second night's condition.

Marvellous! Why should such an inconspicuous flower have so singular a history? Why should it prefer night-flying insects, and be so excessively coy by day? Why should it put forth five anthers only on the first night, and the rest on the second night? Such questions might be multiplied, and to all of them there can be but one ultimate answer: but in subordination to that answer, and for instruction as to the means whereby so wondrous a life history has been brought to pass, they all point to a theory of development which has been charged with robbing our love for flowers of all its poetry and of half its capacity for affording delight. Surely it has opened for us new resources within the reach of every willing observer.

The life history of our most common British plants has hitherto been very insufficiently traced, and may yet yield rewards far higher than the discovery of new species. One word of caution is needed: we must not suppose that now we have found a way to the bottom of Nature's secrets. A distended calyx may not always be meant for a defence against biting bees. Many flowers seem not disposed for cross-fertilisation, but the contrary, and then, of course, they require no defences; nevertheless they seem to have them: so there is something more to be found out.

I cannot claim much originality in what I have stated. I have mostly described what others have seen; but the line is a promising one, and should we be so far favoured as to meet again in the fields, under sunny skies, I anticipate much pleasure in pursuing the subject with you in the happiest possible way—with the fresh flowers in our hands—all the apparatus requisite being simply a magnifying glass and a pin.

LARGE POTATOES, "FLOUNDERS."—One of the largest and most generally grown early Potatoes in Ireland is, perhaps, the

Flounder. It is, however, comparatively tender, and one of the first always attacked by blight, but its early use and maturity enables it to be consumed before any sensible harm is done by the disease. Here they are an enormous crop. I weighed the produce of one root, six large tubers, rejecting the smaller, and found it to be 7 lbs., one tuber weighing 1 lb. 6 ozs. To-day the largest Potato I ever saw, a Flounder, weighed 2 lbs. exactly.—W. J. M., *Clonmel*.

CRYSTAL PALACE FRUIT SHOW.

THE annual Fruit and Cut Flower Show at Sydenham was opened on Wednesday last, the exhibits being fairly numerous in most of the classes. In those devoted to fruit Grapes were by far the most strongly represented; Peaches, Nectarines, and Pine Apples being also well shown. Cut flowers were abundant and occupied a considerable space. The short time at our disposal only enables us to give the names of the principal exhibitors in the several classes.

In the chief class for a collection of twelve dishes of fruit the first prize was obtained by Earl Somers, Eastnor Castle, Ledbury (gardener, Mr. W. Coleman), with fine bunches of Black Hamburg and Muscat of Alexandria Grapes, the former well coloured and ripe. Lord Napier Nectarines and Bellegarde Peaches of fine size and colour were the most noticeable of the other dishes. Earl Brownlow, Ashridge Gardens, Berkhamstead (Mr. G. Sage), was a good second with fine Peaches. These were the only two exhibitors. For a collection of eight dishes there were five entries, the chief prize being secured by Lord Suffield, Gunton Park, Norwich (Mr. Allan), with well-ripened fruit; R. Leigh, Esq., M.P., Barham Court, Maidstone (Mr. C. Haycock), being a close second; and Lord Calthorpe, Winchfield, Hants (Mr. Thos. Jones), third.

Grapes were moderately well shown, the black varieties being especially fine in the winning collection. In the classes for black Grapes the successful exhibitors were Mr. Roberts, Gunnersbury Park; E. M. Mundy, Esq., Shipley Hall, Derby (Mr. Elphinstone); J. L. Lovibond, Esq., Start's Hill, Farnborough, Kent (Mr. G. Tucker); Mr. Coleman; Mrs. Lambert, Bletchingley (Mr. J. Goldsmith); H. Harris, Esq., Steventon Manor, Micheldever (Mr. E. Crump); and Birket Foster, Esq., The Hall, Witley, Surrey (Mr. F. Jordan). In the five classes there were twenty entries. In the class for ten varieties Mr. Elphinstone was first with good black Grapes, but the white varieties were not first-rate. Mr. Henry Apted, Broadwater, Worthing, Sussex, was second with smaller and less well ripened specimens. Four collections of five varieties were staged, Mr. Allan and Mr. Tucker being the winners. F. F. Halsey, Esq., M.P., Gaddesden Place, Hemel Hempstead (Mr. H. Folkes), was first with the heaviest bunch of Grapes—viz., Trebbiano, 5 lbs. 7 ozs., Mr. Coleman following with a bunch of Black Hamburgs weighing 5 lbs. 6 ozs. White Grapes were poorly represented, Messrs. Folkes, Elphinstone, Coleman, and Allan being the chief prizetakers. Mr. W. Allan sent bunches of a new black Grape named Chatsworth Seedling, which appeared to be distinct and meritorious, the flavour being good, the berries long, and the bunches large.

In the two classes for Pine Apples there were nineteen fruits shown, generally of fair quality and size. The prizetakers for a single fruit of the Queen variety were L. J. Baker, Esq., Haydon Hall, Eastcote Pinner (Mr. J. Fry); and C. R. M. Talbot, Esq., M.P., Taibach, South Wales (Mr. J. Muir). For a Smooth Cayenne Earl Fortescue, Castle Hill, South Molton, North Devon (Mr. David Wilson), was followed by Mr. Muir. Nineteen fairly good Melons were staged in the two classes devoted to them. With scarlet-fleshed varieties Sir W. Farquhar, Bart., Polesden, Dorking, Surrey (Mr. O. Goldsmith), was first, followed by J. T. Drake, Esq., Amersham (Mr. T. Bailey). The Baroness L. de Rothschild, Gunnersbury Park (Mr. J. Roberts), was first with a green-fleshed variety; and W. Spottiswoode, Esq., Coombe Bank, Sevenoaks (Mr. J. Bolton), was second. Nectarines were represented by ten single dishes and three triplets, the prizetakers being in the former Mr. Coleman and Mr. Allan with well-ripened fruits, and in the latter Mr. Coleman and the Rev. W. Sneyd, Keele Hall, Stafford (Mr. Wallis). Peaches were generally fine, Mr. Roberts and Mr. Coleman taking the prizes in a class of seven exhibitors. Plums were moderately good, there being seventeen competitors in two classes; Mr. Bailey, Mr. J. Fry, and Mr. Sage being the prizetakers. Figs were shown by Messrs. Sage, Allan, and Coleman in fair condition.

Cut flowers were numerous and remarkably bright, Dahlias being especially notable. The chief prizetakers in these classes were H. Glasscock, Esq., Bishop Stortford; T. Anstiss, Esq., Brill, Bucks; Mr. H. Cannell, Swanley, Kent; and Messrs. Keynes & Co., Salisbury. Messrs. Kelway & Son, Langport, staged the best collection of twenty-four Gladioli spikes; the Rev. H. H. D'Ombra, Westwell Vicarage, Ashford, Kent, also being first in the class for twelve spikes with remarkably fine specimens. Several tasteful arrangements for table decorations were shown. Messrs. Dick Radclyffe & Co., High Holborn, were placed first; and Mr. Thos. Butcher, Florist, South Norwood, second. Bouquets were also good.

The miscellaneous exhibits were very numerous. Messrs. H. Lane and Sons, Great Berkhamstead, sent some fine specimens of Vines in pots. Messrs. Kelway & Son, Langport, exhibited a fine collection of

Gladioli spikes, also flowers of Dahlias and Asters. Messrs. Carter and Co., High Holborn, contributed a number of Lilliums, Hollyhock blooms, Cockscombs, and Dahlias.

THE POTATO DISEASE.

I SEE by No. 7 of your valuable Journal that "A KITCHEN GARDENER" does not agree with me in my statement that about half the losses by the disease arises from the want of knowledge, &c., of the growers. I do not expect everyone to take the same view that I do, and I should be content to allow this little difference of opinion to pass without comment, but the interests at stake are so vast that I think I should be wrong in doing so. Our losses last year by the disease were estimated at no less than fifteen millions sterling; and this year there is again an outcry about the disease. Are we to go on like this and do nothing? "KITCHEN GARDENER" thinks that everything depends on the weather and the elements, and that we have nothing to do but fold our hands, *à la Turc*, and take what Providence is good enough to send us; and "LINCOLNSHIRE POTATO GROWER" is pretty much of the same opinion. I do not take this view. We have been following a waiting policy for the last thirty-five years, and what good has come of it? It is time to wake up now and do something to lessen these terrible losses. That these losses can be much reduced I know by what takes place every year under my own eyes, so that I cannot be deceived. I am not well enough to go further into this subject at present, and will conclude with the following extract from a leading article in the *Times* of the 19th of August—"Fortunately for those who can afford it, unfortunately for the cause of science and for the public weal, it has always been possible to obtain good Potatoes at Covent Garden or of any ordinary greengrocer. If they are not to be got at home, they come in from abroad, and the households that pay, without scrutiny, a pound or two every week in the single item of vegetables are not the friends of inquiry and improvement. But the mass of consumers and of growers have been equally apathetic. The ordinary gardener has gone on from year to year planting the same sort in the same plot of ground, always selecting the smaller tubers as being good for nothing else. Seed Potatoes are the worst Potatoes of the crop, and though it is constantly affirmed that the size makes no difference, it must be admitted that the belief wants the justification of results. Upon the whole, there is no matter of equal importance on which there has been less inquiry, less experiment, and less application of intellect."—THE WRITER WHO FOLLOWED "W. B. W."

MUSHROOMS.

MATERIAL should be collected to form beds to afford a supply of Mushrooms by the time the outdoor beds are exhausted. There is no question as to droppings daily collected from horses kept on hard food, and spread out thinly under cover, being the best material for the purpose, continuing this until a sufficient quantity is collected, and then throwing it into a heap to induce fermentation. When that has taken place and before the materials are highly heated turn them over, finally placing them in the bed to a depth of 20 to 24 inches, well beating them down. A thermometer with the bulb 4 inches beneath the surface will show the temperature of the bed, the maximum being attained in about a week, when if it is not likely to exceed 90° the spawn may be inserted at once. It should be in pieces about 2 inches square, and placed 9 inches apart every way, only so deeply as to be covered with the material, beating the bed to render it firm after the spawn is inserted. In the course of a week or ten days cover it 2 or 3 inches deep with good turfy loam, which should be sufficiently moist to be easily beaten into a firm mass, making the surface smooth with the back of a spade. Over this a layer of coarse hay or soft litter about 6 inches thick may be placed, which will maintain uniformity of moisture and prevent the surface cracking; but it should only remain on until the Mushrooms begin to appear, when it must be removed and the soil kept constantly moist. The temperature should be kept equable at 55°, though with a house that is kept at 50° naturally no fire heat will be necessary, but it is essential that the latter

be the minimum to ensure a continuous supply of Mushrooms during the winter months. The time and trouble of collecting the material may be dispensed with where there is a sufficient accumulation in the dung yard in the course of a fortnight or three weeks to allow of the short material being shaken out, which may be formed into beds 18 to 24 inches deep, and when heated can be beaten down and otherwise treated as before advised. If the material shaken out be light about a sixth of turfy loam may be added before placing it in the bed.

FRUIT HOUSES.

Peaches and Nectarines.—The trees in the earliest-forced houses will soon be shedding their leaves, and as soon as those are all fallen the shoots may be loosened from the trellis to have it painted, and the woodwork of the house also, thorough cleanliness being of first importance in the forcing of fruits. When any renovation of the borders has to be done it should be attended to as soon as the leaves show indications of falling, and where new borders have to be formed the necessary material should be collected and stacked for future use. Peaches and Nectarines do best in rather strong loam, and if of a chalky or a calcareous nature all the better. The top 3 or 4 inches of grass or pasture land without the addition of manure is the most suitable. Soil deficient in calcareous matter may have a tenth of chalk or old mortar rubbish mixed with it, and light soil should have an admixture of about a sixth of clay. The border must be efficiently drained with about 9 inches of rubble, and have drains to carry off superfluous water, 24 to 30 inches depth of border being sufficient; and should be so arranged that the trees for forcing may be planted inside, allowing the roots to extend in outside as well as inside borders. For early forced Peaches and Nectarines planting should never be delayed longer than the end of September. As the fruit from the succession houses is cleared off thin out all shoots not required, so as to admit all the light and air possible to those left for the purpose of properly maturing the wood. Syringe the trees to keep red spider in check, and see that the inside borders do not lack water, admitting air freely, and in case of the wood not ripening well a gentle fire heat will be an advantage, air being admitted night and day.

Pines.—Suckers obtained from the summer fruiting plants will soon be ready to be repotted. Transfer the strongest to pots 10 and 11 inches in diameter according to the variety, affording the plants a position near the glass in a light airy house, keeping them gradually growing throughout the winter months, under which conditions they start into fruit readily about the following May or June, and afford a good supply of early autumn fruit. The remaining portion of the plants above referred to should be wintered in 7 or 8-inch pots, and placed in larger pots in spring. These, with suckers of Smooth-leaved Cayenne and Charlotte Rothschild started last March, will without much difficulty provide a successional supply of ripe fruit throughout the winter months, and be supplemented by Queens and other varieties which were started at the same time. At this period of the year it will be necessary to effect a re-arrangement of the plants which were started as suckers last autumn, many of the free-fruited varieties now having fruit swelling off; and these should be separated from the others, as plants not in that condition will by this time have completed their growth, and will more readily start into fruit at the required time by subjecting them to more liberal ventilation during the next six weeks when the temperature exceeds 80°, the temperature at the roots being kept at 75° to 80°. For plants that have been recently repotted 90° at the roots is suitable, but for plants well established a mean of 80° is best. When fruit is swelling off the atmosphere should be kept moderately moist, and a little air admitted at the top of the house early in the morning to dispel superfluous moisture before the sun's rays act powerfully on the fruit. Ripe fruit required to be kept should be moved to a shady house and have abundant ventilation. Shading should be dispensed with except for rootless suckers.

PLANT HOUSES.

STOVE.—Ixoras that have been employed for conservatory decoration must now be placed in warmer quarters; the rest they have had whilst in the cooler house will be sufficient for them. All the old flowers should be cut off, and if there be any mealy bug or scale give a good dressing with an insecticide. Clerodendrons, Bougainvilleas, and similar plants that have whilst flowering been placed in a cool

house must now be removed to a warmer situation, but not where they will receive so much heat as to excite growth, and should have a drier atmosphere to ripen the shoots, supplying water only to prevent flagging. *Medinilla magnifica* when in a moist high temperature grows freely, but does not flower well; but in plenty of light and not too much heat it flowers freely both from the current year's and the old growths. It should now be kept drier, ceasing to syringe it, and watering only to maintain the foliage in good condition. *Æschynanthuses* coming into flower must not be neglected with water, or the probability is the flowers will drop when showing.

Amaryllises.—The growth of many of these fine spring-flowering plants will be complete, and they should have a house with plenty of light and air, so as not only to thoroughly ripen the growth, but increase the size of the plants and induce free flowering; indeed they should be grown under conditions favourable to the solidification of the growth all through its formation—a matter of great importance; and instead of drying them off, as is often done, water should be given so as to keep the soil moist.

Achimenes and Gloxinias.—Plants that have nearly done flowering are often placed under shelves or in cool houses, where they are allowed to remain until the weather becomes cold, and are then removed to a warmer position; the consequence is the corms are very small and weakly. Instead of removing the plants from the light they should be kept close to the glass with the temperature necessary to grow them in, and have sufficient water to keep the soil moderately moist until the corms are matured and the tops have died down. If any varieties of Gloxinias are required to be increased, the matured leaves may be inserted round the sides of pots well drained, and filled with sandy loam or peat, with half an inch of sand on the surface, and being kept rather close and moderately moist they will form young plants. Scarce varieties may have the leaves laid flat on the surface of the pots, severing the midrib nearly through on the under side three or more times, placing a small stone on the top of the leaf over each cut.

Euphorbias and Poinsettias.—Plants that were moved some time ago from heat into cooler quarters must not be allowed to remain too long; or the roots will decay, and the plants will dwindle away when they should be starting into bloom. They should have a house or pit kept at 55° at night, with plenty of air and light. Poinsettias that have been planted outdoors or placed in cool pits must at once be moved indoors; and those planted out should be lifted with as little mutilation of the roots as possible, and potted in well-drained pots in a mixture of turfy loam and leaf soil, keeping them close, shaded, and moist until established. These plants cannot have too much light and air, the temperature being kept from falling below 55°.

Winter-flowering Plants.—The earliest batch of *Plumbago coccinea* *superba*, *Eranthemums*, *Thyrsacanthus rutilans*, *Centropogon Lucyanus*, &c., will by this time have filled the pots with roots, and should be supplied with liquid manure, and be kept near to the glass in a light house or pit, with a free circulation of air, so as to induce stout short-jointed growths, and with these well ripened a full complement of bloom may be expected, it being useless to expect well-developed flowers from puny plants. Winter-flowering Begonias should be potted without delay, and be grown in a light position.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Onions.—If those to stand the winter are not already sown the operation should no longer be delayed. Select open ground, which should be well manured and deeply dug, heavily trampled, and raked. Draw shallow drills about 10 inches apart, water them if at all dry, sowing the seed thinly a few hours later, trampling it in and raking over. The white Tripoli varieties, such as the Early Naples or Early White Italian, are the earliest and mildest in flavour, and the Brown Tripoli and Giant Rocca grow to a great size and are the best keepers. Assist the ripening of the spring-sown varieties by twisting down the tops of those that require it, and those with their tops dying should be pulled and laid on a dry base in the open to thoroughly ripen, and thereby improve their keeping qualities.

Cabbages.—Seed may yet be sown, as although the plants obtained will not be strong enough to put out this autumn they, if properly thinned, will stand the winter in the seed bed and may prove useful for planting the following spring. Prick out the seedlings obtained from early sowings, as strong sturdy plants will be found to succeed best. There is a prospect of the ground at present occupied by the spring-sown Onions being at liberty in good time to admit of Cabbages being planted on it, and will be found very suitable. Unless exceptionally hard digging is unnecessary; merely hoe the ground and rake off the rubbish, then draw drills about 3 inches deep, plant firmly with a trowel, and water in. The rows for the strong-growing sorts, such as Early Enfield, Early Heartwell Marrow, and The Battersea may be placed 2 feet apart and the plants 18 inches apart, provided large heads are required; but on good ground, as a rule, 1 foot apart in the rows will give the best returns. The smaller varieties may be planted 15 inches apart each way, or the rows 18 inches apart and the plants thicker in the rows.

Cauliflowers.—Seed should now be sown for the earliest crop next season. Select an open spot and sow thinly, in order to have strong plants for wintering in boxes and frames. The Early London and Dwarf Erfurt Mammoth are both suitable, giving the preference to the latter.

Spinach.—The present is a good time to make a sowing of either round or prickly Spinach to stand the winter. Select ground that was well manured for a previous crop of any kind, break it up thoroughly and deeply, make it tolerably firm, and sow thinly in drills 10 or 12 inches apart. Where this crop has previously failed on the level it is advisable to try a sowing on a raised south border.

Celery.—Some of the earliest is now being earthed up. Previously to the commencement of this operation it is a good plan to lightly cover the soil in the trench with a mixture of soot, lime, and a small quantity of salt, which watered in will act as a manure and also prove obnoxious to insect enemies. The earthing-up should be done gradually at intervals of a few days. First pull off all side growths, then tie up with matting a little above the hearts and earth nearly up to the ties, which should be then taken off, the operation to be repeated as the heart advances. Give the later plants abundance of moisture at the roots varied with liquid manure, and to prevent rapid evaporation and also their opening-out and consequent splitting of the stalks when tied up, work in about 2 inches of fine soil around them.

Keep all the side shoots closely rubbed off the stems of the Tomatoes, but do not denude the main stems of their foliage as yet. During hot dry weather they require plenty of moisture and rich food at the roots, or the fruit will be small. Thin out Endive, and transplant if more is required, and sow the black-seeded Cos Lettuce, Hicks' Hardy Cos, and any of the hardy Cabbage varieties of Lettuce to stand the winter. Insects and birds are more destructive to these than is the frost. Any vacant spots may be sown with Turnips, as they do not impoverish the ground and may prove serviceable.

GREENHOUSES AND FRAMES.

Stage Pelargoniums.—No time should be lost with regard to pruning the well-ripened plants of these. Cut back the young shoots to within three joints (two if they are weak) of their starting point this season, thinning out the old wood where crowded, and shortening-in where straggling, the aim being to obtain a neat head with a few strong shoots. Withhold water till they start afresh, and before they have made much progress shake the roots clear of the soil, shorten them back considerably, and repot in small pots. The pots must be clean and well drained, and employ soil consisting of two parts good loam to one of leaf soil, with a good addition of road grit or sand. Place the plants in a cold frame, keep them dry for a week, avoid shading, and ventilate freely. Cuttings may be inserted at pruning time, and may be treated similarly to the bedding Pelargoniums.

Calceolarias.—The present is a good time for sowing seed of the herbaceous section. Employ either 6-inch pots half filled with drainage or well-drained shallow pans. Over the drainage place moss or rough soil. Fill up with a mixture of three parts fine sandy loam to one of leaf soil, finishing off evenly and firmly. Over this dust some sand and water thoroughly through a fine rose, and allow it to stand say through the next night; then sprinkle over a little sand, and into

this press the seed with a small clean flower pot, and sprinkle over a little more sand. Place the pots or pans on a bed of ashes in a shady spot, the north side of a wall being suitable, and cover either with a handlight or a square of glass till the seedlings are up. No watering ought to be necessary till the seeds have germinated. Rather than water the surface soil either before or after the seedlings are up dip the pots or pans in chilled water till the soil is moist.

Cinerarias.—A little seed sown at the present time may furnish a few plants for late blooming, which if small may be useful. They may be sown at the same time and receive precisely the same treatment as advised for Calceolarias.

Propagating Bedding Pelargoniums.—Although the Pelargoniums are now really at their best, they in most instances will have to be propagated at once. The growth made, owing to the showery weather experienced, is of a sappy description—very unsuitable for cuttings, and for this reason propagating has been delayed. The late fine bright weather had a very beneficial effect upon them. Select as much as possible those growths that are really most floriferous, as they will both strike more readily and also make better plants than the succulent undergrowth. In many cases the tops may be cut back to a truss of bloom, which will maintain the display till other blooms have developed. Cut to a joint and trim off the lower leaves and bracts, and firmly fix in light sandy soil, being always careful that the base of the cutting touches the bottom of the hole made by the dibber. Shallow boxes are used where large quantities are grown and where there is plenty of house room for their reception; but in small gardens, where they have to be wintered either in frames or on shelves in greenhouses, 4-inch or 5-inch pots, each holding four or five plants, are the most convenient. They are also less liable to damp off when in pots whether large or small. Drain the pots well, and when filled with cuttings place them in a sunny spot where they can be kept dry, and do not water for at least a week. Commence with the choicer kinds, such as the bronze, silver, and golden-leaved varieties. Strong healthy cuttings of Verbenas dibbled in 5-inch pots, well drained, and filled with light sandy soil and watered in, will strike freely in a close frame or handlight, and will form stock plants for another season.

TRADE CATALOGUES RECEIVED.

Jas. Dobbie & Co. (late J. Dobbie), Rothesay, N.B.—*Catalogue of Vegetable and Flower Seeds.*

Webb & Son, Wordsley, Stourbridge.—*Illustrated Catalogue of Bulbs.*

Le Tall & Davis, 47, Exchange Street, Sheffield.—*Price List of Bulbs.*

Sutton & Sons, Reading.—*Illustrated Catalogue of Bulbs.*

Palm Leaves Scorched (*S. H.*).—The plant requires a more shaded position, and if all the leaves are like the one sent more water at the roots and in the atmosphere also. The leaf is very deficient in substance, and in just such a state as to be liable to injury by a few hours of bright sun. The root-action is defective, but having no data to guide us we cannot suggest what is the cause of this, and consequently are unable to suggest a remedy.

Strawberries, Weight per Acre (*A. B.*).—It is not easy to answer your question, but under ordinary field culture in rather light soil we should consider 1 lb. of fruit per square yard "a fair average crop in a fair average season." This is a little over 2 tons 3 cwt. per acre. Under superior cultivation by trenching and manuring Mr. Lovel of Weaverthorpe has, we believe, gathered 3 lbs. of fruit per square yard.

Potatoes, Weight per Acre (*Idem*).—Six to seven tons per acre is a good average crop under field culture in ordinary soil and seasons. Under very favourable circumstances we have often known yields of 10 tons per acre. The quantity of seed for planting an acre depends entirely on the size of the tubers and the distances they are planted. Some growers will plant an acre with 8 cwt. of small tubers, while others will use half a ton or more of larger sets.

"Green" Gooseberries (*Idem*).—Whitesmith and Crown Bob are popular varieties with growers for supplying the markets with green fruit early in the season. The following are also valuable for this purpose—Antagonist, Companion, Gunner, and Clayton.

Deodorising Sewage (*S. K. T.*).—You cannot adopt a simpler and better plan than to have a heap of freshly slaked lime near the cesspool, and when the contents are being emptied use the lime liberally as the work proceeds. This is the plan adopted in large towns, and when well carried out no cause for complaint arises.

Parsley-leaved Elder (*F. H. R.*).—The sprays sent are of the above Elder (*Sambucus nigra laciniata*), and if the tree has not been planted in the place in which it is growing it has probably sprung from a seed that has been carried by a bird from a fruiting specimen in some adjacent garden, perhaps from your Grace's own pleasure ground.

Vegetable Marrows not Setting (*J. W.*).—There may be a deficiency of pollen, and the flowers are not fertilised. If you apply the pollen from the staminate to the pistillate flowers, cut the tops off the exuberant growths and keep the plants well supplied with water, we think the fruit will set and swell freely. Artificial fertilisation is seldom needed when the staminate flowers are numerous, but when they are few in number such manipulative aid is often requisite. Are the growths of your plants thinly trained? Overcrowding would cause the evil of which you complain.

Heating Stove (*C. B.*).—To heat the proposed stove you will require four rows of 4-inch pipes along the front and at one end; you already have a flow and return at the other end, from which take the pipes for heating the stove, branching from near the front of the house, so that it will be possible to have the stove and vinery heated separately or together by fixing valves on both the flow and return pipes where they join the mains, as when the Vines in the house to the right of the stove are forced you will have too much heat in the stove, especially in summer. With the valves the temperature may be regulated as required. The additional piping is not great, so that the boiler will probably heat it satisfactorily.

Destroying Earwigs (*K. A. T.*).—We have not had experience of the effects of nicotine soap on earwigs and ants. It is worth trying, syringing the climbers at night as you propose, and if it does not kill the pests it will probably considerably check their attacks. Use it at a strength of 4 or 5 ozs. to the gallon of water.

Annuals for Spring Flowering (*Idem*).—Seed of *Saponaria calabrica*, *Silene pendula* and its variety *compacta*, which are amongst the most hardy and useful for spring bedding, should be sown at once. *Nemophilas*, *Larkspurs*, *Collinsias*, *Limnathes Douglasii*, *Lasthenia californica*, *Campanula pentagonia*, *Clarkias*, and other free-growing annuals are preferably sown from the 6th to the 10th of September in your district, as if the plants make too much growth before winter they are liable to be killed. Sow the seed thinly in drills a foot asunder, and immediately the plants can be handled thin them out to enable them to assume a sturdy habit of growth. The ground should be made firm, and a sharp look-out must be kept for slugs. The site of the seed beds should not be near old walls or crops that are likely to afford harbour to slugs and snails.

Men Required in Garden (*T. H.*).—Even when particulars are sent of the size and number of the glass structures, the arrangements of the garden, and nature of the soil, such questions can only be answered approximately. As you have stated your question it is quite unanswerable. You do not give the size of any of the forcing houses, vineries, or pits, but only mention a "large conservatory, 27 square feet." As this would only represent a house 6 feet long by 4½ wide it can scarcely be termed "large." If you will send us the accurate dimensions of all the houses and pits we will endeavour to answer your question.

Dionæa Muscipula Culture (*Idem*).—Anyone possessing a warm greenhouse may, with a little care, succeed in growing *Dionæa muscipula*. It is a native of Carolina, North America, where it grows in marshes or bogs. The soil best suited for it is sandy peat, with a little finely chopped sphagnum moss. After being put into well-drained small pots a slight covering of live moss should be laid on the surface. They should be then placed on a shelf in an ordinary greenhouse exposed to the full force of the sun. As they require a good deal of water a layer of moss should be placed on the shelf and the pots slightly plunged in it, the moss being kept moist, which is preferable to placing them in flats of water, as in this manner the soil is not so apt to sour. When the leaves commence decaying withhold the water, but never let them dry-up entirely.

Peas (*G. C.*).—It is impossible for anyone to identify Peas by merely seeing the pods, and your description of the plants does not aid us in the matter, for many Peas grow 6 to 8 feet high, bear heavily, and are of superior flavour. You do not even say whether the seed is wrinkled or not. The appearance of the Peas in a green state, and your description of them, leads us to suppose the variety is not distinct, but a form of the useful *Pea Ne Plus Ultra*. The pods sent are small in comparison with those of new Peas that are sent out now-a-days, but we do not doubt the variety is a very good one.

Fungus on Rose Trees (*General Davies*).—The leaves sent are not infested with red spider, but are seriously attacked with the black fungus. Syringe the trees with a strong solution of soft soap—5 or 6 ozs. of the soap being dissolved in a gallon of water, and apply it at a temperature of 120°. Nicotine soap of the same strength would answer equally well. Sponging the leaves with 2 ozs. of blue vitriol (sulphate of copper) dissolved in hot water, and added to 2 or 3 gallons of cold water, will also destroy the fungus. Possibly your Roses need more support, such as liquid manure; the fungus is generally the worst on Roses that have partially exhausted the soil, but there are exceptions to this rule.

The Cherry Plum (*F. H.*).—This is the name of the Plum of which you have sent fruit; it is also known as the Early Scarlet, Miser Plum, Myrobalan, and Virginian Cherry, and is described as follows in Dr. Hogg's "Fruit Manual." Fruit medium sized, cordate, somewhat flattened at the stalk, and terminated at the apex by a small nipple, which bears upon it the remnant of the style like a small bristle. Skin very thick and pale red, covered with small greyish white dots. Stalks three-quarters of an inch long, slender, and inserted in a small cavity. Flesh yellow, sweet, juicy, and subacid, adhering to the stone. It may be used in the dessert more as an ornamental variety than for its flavour, but it makes excellent tarts. Ripe in the beginning and middle of August. The young shoots are smooth, slender, and thickly set with buds. This is the *Prunus myrobalana* of Linnaeus. It is frequently grown in shrubberies and clumps as an ornamental tree, where in spring its profusion of white flowers render it an attractive object.

Forcing French Beans (*T. H. S.*).—The exuberance of the growth may arise either from the soil being too rich and light, the insufficiency of light, or an unsuitable variety being grown. We do not think your proposed mode of raising the plants would be any improvement on raising them in small pots and planting out. Allow them a little more room, make the soil somewhat firm, have them as near the glass as possible, and let the glass be washed clean, then by maintaining a right temperature and ventilating judiciously you ought to secure good crops. The flower you have enclosed is *Hypericum calycinum*, hardy species, which succeeds well under the shade of trees.

Plum Leaves Discoloured (*G. B. C. W.*).—There are no insects on the foliage to account for the glaucous appearance of the leaves, nor can we inform you of the cause of their present condition. You do not state whether the tree has grown freely or not, nor whether the soil is well drained. The trees, which

you state are growing healthily and bearing freely in brick rubble and sand, indicate that the soil in which the affected tree is planted is too rich and moist. You cannot err by lifting the tree in the autumn and placing the roots in fresh soil, to which has been added some rough gritty material, such as old lime rubbish, broken bricks, or roadside scrapings. If the tree is crowded with growth thin-out the shoots now, so that the sun and air can have access to those remaining to promote their maturation.

Vines in Pots (*Yorkshire*).—As you cannot keep the Vines during their resting period in a temperature of 50°, and as you have no cooler house for them, you must winter them out of doors. Drying the roots in the autumn and winter is a most injudicious mode of resting Vines. The roots should be in moist soil always, but never saturated. Retain the Vines under glass until the wood is hard, brown, and ripe, and the foliage shows signs of changing; then remove them to the open air, securing them to a wall or fence having a southern aspect. As soon as the foliage falls prune them, cutting off each side growth to a bold eye or bud as near the main stem as possible. Such a bud can generally be found about an inch from the base of each lateral; shorten also the leading cane, leaving from 1 to 3 feet as is most convenient for the size of your house. After pruning again, secure the canes to the wall, and pack leaves, litter, or ashes thickly round the pots and over the surface to exclude frost, which is liable to both break the pots and injure the roots. Place the pots on bricks to prevent worms entering them, and your Vines will be safe; or if the frost should be unusually intense they can be easily made so with a little covering. Well-ripened wood of the Vine, is, however, quite hardy. When the Vines commence growing in the spring see that the drainage is in good order, remove the surface soil, and dig out as much of the soil down the sides of the pots as possible, and add fresh loam mixed with a little bone dust and plenty of wood ashes, pressing the compost down firmly; or you may, if convenient, shift the Vines into larger pots. Vines in pots do not usually succeed nearly so well the second year as the first, though sometimes they afford useful bunches.

Names of Plants (*A. B. C.*).—1, Very insufficient for identification, but is apparently a portion of a Palm leaf, probably a species of *Phoenix*; 2, Resembles *Adiantum Capillus-Veneris*; 3, Cannot be named without flowers. (*J. Mark*).—*Mimulus cardinalis*. (*G. T. B.*).—*Hippophaë rhamnoides*, the Sea Buckthorn, (*W. H. Crossley*).—*Rhus Cotinus*, which is also known as the Venice Sumach. (*G. B. C.*).—1, *Goniophlebium subauriculatum*; 2, *Asplenium bulbiferum*; 2 and 3 were too withered to be identified. (*Lady King*).—The tree is *Acer campestre*. (*Inquirer*).—1, The plant growing through the Mediterranean Heath is *Sisyrinchium anceps*, a native of Bermuda, a small ornamental plant, frequent in gardens; it produces seed abundantly, and it has become naturalised in some parts of Britain; 2, *Lysimachia quadrifolia*, Four-leaved Loosestrife, a North American species; 3, *Erigeron purpureum*, Purple Erigeron; 4, *Epipactis palustris*, Marsh Helleborine, a handsome British Orchid, growing abundantly among the sand hills in Lancashire, but it is not confined to the seacoast, but is frequently found inland, as at Knutsford Bog in Cheshire, growing along with *Orchis latifolia*, *Gymnadenia conopsea*, and the Marsh Fern, *Lastrea thelypteris*. (*W. H. Myers*).—1, *Lythrum Salicaria*; 2, *Campanula muralis*. (*A Subscriber*).—We cannot identify the specimen without flowers. (*Plant*).—*Diplacus glutinosus*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CROSS-BREEDING OF SHEEP.

THIS subject has received more or less attention from agriculturists for a long period, but we do not find that cross-breeding was much attended to until the early part of the present century. During the eighteenth century we find that some sheep-breeders were extremely jealous of maintaining the purity of the principal breeds, such as long-wools, short-wools, black or white-faced sheep, horned or hornless races. A remarkable instance of this occurs in the history of the so-called New Leicester sheep, brought to great perfection by the perseverance of the celebrated Mr. Bakewell of Dishley. He commenced his career in 1760, and let his first ram for the season for 16s., whereas in the year 1786 he obtained three hundred guineas for one ram. To exhibit the decided temper of sheep-breeders at that time a club was formed called the Dishley Society, the object being to insure the pure breeding of Bakewell's type and style of Leicester sheep, for which purpose a code of rules and regulations were formed and made binding upon all its members to carry out certain conditions, all intended to maintain the purity of the Leicester breed. History or tradition, however, fails to supply us with particulars of the origin of many of our various breeds of sheep; but no doubt for many centuries after the time of the Romans in this country certain distinct breeds were perpetuated with but little improvement and little change.

In giving our opinions upon the policy of cross-breeding one thing must be borne in mind—that pure breeds or animals of

a certain fixed type and established character must be maintained, or our materials for crossing and improving certain varieties of sheep cannot be mingled with advantage. Whatever objects may be in view by those who cross-breed it is very desirable that they should assume some distinct form, for some farmers are in the habit of using crosses in their flocks, having no object in common. We will endeavour to define some of these objects. First we have those who mix the breeds with the view of improving only the sort which they have chosen as best adapted to the soil and climate in which they are reared; secondly, some think they can see their way to establish a new breed or type altogether; and thirdly, we frequently see sheep of mixed breeds, which are reared entirely with the view to making more profit by the produce of stock the result of a single cross. Now, we hold that the first two are not only of the greatest consequence, but also of the greatest difficulty practically, and requiring most judicious and careful management, and in either case within our knowledge only a few have succeeded in the accomplishment of their object. We propose to give the home farmer well-authenticated statements of the method pursued by those who have succeeded in effecting their object.

Let us take first for consideration the methods adopted by crossing or mixing the breeds of sheep for improving the character of sheep without any material alteration of type or style, taking first the long-woolled breeds. We must here remark the singular and decided advantage of using rams raised from stock so long maintained in purity like the Leicesters, as reared by Mr. Bakewell for so many years, and again by Mr. Valentine Barford of Foscote, near Towcester. Since the year 1810 the latter had bred entirely from his own flock up to about the year 1856, without any interchange of male or female from any other flock. We have heard him say "that his flock being bred from the nearest affinities, commonly called in-and-in breeding, had not experienced any of the ill effects ascribed to the practice." It is very well known that these pure-bred Leicesters have furnished the materials for improving the quality and wool of nearly every long-woolled breed where the rams have been judiciously used, including the Cotswolds, the Lincolns, the Cheviot, the Romney Marsh sheep, the Devonshire South Hams breed, and the long-woolled sheep of Ireland. All these have been much improved by the Leicester blood. In nearly every instance, however, the original size of the animals has been reduced, but the aptitude to fatten and the quality of the flesh has at the same time greatly increased, and with the further advantage of earlier maturity in the animals.

We must next refer to the South Down sheep, whose long line of descent can be traced from a period previous to William the Conqueror. It is without doubt one of the purest and unmixed breeds in the kingdom, as well as one of the most valuable. The uplands of Sussex is the native locality of the breed, and their first improvement was due to a Sussex man—Mr. Ellman of Glynde. He never exhibited his stock at any of the prize meetings, being intent only on being considered a careful breeder, to whom the farmers could resort with safety. Mr. Grantham of Lewes exhibited this breed, and for some years carried off the greatest number of prizes at the Smithfield cattle shows at Christmas. The exertions of another breeder soon after gained him great notoriety; we refer to Mr. Jonas Webb of Babraham, Cambridgeshire, who in a most remarkable manner proved himself by far the most successful breeder of South Downs, and whose system of breeding and selection increased the size of the animals without losing their quality. Since the late Jonas Webb's time the quality of the breed has been well maintained by the flocks of Lord Walsingham, the Duke of Richmond, and others; but we think they have lost both length and size. The effect of crossing with the short-woolled breeds has been marvellous, for the South Downs have been the means whereby various new types of sheep have been formed which have risen into celebrity within the past thirty or thirty-five years. Some of these now rank amongst our most useful sheep stock, such as the Shropshire, the Hampshire, and the Oxford Downs, each of which have within the last twenty years been admitted into the prize list of the Royal Agricultural Society of England. Previously the short-woolled sheep of nearly every breed were exhibited together, making it a very difficult task for the Judges, for on some occasions there have been sixty or seventy animals in the shearling ram class at the royal meetings. These singular competitions led to great good, for it induced the Society to encourage by their prizes the improvement and extension of these most valuable breeds of sheep. The South Down sheep are now to be found in nearly all parts of England, Scotland, and Ireland, and where the climate and soil is favourable they have not failed in giving satisfaction. They have to a great extent supplanted the native breed of black-faced horned sheep of Norfolk, also those of Cambridgeshire, Hampshire, Wiltshire,

Dorsetshire, and Berkshire, as our observations will fully explain when we enter upon that part of our subject relating to the method pursued by which the original breeds were crossed out.

The horned breeds of sheep, which are original and still existing in their ancient character, are interesting, if it were only for the fact of their holding their position whilst the great changes have been proceeding, and in which so many sorts of sheep have been lost altogether. The black-faced horned sheep have maintained their position against all comers in their native districts—the mountainous portions of Scotland and the northern counties of England, where they are always exposed to cutting winds, and being a hardy race they will live upon the poorest mountain herbage including the heather, and where no other breed could do so well. The small white-faced horned sheep are also noteworthy; they are natives of the Exmoor and Dartmoor districts, the Isle of Portland, some other western districts of England, and part of Wales, where they have held possession of the scanty pastures from time immemorial. The Exmoor breed in the hands of Mr. Merson and others have been greatly improved by selection only, and the sheep have been exhibited at Smithfield fat stock shows as miniature models of fat sheep. Lastly, there is a breed of horned sheep at once the most ancient, valuable, and purest of all the native breeds, namely the Dorset and Somerset horned stock, which have been always celebrated for yielding early lambs. When we first kept the Dorset breed in 1826 they were rather small, with a black speckled nose; these, however, have been merged in the large and splendid horned sheep called the Somerset with pink noses and most correct form, with excellent quality, good wool, and the carcase wide, long, and deep. They have also the character of being the best of mothers for rearing lambs, and will rear a greater number of twins than any other description of sheep.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The harvesting of grain and pulse crops and also the crops of second growth of Clover will engage both men and horses, for in nearly every district the cutting of corn, &c., with the reaping machine will be proceeding. There is, however, in various parts of the kingdom a considerable portion of the cereal crops so beaten down and damaged by storms that the scythe and fagging hook must be resorted to for harvest work, thus increasing the cost of cutting and tying. In some districts haying and harvesting will be going on simultaneously, thus making it both for men and horses an unusually busy period. The crops of Clover and grasses of every kind are very heavy and gross, and it has lately been found that sheep and cattle, the former especially, have become very relaxed whilst feeding thereon; but in those instances where Saintfoin, and particularly the giant variety, has been seeded with the Clovers, that it has through its aromatic and peculiar qualities had the effect of greatly diminishing or preventing diarrhoea. In the future we recommend the home farmer to substitute Saintfoin for the Rye grasses; this will not only prove a valuable alternation of seeding, but improve the quality and facilitate the making of hay wherever the farm is situated, so that a ready sale of vegetable produce can be effected. The growth of some of the late varieties of Peas is worth attention, for we have seen some extremely fine samples in the pod sold at a high price. The Potato crop is now attracting great attention in consequence of the extraordinary luxuriance of the haulm, especially in the Magnum Bonum and Scotch Champion varieties, and until within the past few days these have in most districts been found free from the disease, but now we have to report a most serious loss by the growing-out or sprouting of the tubers, and likewise an attack of the old disease. The sprouting of the tubers will prevent their sale; we therefore recommend the farmer to use them as food for the dairy cows, and mixed with bran it has been proved to furnish butter of better quality than any other food except grass in good condition. Bran is comparatively dear, but on various farms a portion of the last year's Wheat crop is still in store; and as the sale for it will be worse than ever, in the face of a crop of excellent grain of this year's growth it may be well to crush the old light Wheat, and employ it as food in connection with Potatoes for all animals in the stalls. Two feeds per day may be given to the dairy cows at milking time as a supplement to the grass in the pastures, and in lieu of the purchase of oil cake and other artificial feeding stuffs. The Potato haulm may be cut with the scythe and carted away for pigs in the farmyard and be trodden into manure, the Potatoes being lifted with the Potato plough and used as soon as lifted.

Hand Labour.—The men will be engaged in harvest work chiefly; but the second crops of Clover must be cut and stacked, for it will be all required, as so large a portion of the first cutting has been damaged or spoiled, and upon some farms there will be a scarcity of hay. We have on former occasions spoken of the plan where straw is plentiful of using it in layers in making a rick of Clover hay, because if the hay is carted rather green, it will heat and impart an aroma to the straw, and make it a valuable substitute for feeding when cut into chaff for horses, cows, and cattle in the boxes. Instead of laying the straw loose in the rick, we prefer to tie it into trusses, as it will then not only bear the weight of the Clover without slipping, but will

allow heat to escape from the rick more easily. The shepherd upon many farms will begin to feed his sheep on the early Turnips with a fold at night time; the lambs in particular, where they are to be forwarded for the butcher as tegs, may have a run at daytime upon Clover, Saintfoin, or fresh pasture, or parkland. All the late Turnips which are now fit to hoe must be attended to notwithstanding the heavy pressure of harvest work, and this may be greatly facilitated by driving the horsehoe across the drills, leaving the plants in bunches, which may be singled by hand or hoed out by men according to the labour at command. One thing, however, is certain, that after being horse-hoed between the drills, and then across them, it will prevent the roots from becoming stunted in their growth, and the hand-hoeing may be deferred in some instances until the busiest period is over. We will suppose that all stubble Turnips have been sown. The next move we recommend is sowing Trifolium, which cannot be done too early, because the young plant is the more likely to escape the ravages of the slugs. The winter Vetches, with a few winter Oats mixed, may next be sown; but these matters must not, or ought not, to interfere with the arrangements the home farmer may have previously made for the autumn cultivation by steam power of all land intended for Lent corn or root crops next spring. Upon many farms, owing to a succession of wet seasons, we find that large breadths of corn stubbles are very foul with Couch, Water Grass, Milk Thistles, &c., and much hand labour will be in most cases required to collect and burn, or cart away these weeds, leaving the land to be deeply ploughed after Wheat sowing is over.

THE HARVEST OF 1880.

THE *Agricultural Gazette* has published returns of the crops from the English counties, the results of which are tabulated as follows:—

CROP REPORTS FROM ENGLISH COUNTIES, 1880.

Reports.	Wheat.	Barley.	Oats.	Beans.	Peas.
Over average....	18	62	41	35	26
Average.....	81	88	105	67	69
Under average..	65	10	17	16	22
	164	160	163	118	117

The per-centage character of the returns will be seen in the following table, which may be compared with those of the previous years given below:—

PER-CENTAGE REPORTS OF 1880.

Reports.	Wheat.	Barley.	Oats.	Beans.	Peas.
Over average....	11	39	25	30	22
Average.....	59	55	64	67	59
Under average..	30	6	11	13	19
	100	100	100	100	100

On the whole, we must believe that Wheat is considerably under a good average. Barley, Oats, Beans, and Peas are, upon the whole, above an average. The Potato crop, which has been so great, is very far from satisfactory, owing to the very great prevalence of the rot. Root crops, except Mangold Wurtzels, are unusually good, and the later cuts of hay have been admirably secured. How much worse last year's report was than this is better recalled by memory than it is represented by figures. The following tables, however, will be examined with interest, for the contrasts which most of them present with that which represents the crop of 1880:—

PER-CENTAGE RETURNS OF HARVEST, 1879.

1879.	Wheat.	Barley.	Oats.	Beans.	Peas.
Over average....	1	4	20	4½	4
Average.....	24	35	57	29½	97
Under average..	75	61	23	65	66
Total	100	100	100	100	100

1878.	Wheat.	Barley.	Oats.	Beans.	Peas.
Over average....	21	11	22	7	6
Average.....	58	43	50	63	55
Under average..	18	43	28	30	39
Total	100	100	100	100	100

1877.	Wheat.	Barley.	Oats.	Beans.	Peas.
Over average....	3½	10	23	12	8
Average.....	24½	50	49	69	61
Under average..	71½	40	28	19	31
Total	100	100	100	100	100

The *Mark Lane Express* has also published returns, which are substantially the same as the foregoing, and remarks—"If the estimates now framed should turn out to have been well founded, the produce of 1880 will be largely in excess of the extremely meagre yield of 1879. The Wheat crop is below average, Barley is above, and Oats are also a little above an ordinary yield. Beans may be set down as a little above average, and Peas at a little below. There is scarcely a county in which mildew and blight

are not complained of as affecting the Wheat crop, which seems to be the worst corn crop of the year, as Barley is the best. Many of the reports complain that there is an unusually large proportion of shrivelled grain in the Wheats, and that the Barley is small in the grain and discoloured by the wet weather of July. Where the crops have stood well, however, the quality of both Wheat and Barley is good."

BUTTER AT THE CLONMEL SHOW.

THE report of Canon Bagot and Mr. Robertson on continental dairying appears to have already proved of great advantage in Ireland, as may be gathered from the following "judges' report" of the butter at the Show in question. The suggestions embodied in the report are of much more than local value:—"It is a great pleasure to be able to report most favourably of the butter exhibits this year, showing, as they do, a marked improvement in nearly every point that would tend to raise the character, and therefore enhance the price to be obtained for the article by the farmers. The variety and excellence of the exhibits made it a most delicate and difficult task to sift those out for prizes which by their superior excellence deserved such recognition; and we would like to add, for the encouragement of those who were not successful in obtaining prizes, that in a show in which almost perfection in colour, taste, and body had been reached by so many, it was no discredit not to be mentioned, as the slightest deviation from the highest standard of excellence in this Show meant certain defeat. It was noticeable and worthy of remark that there was not a single case of the heavy salting which has been a great drawback in times past to Irish butters when placed in comparison with the milder, and therefore more palatable, article produced and put on the English market by the farmers of Holland, Denmark, and France. We found that great care and attention had also been bestowed on the packages, and considering how important it is that an article like butter should be turned out of hand in a firkin clean, handy, and not unattractive to the eye of the purchaser, we think it well to place on record the very favourable opinion we formed on this important point. In fact, as regards the cooper's art, we agreed that in size, handiness, and workmanship, we might almost say symmetry of proportion, the packages and packing left little to be desired. In conclusion, we feel that if the producers of butter in this country, which is one of the finest butter-producing countries in the world, will only take the butter exhibited at this show as their standard of excellence, and follow it up and keep up such merit in production, they will have nothing to fear from foreign competition on putting it on the English markets. We would almost venture to predict that after they have overcome any slight prejudice there may be existing from hygone neglect, they will catch up and surpass any foreign producers, no matter whence they hail, and bear off the laurels due to the best producer—viz., the highest market price for his production."

THE POULTRY CLUB.

A COMMITTEE MEETING of the Poultry Club was held on the 13th at the Charing Cross Hotel; present, Messrs. H. R. Dugmore (Chairman), T. C. Burnell, S. Lucas, Rev. J. D. Peake, and O. E. Cresswell (Hon. Sec.)

A dispute between Mr. J. Turner and Mr. J. W. Ludlow concerning a private sale of a Cochin hen at the last Crystal Palace Show had been submitted to the Club, both binding themselves to abide by the Club's decision. An elaborate summary of the case was drawn up by Mr. Dugmore, and submitted beforehand to both parties interested, to aid the Committee in considering it. The following decision was given:—"The Committee of the Poultry Club decide, that taking into consideration Rule 3 of the Crystal Palace schedule according to which 'sales can be effected only through the Secretary,' it cannot recognise as valid a sale effected in any other way during the show. The Committee therefore decide that Mr. Ludlow's claim cannot be maintained."

The question of a new standard of excellence for the judging of some breeds of poultry was then discussed at the request of Mr. T. W. Anns and other members of the Club. The subject being a very wide one, and interesting to many fanciers not members of the Club, it was decided to reserve it for discussion at the General Meeting of the Club to be held at the time of the Crystal Palace Show.

The Honorary Secretary reported that he had received no answer to letters addressed to the Secretary of the late Kingston Show, from whom he had asked an explanation as to the deductions of an entry fee from the prize money of Mr. P. Haines, who had a receipt for his prepayment of the fee.

Much other business was transacted by the Committee, and the

Honorary Secretary announced that he felt himself obliged to resign his office at the end of the year. Lest there should be any misconception, he wished it to be understood that his sole reason for this step was that he now found the work of the Club beyond his powers. He took this early opportunity of announcing this intention, to give the Club plenty of time to consider whether any change in the office of Secretary for the future might be desirable.

GREEN FOOD FOR FOWLS.

IN good grass runs where the turf has been prepared from properly selected grasses and herb seeds, it is seldom necessary, unless in very hot weather, to supply fowls with any other green food besides what they are able to pick up there; but all fowls in confinement, or in such runs as afford little or no supply of green food, should have it given to them in abundance at the present time, and less or more throughout the whole year, but more particularly when moulting and in hot weather. Some fowls are very fond of green food of any description, and others will hardly eat it in any form. It depends very much on how they have been brought up. Chickens reared and allowed to run at large for a considerable time in a field, are frequently a long time before they will even deign to look at green food when thrown in to them in a confined run, and they have sometimes held out so long in this way that we have been obliged to chop up refuse vegetables small and mix them with the meal. This plan of giving green food is a very good one, and may be practised with all fowls and under all circumstances. Chickens, however, which have been reared in confinement and under mothers which were fond of picking at anything green, seem to take to green food naturally, and with such there is no trouble, as they will eat freely of what is placed before them. When green food is scarce, less is used when it is chopped up and mixed with the other food than when thrown down in the rough.

Another good way is to suspend it with a piece of cord about a foot from the ground, or just high enough for the fowls to reach it. They pick at this in a very cheerful way, and besides adding so much to their health, it affords them both amusement and exercise. No day should pass without fowls having some green food or other, and when they can supply themselves it is astonishing what a quantity they will sometimes eat. At certain seasons we have seen some of our birds prefer green food to all other, and they appear to live on little else. When green food is withheld from fowls the feathers frequently assume a dry withered appearance, which may relapse into something worse, and they seem to be particularly fond of eating each other's feathers, and this in the case of show fowls is a great evil, especially with crested birds, such as Sultans, Polands, Houdans, &c., as a ragged top-knot is a serious disfigurement.

In summer there are few instances where abundance of green food cannot be had of some sort or other, such as Cabbage, Cauliflower, Turnips, Beet, Lettuce, young Onions, and other crops which may be going to waste. But where green food is grown purposely for the fowls we would only grow Lettuce and Endive. These they eat most greedily, and they thrive better on them than anything we have tried, and we have tried all kinds of green food. The Endive we prefer most of the two, and so do the fowls, as it is very cooling and, being so bitter, is a fine tonic. Supposing any fowl not to be taking its food freely, if the leaves of the Endive are chopped-up and mixed with the other food, the difference in its appetite will soon be apparent. Plenty of green food acts more as a preventive and cure of disease amongst fowls than nine-tenths of the articles which are sent out as medicine. In winter or during severe weather it is often a difficult matter with many to secure a supply of green food, and then variety must not be much thought about. Cabbage, Brussels Sprouts, or Savoy leaves will do, and failing such as these, Turnip and Mangold Wurtzel roots are much better than nothing. Potato parings may also be included in the same category, and they are plentiful enough all the year round in most places.—J. MUIR.

VARIETIES.

THE monthly Committee meeting of the British Bee-keepers' Association was held at 105, Jermyn Street, on Wednesday, August 18th. The accounts were presented and past. It was arranged that the "Handbook for Cottagers" should be supplied in quantity at a reduction. One hundred 40s., 250 or upwards 35s. per hundred. The diagrams 5s. per set to those taking not less than five sets. The other business was principally of a routine character.

— AGRICULTURAL RETURNS.—According to the report for the

current year issued by the Board of Trade we find that the extent of land under Wheat is 2,909,148 acres, Barley 2,467,831, Oats 2,796,905, Potatoes 550,931, and Hops 66,737. Compared with the return for 1879 these statistics show an increase in the acreage of land under Wheat to the extent of 18,904 acres, Oats 14,287, and Potatoes 9587; and a decrease in the case of Barley of 199,345 acres, and in Hops of 934 acres. The total number of live stock is stated as—cattle 5,912,046, sheep 17,187,816, lambs 9,433,908, and pigs 2,000,722, showing a decrease in sheep and lambs of 1,535,357, pigs 90,837, and an increase of 55,690 cattle.

— WE have received the July number of the "Canadian Poultry Review," published at Strathroy, Ontario. The Pigeon fancy seems to progress in Canada, indeed in the said number an article by "C." on Fantails is copied *in extenso* from our columns.

— WE are requested to announce that one of the treasurerships of the Poultry Club having become vacant, Mr. A. Darby has been nominated for the office by Mr. O. E. Creswell and seconded by Mr. T. C. Burnell. Members of the Club who wish to nominate any candidate for the office are requested at once to send their nominations to the Hon. Sec.

— WE have before us the schedule of the Birkenhead Poultry Show, to be held on Sept. 8th and 9th. There are thirty-one classes for poultry and seventeen for Pigeons, with good prizes and moderate entry fees. The Staffordshire Society will this year hold its Show at Stoke-on-Trent on September 22nd and 23rd. The schedule seems much the same as in former years.

— HARVEST PROGRESS.—The highly favourable weather that has prevailed during the past fortnight has been of incalculable benefit in expediting harvest operations. In the south many fields are cleared, and the grain in not a few instances is so hard and dry as to be in good condition for grinding. In the midlands cutting is general, but the crops are so flattened and twisted that as a rule one-third more time is occupied in reaping than if the machines could work in the usual manner. Cutting has also commenced in the north, and three weeks of similarly fine weather as we have recently enjoyed would enable the bulk of the English harvest to be secured. The barometer, however, is now falling with a much-clouded sky, and rain may possibly follow before the end of the week; if it does it is much to be hoped it will only be in the form of a passing shower. Harvest work, says the *Farmers' Gazette*, is now going on in Ireland, and prospects are very much improved. The stalks of the Potato crop are beginning to show symptoms of decay, but there does not appear to be disease to any serious extent. The extraordinary luxuriance of the Champion Potato has been everywhere remarked. The hay crop is not heavy, at the same time the very moderate prices at which it can be purchased show that a scarcity is not anticipated.

— MESSRS. READ AND PELL'S REPORT ON AMERICAN FARMING. —Although this report is not yet issued to the public, a few copies have been supplied to the members of the Commission. The report consists of sixteen pages, and a number of statistics and facts which support or explain the conclusions Mr. Clare S. Read and Mr. Albert Pell, M.P., have formed are given in an appendix. With regard to the importations of live stock, the report states that whenever America can show a clean bill of health, and live imports are again introduced, a considerable trade in store stock will probably be developed. The largest portion of the report deals with the subject of Wheat cultivation. The Commissioners, on this subject, state that the yield of Wheat over a long series of years in the States appears to have just exceeded twelve bushels per acre. For the year 1879 the return of the yield is 18.1 bushels per acre. With a yield of twelve bushels the Western farmer could deliver from his waggon at the depôt without loss at the 3s. 6d. a bushel. In all parts of the report is noticed the aptitude and readiness throughout the United States with which the best machinery is obtained by the farmer, and it is pointed out that good machinery and improved implements are much more common on American than on English farms. The tools are lighter, better shaped and better made. "It may be true," we are told, "that a good workman never finds fault with his tools," but it

is truer still that a Yankee labourer is too sensible ever to work with a bad one.

— THE FUTURE OF AGRICULTURE.—Professor Wrightson made the following remarks on this subject in a recent lecture:—The true future of farming points in the direction of an enlightened tenantry exercising their vocation with freedom. We have a good climate and a grateful soil, but who ever commanded us to employ it solely in the cultivation of about half a dozen crops? We must gradually break through this tradition, and be ready to grow crops which will continue to be profitable. Farming will tend to approximate towards market gardening, and the rage for large farms will be found to diminish as a larger capital is found necessary to stock an acre of land. The tendency may be gradual, but it nevertheless exists, and we must be ready to accommodate ourselves to the necessities of inevitable changes. We must consider closely the directions in which we are likely to meet with the most severe competition. Wheat, and corn in general, is not likely to fetch high prices any more. Beef is likely to keep to a lower range than heretofore, and mutton will to some extent sympathise with beef. Milk, poultry, green fodder, Turnips, and soft fruits are, on the other hand, likely to maintain their value, because of their bulk and weight in proportion to their value.

THIRD ANNUAL SHOW OF THE HERTFORDSHIRE BEE-KEEPERS' ASSOCIATION.

At the annual Meeting of the above Association, held a few months since, the Rev. Herbert R. Peel suggested that in connection with the Show, which had at that time been arranged to be held at St. Albans, there might take place an exhibition of flowers, fruits, and vegetables. The encouraging result of this suggestion will be found chronicled in another column, here we have to do with bees and their surroundings. One of the highest feats of generalship is to create an army, and in this the worthy Secretary seems to have been successful, since the member roll of the Herts Association is stronger than that of any county association in the kingdom, and, as might have been expected, the Show was an admirable one, the collection of honey especially being, quality and quantity considered, equal to if not better than any we have yet seen. The Judges in the open classes were the Rev. Canon Kewley, Baldock, and the Rev. F. J. Wilcox, Frithsden; and of the county classes, T. W. Cowan, Esq., Horsham, and the Rev. J. S. Sisson, Edington Rectory, North Walsham. The hive classes call for no special remark after the digest of the exhibits at South Kensington.

For the best exhibition of comb honey in sections, each not more than 2 lbs. in weight, packed in the most attractive and portable form for sale. Although this class was confined to the county the display was splendid. Mr. S. Thorne took first with fifty-three large sections of his well-known quality. We hear that of the immense bulk of honey he had at South Kensington only one section remained unsold at the close of the Exhibition, so that these sections and those of his to which we come presently are another brewing altogether. This is all done with fifteen hives, and speaks well for the district, the bee-keeper, and the profits of bee-keeping. Mr. E. Bacon made a good second, and Mr. Frederick Smith third; Mr. Gulston being highly commended with twenty-seven large sections carefully decorated. No bad exhibit appeared. For the best five sections of comb honey, each weighing not more than 2 lbs. Here quality was the test, and here it was found. The sections were really artistic, flat, and faultless as slabs of alabaster. Mr. Thorne took first, the Rev. Herbert Peel second, Miss Gayton third, and Dr. Smith commended. For the best exhibition of honey in supers of any other kind than section boxes, Rev. — Jenkyns first and Rev. E. Bartrum second with three fine Stewartons; Col. Smyth took both third and fourth places. For the best exhibition of pure extracted honey in small glass jars, not to exceed 2 lbs. each, each entry to consist of not less than five jars, the competitors were sixteen in number, and the quality of the honey in many cases superb. Of the winning lots it is hardly possible to speak too highly. Clear as crystal, good in body, delicate on the palate, nothing seems to be left for improvement. The first and second quite correctly fell to Dr. Smith and Miss Gayton, and were, we understand, extracted from combs of the swarms of the year, and in which brood had not been raised; no breakdown, however, occurred. Comb honey, to be exhibited by *bona fide* cottagers. Here quality was not equal to that of which we have already spoken, but yet great advances have been clearly made. No first prize was awarded; second T. Hudson, Croxley Green.

The beeswax was shown in plain slabs. First Miss Gayton, second Mr. Thorne, third Mr. Clapp. The Rev. H. R. Peel offered a special prize for an exhibition of flowers suitable for the pasturage of bees, which fell to Mr. Gibbs of St. Albans. In the open classes for honey Mr. S. Thorne once more successfully battled against all comers. Mr. Walton's extractor received second, no first being awarded, on the ground, we understand, that as the cage is partly wood it renders the

honey sour. We had thought honey could only be rendered sour by fermentation. Perhaps someone possessing honey made sour by extraction will give us a little information.

The driving competition and subsequent manipulation were as usual sources of much attraction, and no doubt edification also in matters apicultural. In conclusion, it is clear that we may now regard as a thing of the past that dirty material contaminated with pollen and fouled by the juices of bee grubs, perhaps some days dead, and flavoured with sulphurous acid, which, as the latter is antiseptic, had for this mixture its advantages. Even this we once called honey, but now the word means an article of diet delicate in flavour, pleasing to the eye, sustaining to the system, and having about it no suspicion of any sophistication which could turn the most delicate or fastidious.

COMB FOUNDATION.

YOUR correspondent, Mr. George Procter, in his last communication on page 177 uses my name in a connection which I think he would hardly upon reflection regard as justified. He says, "Now Mr. Cheshire and Mr. Raitt can answer for themselves why they have endeavoured to strengthen foundation, but it strikes me that the public craving for novelties on one hand and the desire on the other for some material so prepared as to defy careless handling may have some part in the matter." If Mr. Procter thinks that a desire to satisfy a public craving for novelty has been the object sought in the devotion of very much time and the spending of a good deal of money in solving problems in connection with apiculture during several years, I can assure him he is totally mistaken. But for this remark I should not again have alluded to the sagging of foundation. Having solved the problem and communicated the method, my public work in relation to it is ended.

Mr. Procter's first letter a little puzzled me, but his second has brought its solution. He will, I hope, pardon my saying that a veil of such density as to allow brood to be mistaken for honey would account for much. I assert, without fear of contradiction, that machine-made foundation invariably stretches so little indeed in some cases that practically it is perfect, but so much in others as to spoil it utterly. I have a piece of Mr. Raitt's foundation now, 3 inches of which has stretched to very nearly 4 inches. Everybody of experience knows that if one side of a sheet be worked out before the other is attacked, that the corners if left to themselves retreat from the worked side, because that side, and that side only, has increased in size. Mr. Root, upon whose machine Mr. Raitt's foundation is made, surely knows somewhat of this question, and in the last month of "Gleanings" he speaks thus in referring to my wires:—"Mr. Cheshire, your experiments are most valuable, and the united world of bee-keepers owes you its thanks." Nothing can more surely damage the reputation of an article than claiming for it more than its fair due. Mr. Raitt's foundation is most excellent in quality, but in swarms in warm weather it will stretch, and often be utterly spoiled if used in full sheets unless assisted. The thicker the foundation is made the better it will stand, but this means waste if sagging can be prevented by other means less costly than a double allowance of wax. The thinner we can use foundation the better, because the more economical if we can get perfect combs, and at the same time save the bees almost entirely for wax secretion. But my wires have other advantages than those I have hitherto claimed for them. They fix the comb very quickly, secure perfect straightness, and prevent drooping; but in addition—as Mr. Cowan has pointed out to me, for it did not occur to me before his suggestion—they permit the use of thin foundation in hives and the joining together of pieces to make up a sheet, and this advantage lies happily altogether outside the contention of Mr. Procter's letter. His method of fixing his sheets I regard as unnecessarily troublesome, and quite out of the question in a large apiary. His reference to "boiling wax" for fixing is undoubtedly an oversight. Boiling wax is necessarily carbonised, and bees will not touch it, besides which it would simply melt instead of fixing the foundation. Wax at the temperature of boiling water must be meant, and this is essential; using wax only a little over its melting point, 150°, is generally the cause of breaks down, about which, as Mr. Procter rightly supposes, I know nothing experimentally. Mr. Hooker's method is much less trouble and quite as safe as the one Mr. Procter gives. He simply provides a saw-cut through the top bar; he springs the cut open with a large nail, holds it open with a simple tool somewhat like a big bell-hanging clip, withdraws his nail, and inserts the edge of the sheet. The removal of the tool grips the wax by the elasticity of the wood, and the thing is done. Wax may be run in if thought necessary. I simply use a board fitting loosely inside the frame, and of such a thickness as to hold the sheet in the correct position. On the back of this board are two stiffening strips extending beyond its edges, and

upon these the side of the top and bottom bars rest when it is in use. The sheet is laid on the board, which is held in the hand while the smelter runs in wax between its top edge and the top bar. I argue that it is an error to wax on both sides. On the other side the sheet is perfect to its very limit, and the bees build out the cells at once. Wax on both sides is often the cause of the comb being left unfinished at the top bar and afterwards perhaps dropping, though I believe this never happens unless rough handling has favoured the misfortune.

A new method of making foundation is springing up, which will bring a competitor to machine-made foundation into the market. I believe I may lay claim to being the introducer of wet plaster of Paris as a substance upon which molten wax could be formed in sheet. It is singular that this new apparatus is in form exactly like three or four made some years back, but with which I practically failed because I did not use my machine in the best manner. It is contrived thus: Two frames of wood, like slate frames somewhat, are hinged together. A sheet of foundation stands between them when they are shut, while upon each side of the foundation with due precaution plaster is filled into the frames. When this is fully set the frames are opened and the sheet removed. I operated thus: With a paint brush melted wax was coated on to one of the slabs of wet plaster and then the frames were shut together, but the wax set too quickly for me to get a good impression on the upper side. Our American cousins, however, have succeeded. They dip one frame while it is held in a horizontal position into melted wax, and then sharply shut the two together; and foundation having capital finish and an unpolished surface, so that it is very quickly worked out in the hive, is in a moment produced. Mr. Abbott, jun., showed me some he had made thus a few days since, and it seemed to be all that could be desired.—F. R. CHESHIRE.

BEES ON DARTMOOR.

I HAVE just returned home after a month's absence on the high grounds of Dartmoor, close to the border land where cultivation merges into the waste—the very *beau idéal* home of the bee. But I am sorry to say that among miles of Bell Heather and Ling in full blossom, across which we tramped day after day in the most perfect weather, neither ear nor eye were gladdened by the sight or sound of a single honey bee. Here and there we came across a hive or two where there ought to have been hundreds. The general cry was they had perished pretty nearly out of the land. The white Clover was still in full bloom on the 20th, and may have been preferred as yet to the Ling by those bees which have survived the winter, but still one expects to see the latter covered with bees by this time.

An old woman who had managed to save two stocks described in triumph what she thought was the secret of her success. For the two last severe winters she had simply plastered up every crevice, entrance and all, and not allowed a single bee to move abroad from just before Christmas to the end of March. She gave as the reason which induced her to try this mode of wintering that she found so many bees die in the snow, and blown away never to return by the cold winds of the early spring, that she resolved they should not budge at all. She said they were very weak but in good health when she liberated them, and although one of the hives had barely a teacupful of bees, by dint of feeding she had to encourage them, that they had swarmed twice each stock.

As to the march of improvement in bee-keeping there were no signs of such a thing. Small hives, which appeared smaller than usual were alone to be seen, and all the ancient slovenliness of bygone generations.—B. & W.

OUR LETTER BOX.

Ducks where Water is Deficient (*Mary*).—Rouen Ducks are, we believe, the best to suit you. Aylesburys are preferable if you have hens under which to put the eggs, as they are non-sitters, as they lay very many eggs, and fatten easily. Rouen and Aylesbury are the desirable breeds on account of their size.

Chickens Drooping (*B. C. D.*).—Remove your chickens to fresh ground, provide them with heaps of dust or road grit, and mix a little black sulphur with it. Feed them for a short time on stimulating food till they get over their troublesome time. Growing the crown and tail feathers are the "children's diseases" of chickens.

Feeding Chickens (*Tyro*).—For the first fortnight chickens are best kept upon alternate feedings of Indian meal, bread crumbs, and eggs boiled hard, chopped fine, and mixed with a little crushed hempseed. The Indian meal should be only so far moistened as still to remain crumbly. After the first fortnight, and until large enough to feed with the older fowls, give them daily in addition, a feed or two of either bruised Wheat or bruised grits. From the very first days of their life continue, without fail, to give them daily fresh green food. Cabbage and Lettuce leaves, and mowings of grass are best. Remember above all things that a little food given often—every two hours is not too frequently—is the chief rule for chicken-rearing.

Matching Game Bantams for Exhibition (*B. T.*).—A prize is awarded in Game Bantams, as with any other fowls, to the most meritorious pen. Matching is essential, and it would of course be sought by an exhibitor; but the fact of all three birds having a doubtful merit, or a positive defect, would not be lessened in its consequences by their all having it. We prefer a red earlobe in a Game fowl.

Tame Doves (*A. R.*).—The number of times that tame Doves breed in the year entirely depends on the way in which they are kept. If they live a tolerably natural life—i.e. if they are kept in an aviary in the open air, in which they do best, with of course proper protection from wet and cold winds, they will probably go to nest in March and continue to breed till the end of August, rearing about four pairs. If, however, they are kept in a cage in warm rooms they will continue laying all the year round with the exception of a short intermission during the moult. They will, however, probably rear fewer young in this way, as many will die, and some eggs prove infertile. Their food should be maize, wheat, and millet.

Books on Bees (*New Subscriber*).—Our mammal, "Bee-keeping for the Many," published at this office, price 4d., post free 4½d., contains useful instruction and concise information for young apiarists. Larger and good works are "Neighbours' Apiary," 5s., published by Kent & Co.; Cheshire's "Practical Bee-keeper," 2s. 6d., 170, Strand; and Pettigrew's "Handy Book on Bees," 3s. 6d., Blackwood & Sons. These works give sound information on the various modes of bee-keeping.

Langstroth Hives (*A Ten-years Subscriber*).—We do not possess Langstroth's hive, but believe the principle is the same as in the case of all other bar-framed hives. You cannot have a better hive than Mr. Cheshire's. By Italian bar hives we presume you mean hives for Italian bees. These bees are not imported into this country in Italian hives. Perhaps some of our correspondents who know Langstroth's hive by experience will kindly say if it is in principle different from our English bar-framed hives, and if they know anything of Italian bar hives.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

15th.—Cloudy and rather dull all day, with the exception of a little sunshine about 3 P.M.
 16th.—Cloudy and cool; not a glimpse of sunshine all day.
 17th.—Cloudy till about 11 A.M.; afterwards fine and bright.
 18th.—Dull cloudy day, with a few glimpses of sunshine at long intervals.
 19th.—Dull and cloudy till about 10.30 A.M.; remainder of day fine, bright, and pleasant.
 20th.—On the whole rather dull and cloudy, though there was a good deal of sunshine in afternoon.
 21st.—Rather cloudy early; fine and bright after 10 A.M.
 A fine week, but with a good deal of cloud and persistent N.E. winds. Temperature lower than that of the preceding week.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 25.

THERE is still a large supply of Grapes arriving from the Channel Islands, but that of home-grown fruit is very limited. Large quantities of Plums have arrived within the last few days, realising moderate prices.

MORE ABOUT POTATOES.

I SHOULD apologise, Messrs. Editors, for asking you to allow me to have my say also on the above subject did I not know that everyone who has the means of growing a few Potatoes has a lurking fondness for a chat about that most seductive and interesting vegetable. Few there are who have not some pet theory of their own about its culture, or some nostrum which ensures an abundant crop and freedom from disease. Almost every cottager one meets will, if you give him the chance, propound some deep theory about "taties," and give you his "pinion" as to the cause of the disease and his way of defeating the enemy.

One of the mysteries connected with this cherished tuber is the power it has of affecting everyone who talks about it with the idea that he knows more about its ways and doings than any other living being. Do I not now begin to feel its subtle power working in me? For whereas I started with the thought, that although I had been a student in the Potato school for many years, my education was as far from complete as ever; now I begin to fancy that I do know something after all. At all events I think I have proved the fallacy of many professedly infallible rules laid down from time to time by the would-be instructors in the art of Potato growing.

A few weeks since I saw it propounded in this Journal by "W. B. W.," that the way to obtain good crops and to avoid the disease is to select for seed the largest and best-shaped tubers only. I beg to submit that this is fallacy No. 1.

Some years ago I was in the habit of regularly exhibiting Potatoes, and had the gratification of winning many first prizes at various shows. Thinking to continue my successes with more certainty and greater ease, I used at first to keep all my prize Potatoes for seed, adding to their number any others that I was able to select from my stock of equal size and merit. These were planted with extra care at double the usual distance, and I expected grand results. I can only say that in every case I was disappointed. The produce was generally inferior to that obtained from my medium-sized seed, and quite as liable to disease. The supposition that the largest Potatoes have eyes of a better constitution than smaller tubers is, I believe, also a fallacy. No one who has grown Potatoes long can have failed to observe, that in years when disease is rife it is nearly always the largest tubers that are first affected. Last year, an unusually bad one, I dug about half an acre of Snowflake in which every large Potato was diseased. Only a

small proportion of the crop, and that consisting entirely of small and middle-sized Potatoes, escaped. Many a time I have had the rows overhauled to obtain exhibition specimens, and in bad seasons have been disgusted at finding all the finest touched with the abominable disease. My deduction, therefore, is quite the reverse of that of "W. B. W." I find that size and weakness of constitution as a rule go together, and my advice is, Send your large Potatoes to market or eat them. Do not waste valuable food by putting it into the ground to rot, when you will get equally good if not better crops by planting sound, whole, or even cut sets of medium-sized Potatoes.

Then, again, I see it constantly insisted upon as necessary to success "Change your seed;" "Get it from a distance if possible, and you will be repaid by double crops with greater immunity from disease." Now as far as my experience goes this is a mistaken notion. My advice is, If you have the chance save your own seed, and you will save your money too, and get a better crop into the bargain. "But this is rank heresy," some will say. Well, it may be so; but I can only add that for the last fifteen years I have purchased a quantity of seed, but never yet bought any as well saved as I can save it myself, nor any that gave me a better return in the way of a crop. I have now some Gloucestershire Kidneys (one of the very best earlies), which have been grown in and saved from the same ground for the last fourteen years, and their produce is this season quite equal to what it was originally; nor is there any more tendency to disease than there was at first. In fact, in the worst seasons I have usually had them quite free from it.

But when I say "Save your own seed," I mean "save it well." Let medium-sized tubers be carefully selected; let them be carefully spread out in single layers, and the original sprouts carefully preserved. And does all this ward off disease? No, by no means, but without doubt it mitigates its severity, and, above all, gives the crop a chance of being ripe and out of the ground before the pest appears. My experience coincides with that of Mr. Edward Luckhurst when he says that in the matter of disease we are at the mercy of the weather. It is simply a question of a wet or dry season.

Like many others I have gone in largely for Scotch Champions this season. I regret to say that my experience leads me to write myself among the fools for so doing. Not that I do not intend to try them again, for it is never fair to judge of anything finally from one season's trial. But at present I have several faults to find with them. First, they do not resist the disease as I was led to believe. On the contrary, my Champions were the first affected by it, and from them it spread to Snowflake in the same field. The disease is not of a bad type; but still the point is, that they have broken down in what was said to be their great forte. On lifting there were more diseased tubers than under most of the other varieties grown here. Secondly, the haulm is too long. I think it a great mistake to grow Potatoes with such immense stalks as Champion and Magnum Bonum have, if it is possible to get a crop from any others. We cannot eat Potato stalks. But the stalks can and do scourge the ground most unmercifully, and eat out a quantity of material out of all proportion to the useful part of the crop; besides, they take up so much room. Thirdly, they produce a perfect wig of fibrous roots; these added to the immense stalks make them hard to lift. Here they had to be cut off with a sickle like corn before the roots could be got at, and

when found they took a deal of digging. Fourthly, the crop is nothing wonderful considering the haulm. The tubers are ugly, hollow-eyed, and boil yellow. However, I do not so much mind the colour, and consider them superior in quality to *Magnum Bonum*. It is possible that when the seed has been home-saved they will do better. My man says (and I am quite sure that he thinks he knows much more than I do about Potatoes) they must have poor soil and no dressing, and then they will produce enormous crops. I hope this may be so, but am on the look-out for more fallacies.

Now, I think, for the present you will say that this is enough. Perhaps on some future occasion you will allow me again to keep the Potato pot a-boiling.—R. W. BEACHEY.

GLEANINGS AMONGST ROSES.

THERE has been no Rose harvest proper this season so far as I have heard and seen. Devastated, and in many instances totally destroyed, by the severity of the last two winters and springs, the ravages of the frosts and east winds have naturally been more apparent this season than last summer. The numbers of gaps, empty corners, and spaces everywhere, together with the weaklings that have been given another chance of bloom, make a mournful contrast to the memories of other years, when one could gather basketfuls rejoicing for home use or for some beneficent purpose where beauty and fragrance are so prized.

Up to August 1st, when the hot bright weather set in, it was difficult to cut any good Rose blooms. I never remember them in worse condition. Even the dark Roses, which usually resist wet, did very badly, and spotted and mildewed almost as extensively as the higher varieties. Almost all the dwarfs of the standard exhibition varieties which were put in last autumn did well—one only died. *Marie Baumann* bloomed grandly and profusely; and I note this the more particularly, that at the time of planting one plant of this Rose was so much mildewed—apparently quite withered, that we thought it dead. It has done the best in point of size and healthfulness. All these dwarfs were late in flowering. *Madame Emma* All does not show a bud yet. *Capitaine Christy*, *Madame Marie Finger*, *Marie Louise Pernet*, the latter a rich Rose of noble carriage and exquisite scent, gave large and perfect blooms. *Princess Beatrice*, an old plant, was very fine; another put-in in autumn died. *Horace Vernet*, *Fisher Holmes*, *Miller Hayes*, *Madame Victor Verdier*, &c., succeeded well.

It was amongst the old and autumn-planted standards that the havoc was greatest. *Mabel Morrison*, *Eugénie Verdier*, *Comtesse de Serenye*, *Louis Van Houtte*, *Lord Beaconsfield*, *Comtesse de Paris*, *Duc de Montpensier*, *La France*, *Duke of Edinburgh*, *Mons. E. Y. Teas*, and many more have left empty spaces or are replaced by *Stocks*, *Petunias*, or other temporary bedding plants. *Dupuy Jamain*, *Marguerite de Brassac*, *Abel Carrière*, and one or two others, including *Etienne Levet*, this last dwarf, are only now coming into bloom. Taking the standards old and new there are very few perfect heads to be found. Some, of course, are out and out vigorous and promising, but many are weakly and seraggy, and must be removed when blooming is over. *Beauty of Waltham* is certainly one of the hardiest, earliest, freest, and latest; very sweet, and a rich deep cherry red.

Amongst the newer varieties of dark Roses *Sultan of Zanzibar* deserves mention. A young standard put in the year before last and cut closely in this spring has done remarkably well, and I should think would be valuable as a climber. It is very free, and its dusky foliage is rich and handsome. I have just measured two shoots from the base of the budded part that broke late, and have in a few weeks made, one a growth of 68 inches, the other 60 inches. The dwarf *Sultans* are not remarkable for growth, but some other dwarfs, where they have successfully struggled against adverse influences, have made very strong growths. The general result seems to be that the Rose season has been late, irregular, and scanty, but it will probably be prolonged as some compensation.

As to weather, August brought us fourteen days of unclouded sunshine and high temperature. This was followed by a week of north-east wind and hardly any sunshine, both together most favourable for harvest operations and most beneficial to gardens. Yesterday, the 25th, the clouds gathered, the wind changed, and at 7.30 A.M. this morning we had a very high temperature, distant thunder, and deluges of rain. Soon after noon it began to clear; the sun has shone out, but it looks still unsettled. Nevertheless, untold good and goodness have resulted from the propitious weather of the last three weeks.—A. M. B., *Mid-Lincoln*.

CATTLEYA CRISPA.—Mr. Lane's note (page 140) on my plant of this *Cattleya* referred only to the number of blooms on the

plant when he saw it. Before this some had decayed and others been cut. I do not know the total number of flowers this year, but last year there were 132, and I think I must have had more this year, but the plant did not make so grand a show, as it has always previously expanded all its blooms at once instead of having an interval of nearly a month between its earliest and latest blooms, as this year. I may add that it is not now in my possession, as my hothouse was not large enough to accommodate it.—H. T. FRERE, *Burston Rectory*.

FRUIT CROPS.

SO much have the effects of the late severe winters and the almost sunless summer of 1879 been felt by vegetation generally, and the fruit crops in particular, that we have had in the gardening periodicals almost unvarying reports of general scarcity. There is no doubt that this year's crops are, as was anticipated last autumn by several of your valued correspondents in the *Journal*, very far indeed below the average. The later and colder the situation the more this will naturally be observable. We might consequently expect in localities more favourably situated as to climate a corresponding, or at least a partial, immunity from this scarcity. I think it would be interesting to many of the readers of the *Journal* besides myself to know if this reasonable expectation is at all borne out by facts, and the effects of exceptional seasons alleviated by certain local circumstances which ought to be stated by correspondents, so that the cause and effect may be recognised, and, if possible, information drawn therefrom.

In mild winters the variation of temperature between north and south, or between districts with wet and those with dry subsoils, may be about the same as in a severe winter. In a mild winter, however, the difference is perhaps more noticeable, as we may have just sufficient frost to check any premature starting into activity of the buds of fruit trees in a cold situation, while in a warmer one, the temperature being above the freezing point, this premature starting is not checked, and is frequently the cause of loss of fruit by spring frosts; for unfortunately these are not confined entirely to cold and late districts, but are frequently as destructive in early localities. Of the ill effects of wet sunless summers, such as that of 1879, there can be but one opinion; but severe winters may, and under certain circumstances it is my opinion do, conduce to the advantage of the fruit crop.

After an experience of seven years on naturally well-drained land in Glamorganshire, I can testify that however much we have suffered in ornamental and other departments from the frost, the fruit crops have been most plentiful after severe winters, the fruit blossom being too early after mild winters. If the rainy summer of last year draws the attention of cultivators to the more effectual drainage of fruit borders combined with shallow planting, its experiences will not have been endured in vain. Only by heavy drainage—excessive I had almost said—can a crop of stone fruits be insured in the season succeeding a wet one. This drainage if thoroughly done may occasion much labour in watering during dry seasons, but where can we find unmixed good in any operation?

As bearing out the opinion expressed earlier in these notes that severe winters are in some cases in favour of the fruit crops rather than otherwise, and as illustrating the power of shallow soil and heavy drainage to reduce the ill effects of much rain and little sunshine, I may state that stone fruits, especially Peaches and Apricots, were very plentiful and fine in size with us last season, but the less said of flavour the better. Last autumn the wood of Peaches seemed unripe, although better than might have been expected, and the bloom proved thin on most trees, but still there is again a fair crop; indeed, trees of *Red Magdalen* and *Noblesse* are carrying heavy crops. Of *Neectarines*, a tree of *Brugnon* (an old variety too seldom seen considering its good qualities) is carrying a full crop, while others are more noticeable for the size of fruit than for quantity. Apricots are very plentiful, more being borne by the trees than is perhaps good for them in spite of repeated thinnings. Plums are just as numerous, especially the *Gages*, *Kirke's* and others of the finer dessert varieties; even trees of *Transparent Gage*, which I have always found succeed but poorly, are loaded with fruits. Cherries of the sweet section and *Morellos* are equally fruitful. Pears, however, have been almost a total failure with the exception of *Jargonelle*, which is the only variety carrying a crop, and those the wasps seem determined to have. How is it to be accounted for, that after such a season as the last, when scarcely a wasp was to be seen, we seem invariably to have a perfect plague of them? Over ninety nests have been destroyed by the garden men in our immediate neighbourhood, yet there seems no abatement, so that sweet traps and hexagon netting are in constant request. Small fruits have been plentiful, as are also Apples in gardens, but thin in orchards.

I find that the larvæ of the Apple Clearwing are again commencing their boring operations on Apricot branches this year, much in the same manner as noted by me in the Journal last autumn. Most of the branches then spoken of as attacked started into growth in the spring, then suddenly withered and died as only Apriote branches can go. In two cases branches died on which I had not observed their operations, but on cutting them out I found small holes from which the perfect insects had emerged; so in my case at least I am more convinced than ever that the points of attack and death of branch exactly coincide. But I am inclined to think it must be a different species from the one usually frequenting Apple and Pear trees, for although many of each are grown in the garden none have been attacked. I kept several of the grubs in pieces of the bark all winter for the purpose of more certain identification on the emergence of the perfect insect, but on examination this spring I unfortunately found them shrivelled and dead instead of changed into the pupa state.—R. CROSSLING.

DISA GRANDIFLORA FROM SEED.

As some persons are desirous to learn my method of raising *Disa grandiflora* from seed, it is perhaps as well to reply to them through the columns of the Journal.

The seed should be sown as soon as it is ripe; but if that does not happen until late in autumn it would be safer to postpone the sowing until the following September or the last week of August. There are two modes of sowing the seed, each of which has its advocates. One of them consists in sowing on living sphagnum in a pot or pan. The moss must be kept always moist, and this may be effected by constant and very gentle dews, as the danger of a regular watering as ordinarily understood is that the seed would be washed down too deeply. The other plan is to sow on a sod of turf, as we call it in Ireland, or hard peat, as you would probably understand it—I mean the peat as prepared for fuel. Let it be well soaked in water. Sow the seed thickly on its upper surface. Cover all with a bellglass, and place it in a cool, damp, and shady place. The turf must never become dry, but the spraying of water must be of the gentlest description. A good plan for watering very fine seeds is to dip a stiff-haired brush in water, and to draw the hand briskly against it at such a distance as that only the finest dew reaches the seed.

When the seedlings appear they must have more air. When they can be handled they should be pricked off into small pans, or into pots not less than 4 inches in diameter. The compost for the seedlings for the first two years should be somewhat similar to that for mature plants, only that the peat should be considerably finer for an inch or two on the surface, and a much larger proportion of silver sand is necessary. The after treatment as regards ventilation, situation, and water is similar to that for established plants.

While I am on this subject I would warn persons whose stock is limited to a plant or two not to be too anxious for seed. One pod on a healthy plant is quite sufficient, as seeding retards the autumn growth and recovery after the labour of flowering.—FREDERICK TYMONS, *Clk., Co. Dublin.*

SANDY AND DISTRICT HORTICULTURAL SOCIETY.

THE strenuous exertions of an active Committee combined with the advantages of a suitable site (the picturesque park of John N. Foster, Esq., Sandy Place), in a central and convenient locality in the Bedfordshire market gardening district, have tended to render the Sandy Show not only the county Show of Bedfordshire, but one of the most important in the south-midland counties. The weather on Friday last proving all that could be desired for a flower and poultry show, the latter fancy being also strongly represented, an immense gathering more than sustained the usual prosperity of this Exhibition. Corresponding with this growth of popularity the quantity and quality of the exhibits have also increased, except perhaps as regards the large show plants.

In the open class for ten stove and greenhouse plants the competition has for several years been limited to one trade exhibitor, Mr. Parker of Rugby, who on this occasion was as usual first with some of his fine specimens, among which were noticeable *Bougainvillea glabra*, *Clerodendron Balfourianum*, *Allamanda Schottii*, *Stephanotis floribunda*, *Lapageria rosea*, and *Dipladenia insignis*. Lieut.-General Pearson (Mr. W. Rabbitt), The Hasells, Sandy, was second with a collection containing fine specimens of *Eucharis amazonica*, *Begonia Vesuvius*, and a remarkable unnamed *Azalea* bearing three different well-developed types of flowers. In the class for six stove and greenhouse plants open to amateurs J. H. Goodgames, Esq. (Mr. G. Redman), Eynesbury, Hunts, was first, and J. H. Astell, Esq. (Mr. G. Claydon), Woodbury Hall, Hunts, second. For twelve Zonal Pelargoniums in the open class, cleaner, better bloomed, and more even plants than those from General Pearson's have rarely

been shown, the finest and most distinct of the varieties being *De Lesseps* and *Lord Gifford*, both first-rate scarlets; *Dazzler*, brilliant vermilion with a clear white eye; *Rose of Allendale*, purplish rose (an excellent bedder also Mr. Rabbitt informs me); and *Madame Vaucher*, which he states after trying a great many of the newer varieties he still finds the best of all the whites. For six foliage plants in the gardeners' class Mr. Claydon was first, staging good plants of *Croton Weismanni* and *Cissus discolor*. For six stove and greenhouse Ferns in the same class Mr. Claydon was also first, his collection being crowned by a grand specimen of *Dicksonia antarctica*. Some remarkably well-coloured *Coleuses* were shown by Mr. Rabbitt, who was first in this class.

For dinner-table decorations Miss Pearson of The Hasells, Sandy, was first with a light and elegant arrangement containing a good deal of neutral colour, and Miss H. Astell of Woodbury Hall was second, making a very attractive and cheerful display. For hand bouquets Mr. E. Lewis of Huntingdon was first, and Col. Duncombe (Mr. R. Carter), Waresley Park, second. In cut flowers Dahlias were creditably staged by the Rev. E. L. Fellowes of Wimpole Rectory, Royston, who also had some excellent Asters; but perhaps the most attractive stands in this department (Roses excepted) were some remarkably fine African Marigolds. A stand of twelve orange-coloured flowers as large as ordinary Dahlias was set up by Mr. Swanie of Arlesey, who was first. Mr. D. Sewell of St. Neots had also in his stand six lemon-coloured blooms almost equally fine. The French Marigolds too were also numerous and well shown. Amongst the various cut flowers Zonal Pelargonium Henry Jacoby stood out as a very dark and distinct coloured variety. Roses, considering the moderate prizes offered, were remarkably good. Messrs. G. Paul & Son of Cheshunt and Mr. J. House of Peterborough, both showed very fine collections in the open class for forty-eight blooms; indeed so evenly balanced were both stands that it must have been difficult for the Judges to decide. Messrs. Paul was ultimately placed first and Mr. House second, the latter having several duplicates, as the schedule did not specify distinct kinds. The Rev. E. L. Fellowes was third with fresh and highly-coloured blooms. In Messrs. Pauls' stand the most noticeable were *Mdlle. V. Verdier*, splendid; *Marquis of Salisbury*, a handsome flower of the *Emilie Hausburg* type, but somewhat deeper in tone and otherwise distinct; *A. K. Williams*, confirmed as a good autumn Rose; *Duc de Wellington*, *Marie Baumann*, *Exposition de Brie*, a very fine flower; *Maréchal Niel*; *Capitaine Christy*, very good; *Star of Waltham*, *Duke of Teck*, *Le Havre*, *Souvenir de la Malmaison*, *William Roelle*, and *Mdlle. A. Lavallé*, both promising as new Roses. Mr. House had first-rate flowers of *Marie Baumann* and *Alfred Colomb*, two perfect blooms; *Xavier Olibo*, *Duc de Wellington*, *Duc de Rohan*, *Pierre Notting*, *Dr. Andry*, *A. K. Williams*, and *Mdlle. Jeanne Bowyer*, a broad-petalled cupped variety between *Comtesse d'Oxford* and *Victor Verdier*. Amongst Mr. House's "spares" was also a bloom of *William Allen Richardson*, which indicated that this new *Noisette* will become a popular variety for cutting, the colour being of the deepest orange-apricot, and both the petals and flowers having more substance and size than those of any other variety of the colour. Mr. D. Sewell of St. Neots had also a fine bloom of *Innocente Pirola* (Tea), and in Mr. Fellowes' stand was a good flower of *Amazone*.

In the fruit and vegetable tent an undoubted feature was the Grapes from Old Warden. In the class for two bunches of black, Joseph Shuttleworth, Esq. (Mr. Allis), Old Warden, exhibited magnificent fruit of *Gros Guillaume* of the richest colour and most beautiful finish; finer fruit of this variety and of *Buckland Sweetwater*, which Mr. Allis also staged, is seldom seen; he was first in both classes. Mr. T. W. Sheppard, Great Staughton, Hunts, who was second for black Grapes with good *Black Hambro'*, also showed a fine bunch of *Lady Downe's Seedling*, not for competition. For two bunches of white Grapes Mr. Redman was second. Bateman Brown, Esq. (Mr. Tillbrook), Houghton, Huntingdon, was first for a basket of fruit (Pines excluded) not to exceed 2 feet by 1 foot 4 inches, a limit of space evidently very unsatisfactory for the exhibition to advantage of a good collection of fruit. Transparent Gage Plums and early Julian Apples were also shown well, but with these exceptions the fruit was not remarkable.

Vegetables, as might be premised, were, on the contrary, of the first quality at Sandy; and although not of the *recherché* character nor set up on the gigantic scale as seen at Cheltenham, a larger and better display of ordinary vegetables is rarely met with at a provincial exhibition than here. For the collection of eight varieties *F. Howard*, Esq. (Mr. Geo. Robinson), Abbey Close, Bedford, was first; Mr. R. Facey, Goldington, Bedford, second; and H. Thornton, Esq. (Mr. G. Vyne), Kempston Grange, Bedford, was third, all showing very clean collections. For six varieties Mr. J. Armstrong, Goldington, was first, and Mr. J. Hills of the Bedford Sewage Works second. The best brace of Cucumbers, very even and without shoulder, came from Mr. Rabbitt, the variety being *Tender and True*. For a collection of Potatoes, six varieties, Mr. J. Richardson of Boston was first with *Rector of Woodstock*, *Baker Kidney*, *Beauty of Hebron*, *International*, *Myatt's Prolific*, and a handsome pink round variety. Mr. R. Facey was second, having fine tubers of *International*, *Magnum Bonum*, *Trophy*, *Pecrless*, *Manhattan* (round, dark purple splashed white). The varieties, however, which seemed to take the lead as winners throughout the Exhibition were *International* and *Magnum Bonum* as kidneys, and *Schoolmaster* and *Porter's Excelsior* as rounds.

Only slight signs of disease were apparent, and it is to be hoped that the recent dry weather has stayed its virulence. Celery was heavy and very good for the period. Onions were not so good as usual, many of the exhibits being soft and showing the effects of wet and mildew. Cauliflowers were rough, and not nearly so good as last year's exhibits. Peas, especially Omega and Telegraph, were well shown. In the cottagers' classes vegetables were quite equal to those shown by gardeners and amateurs, the collections staged by Messrs. J. Spencer and G. Johnson of Bedford, who were respectively first and second, being very creditable and clean.

Where advancing success attends an undertaking like the Sandy Show, which is well and systematically carried out, it would probably be injurious to make any material alteration, especially as the schedule is a liberal and comprehensive one; but as the Society has not only emerged from its infancy but has become an important institution since the schedule was originally framed, there is scope for a corresponding expansion in some of the divisions, and as the finances of the Society are also in a healthy condition there can be no reason why Pine Apples should not on a future occasion be recognised. The public are much indebted to the Honorary Secretary (Mr. E. T. L. Smith) and the Secretary (Mr. Green) for the quiet and business-like way in which the Show is managed, complaints and mistakes at Sandy being very exceptional. An immense concourse attended the Show, which combines poultry, farm produce, cage birds, and bees with horticulture, and I understand that the receipts were in excess of those in former years.—T. LAXTON, Bedford.

THE SHANKING OF GRAPES.

It is a singular fact that fungus is so often said to cause disease. The Potato disease has repeatedly been attributed to it, so has Peach blister, and now we are told that it gives rise to the shanking of Grapes. In every instance the idea is erroneous. Spores of fungi are so minute as to be invisible to the naked eye, and are probably so light as to be blown hither and thither by every current of air and deposited upon the surfaces of any plant with which they come in contact. Sooner or later the germs vegetate, and in most cases perish for want of a suitable nidus wherein they may flourish and attain to full development. The diseased epidermis of any part of the young and tender growth of plants affords this medium, hence when upon examination the affected part is found infested by fungi an outcry is raised that fungus precedes and is the cause of disease, when in my opinion it follows and is a mere result of it. The fact of the liability of delicate sickly human beings to suffer from infectious diseases, while those in robust health are untouched, is well known to medical practitioners, and the analogy which exists between plant and animal life should fairly induce similar conclusions on the part of horticulturists, and be taken for a guide in the treatment of their patients.—EDWARD LUCKHURST.

PERMIT me to say in my remarks last week the word "freshness" should read "fleshiness." Sulphur applied in any form does not exert the slightest effect upon the disease.—J. S. W.

EARLY RECOLLECTIONS OF FLORICULTURE.

I WELL remember when I first made my essay in gardening at eight years of age (1806) with my playfellow, but flowers were not in our possession, and we were content to grow Mustard, Cress, and Radishes in a plot of ground now surrounded by dwellings. Well do I remember buying my first flower plant, a Sweet William, for which I paid 2d., and shortly after my father purchased the goodwill of a small garden one mile from our dwelling, and then my love of flowers increased. At that age my pocket money would not do much; however, a neighbouring grower of Pinks aided me, and one day he invited me into his garden and gave me some cuttings. The only names I recollect in the Pinks was one named Midshipman, a red-laced variety; and Davey's Eclipse, a black and white variety; and year after year additions were made by seedlings. Faulkner raised a purple-laced Duke of St. Albans, one that for some years was able to keep all varieties at a distance until the Duke was surpassed by others in 1807. Few florists could cultivate any other varieties, as the price enabled a working man to spend his few shillings in what from circumstances he was compelled to grow. A few who had trades that enabled them to earn good wages bought a few of the low-priced Auriculas, and in course of time they made a gay appearance in their gardens.

In Lancashire (Middletown) the men were principally employed as weavers, and added to their stock. If possessed of forty or more plants they were considered to have a collection, and several who were noted for their knowledge of them were written to, to supply growers in the south and other parts of England with plants. Years elapsed before the largest growers could have a

collection amounting to 150. There are only a few growers now, as the manufactories have polluted the atmosphere, and Polyanthuses and Auriculas will neither grow nor flourish except in the purest of atmospheres. Pinks from a very early period were considered the poor man's flower. He could purchase a pair of plants for from 2d. to 2s. 6d., and at that period they were poor worthless things. Cultivation did all for them, and as they were in a manner semi-double and produced seed very freely, a great number of seedlings were annually raised. A gradual improvement took place, and instead of serrated petals a few rose-leaved occasionally appeared, until at last a rapid stride took place. A variety raised in the south named John Ball, a red-laced variety, supplanted all, taking for years the first prize, but I understand John Ball has now to play second fiddle.

Auriculas made but slow progress, and but few good varieties were raised from seed. I do not know a flower that produced such poor varieties for years, and even now few that are equal to the old forms are rarely to be seen. Gerard in the year 1597 does not give much information respecting them. I have made very strict inquiry at times, and but little is known respecting them. The growers were illiterate men and could scarcely write their names. The earliest period known when Auriculas were grown in Lancashire was 1725. The earliest Auricula show was held at Eccles, four miles from Manchester, in 1780, and it was afterwards removed to Middleton near Manchester, having a fixed time for showing—viz., 20th of April. The oldest variety exhibited was in 1757, called Rule Arbitrator, green-edged, and from that period to 1831 few additions were made. Lees' Colonel Taylor, green-edged, was first shown in 1831, and for many years maintained a first-class position; Taylor's Glory, white-edged, was shown as early as 1821; Booth's Freedom, green-edged, was exhibited in 1841; and Page's Champion in 1851. Lancashire's Lancashire Hero was first shown in 1852, and from some altercation was sold to Cheetham of Rochdale, and he then sold out as if he had raised it. My situation became so vitiated that I was compelled to cease growing Auriculas about that time.

Tulips were great favourites with me, and I grew a worthless lot until I became a favourite with one of the oldest and best of our local growers. I had £3 given me to spend with him, and he selected for me Incomparable Reine de Perse, 20s.; Rose Unique, 15s., now can be had for 3d. or 6d.; Maître Partout, now discarded; Gond Beurs also, and Gold Mount, not known now. He made me a present of a great quantity of offsets, and when they grew into bloomers there were a great number of a variety called Duc de Savoy, and being of a good strain I sold them readily at 1s. 6d. each, which money was laid out in other varieties, and by that means I obtained a collection something like what my neighbours were growing. We had but few English-raised varieties, and the Dutch being the only possessors of them they charged enormous prices.

In England, Bethnal Green was then considered to have the most numerous growers, and few possessed more than a small bed from 1 to 4 yards long. This went on for some time, until a gentleman of means who lived at Croydon turned his attention to raising seedlings, and no grower has ever been so fortunate as he was, and even now some of our finest varieties are of his raising. Influenced by his success many of our lovers of the Tulip began to gather seed and sow it, and a few were successful. It must be borne in mind that taking seed promiscuously is generally a loss of time; and there is an old saying, that if you raise five hundred seedlings you will be lucky if you obtain one good one, but by taking seed only from the best and choicest varieties we have distanced the Dutch, and they have but few that will take rank with ours. The Chellastons as they were called being raised by one Gibbons, who resided at that place, made a great noise in the floral world, and although they numbered 350 varieties, scarcely any of them are now ever seen at an exhibition. Others tried their skill on a small scale, and have now enabled us to be classed as having the finest collections in the world, and they can be purchased at very reasonable prices.

The last catalogue which I saw from Holland contained a very small number, many of which have long since been discarded from our collections. I have raised a few, some of which sold at the price of £5 per root. It was always my aim to take seed from first-class varieties, and also by crossing them I seldom had many to discard. I again caution those who are desirous of raising something that will stand for years and take a place at an exhibition, to be always careful in selecting seed.

The Pansy is one of our flowers which from a weed has become a most beautiful flower, and shows how much can be done by cultivation. Good seed will generally produce some good varieties. I remember well one of the first coming out at 10s. 6d. each plant, that would now be considered as not worthy a place in any col-

lection. There was quite a rage for this flower at one period, and I have had 5s. each given me for cuttings. I also remember them being first exhibited at our Society, and 21s. was given for the first prize, and 1s. for the one placed tenth in the class. They are but partially shown at present, and in collections of six, twelve, and twenty-four, and only a few shillings for each prize. I am a great admirer of those raised in Belgium, some of which are very beautiful. There is no flower that sports more from seed than the Pansy, even from the best seed you will have many no better than the original. It was in 1828 I was induced to persevere in raising Pansies, and by so doing I in a few years had a collection second to none.

Floricultural novelties were the order of the day. Lady Holland introduced the Dahlia, which at first was only semi-double. I purchased two roots at 15s. each, and the blooms only consisted of seven petals. A few years elapsed and a double variety was produced, said to be raised by the gardener at Crowcroft, a little more than three miles from Manchester. After a time another improvement took place in one called Springfield Rival, which was a decided advance upon any then raised. Dahlias were in the ascendant for some time, and from various statements many that were worthless introduced. In 1844 only eighteen varieties were catalogued, and in 1845 only eight varieties were thought worthy of being grown. In 1847 there was catalogued seventy-two varieties, and in 1849 out of these only fifty-seven were considered worth growing, and in 1852 they had not increased very much.

Fuchsias.—When in 1828 I grew a few plants in my cottage windows there were only *Fuchsia coccinea* and *Fuchsia gracilis*. The next improvement was *F. glohosa*, then *F. exoniensis*, and I leave it to those who now grow them to speak as to their present improvement. Having obtained the two Fuchsias mentioned I had space for more plants, and in 1828 the only Geraniums, now called Pelargoniums, were a variety called Davyana, a dark ground; and *Macranthon*, one with a white ground and a blotch eye. In this class of plants the improvement is really wonderful. To Messrs. Foster, Hoyle, Beck, and Turner we are much indebted. I have never seen latterly any that are much in advance of what were grown a few years back, excepting those called French varieties.

Carnations and Picotees were early grown and exhibited, but with the exception of Carnations the Picotees were worthless, and only a degree removed from the originals. A variety called John's Prince Albert was the pioneer of our beautiful specimens. It was a prolific seeder; and Ely of Rothwell Haigh, near Leeds, who was one of our most enthusiastic growers and raisers, took advantage of its seed-bearing properties and raised Field Marshal and others in advance. Other growers also added to the number, and they have so much improved that it is scarcely possible to advance further. Mr. Charles Turner, Mr. Dodwell, and Mr. Simonite of Sheffield have done much for them.

A notice of the exhibitions in 1830 will no doubt be interesting, as Mr. William Smith and myself were the two acting Secretaries, and Mr. Barber the Honorary Secretary of the Manchester Floral and Horticultural Society which had been a few years in existence. Its revenue for several years amounted to upwards of £500 annually, and was devoted to the improvement of all classes of plants and flowers then known. Its schedules were far different from what they are now, and had a very great tendency to encourage growers. The Polyanthus and Auricula shows were generally held in April, and the flowers were shown in classes; eight and sometimes ten prizes were offered in each, the first prize ranging in value from 21s. to 10s., and the last prize 1s. For stove and greenhouse plants 21s. was the first prize, and the tenth 1s. Single plants only were shown, not as now twelve or six plants. Fruit and vegetables were not forgotten, and any new introduction was not left unnoticed. At these Shows I only recollect the exhibition of one Orchid, *Oncidium papilio*, and few collections were in existence.

Exhibitions have now grown to such magnitude that only those who possess large houses and plants can compete in the principal classes, and the cottager has generally to content himself with the enjoyment of his humble collection at home.—JOHN SLATER.

PLANT PORTRAITS.—Last April Sir Michael Hicks-Beach transmitted to Mr. J. Gordon Sprigg, Colonial Secretary at the Cape of Good Hope, in a circular dispatch that was at the same time addressed to the other colonies of South Africa, Australia, New Zealand, and the Mauritius, a copy of a letter from that zealous botanist, Sir Joseph Hooker, K.C.S.I., C.B., notifying the purpose of an accomplished artist, Miss Marianne North, to visit those parts of the world, and, with the aid and counsel of scientific authorities resident in the several districts, to make faithful pictures of remarkable trees and plants, for presentation to the

Royal Gardens at Kew. These works of botanic portraiture are intended to complete a series in which the lady had made considerable progress, inasmuch that, before her departure, the collection already included hundreds of views which she had taken in the East and the West Indies, Brazil, Java, Ceylon, Borneo, Japan, North America, and the Canary Islands. The great importance of that labour of love which Miss North has undertaken at her own cost can be best appreciated by those persons who, in commercial, educational, and industrial pursuits, have felt the want of a comprehensive and accurate source of pictorial reference, especially in relation to the Gum Trees of Australia, the Pines of New Zealand, and the Aloes and Heaths of the Cape Colony, which, together with all the peculiar, varied, and beautiful flora of South Africa, have hitherto lacked efficient illustration.—(*Daily Telegraph*.)

SOUND AND DISEASED POTATOES.

IN these days of anxiety respecting the Potato crop most of us who are sufficiently interested in the matter are glad to read the reports from persons writing from all parts of the kingdom. I therefore offer the results of my experience. Last year I planted Myatt's Prolific and Dalmahoy's; my crop of sound Potatoes scarcely exceeded the seed planted. This year, at the beginning of March, I planted Myatt's Prolific and Sutton's Magnum Bonum. The early variety is much diseased, but the others—Magnum Bonums—have turned out a splendid crop, large, sound, and bright-skinned; in fact my gardener and an old man he had to assist him are of opinion that they never before dug up such a fine crop of sound Potatoes. The garden soil is a porous sandy loam, which never appears sodden after the heaviest rains. The two varieties were grown close together, and treated in every respect alike, and yet with what different results!—W. G., *Elmdale, Sutton, Surrey*.

SALTBURN FLOWER SHOW.

ALTHOUGH this is but the third Exhibition held here it promises by its rapid advancement to become one of the best exhibitions in the north. The site selected is an admirable one, being contiguous to the pleasure grounds of the Saltburn Improvement Company, the grounds being situated in a ravine, with beautiful undulating surface with a stream of good width at the bottom. The grounds are tastefully laid out, long walks shaded by overhanging trees, others open, with flower beds showing great taste in the arrangement, there being a great variety of trees and shrubs both evergreen and deciduous, Roses, and hardy plants; indeed, there is everything calculated to afford enjoyment. The woods and pleasure grounds of Rushpool Hall adjoining were, with the customary kindness of the proprietor (Mr. Bell) also open to visitors. The weather (August 19th), though threatening in the morning, cleared up fine by noon, and remained so, contributing greatly to the success of the Exhibition. The arrangements of the indefatigable Secretaries, Messrs. Adamson and Burn, were very satisfactory.

The show of stove and greenhouse plants was rather extensive, the plants being large, well grown, and splendidly flowered. For six plants in bloom Earl Zetland, Upleatham Hall (E. H. Letts), was first with *Stephanotis floribunda*, about 4 feet high and nearly as much through, and finely bloomed; a specimen of *Erica insignis*, over 4 feet across, and well flowered; *Bougainvillea glabra* of similar size, the bracts being highly coloured; *Allamanda Hendersoni*, finely flowered; a remarkably healthy and profusely flowered *Erica Fairreana*; and *E. ampullacea* Williamsi. A close second in the same class was H. Pease, Esq., Pierremont, Darlington (W. Yule), with a magnificent specimen *Eucharis amazonica*, with over fifty scapes, and five to seven flowers each. Third honours were taken by E. W. Swan, Esq., Middlesbrough (Alex. Kevan, gardener), with neat specimens. For six variegated or ornamental-foliage plants Mr. Letts were again first with grand specimens of *Croton Wiesmanni*, *Gleichenia rupestris glaucescens* in capital health; *Dasyliion acrotrichum*, *Chamærops humilis elegans*, very fine; *Dion edule*, and splendidly coloured *Croton Johannis*. Mr. Yule was placed first for three with well-grown plants of *Pandanus Veitchi*, *Areca sapida*, and a *Dracæna*. In the class for three exotie Ferns, equal first prizes were awarded to Edmond Grove, Esq. (Mr. J. Rutters), Saltburn, and Mr. Alex. Kevan, the former having plants fully 4 feet through of *Adiantum gracillimum*, *A. farleyense*, and *A. cuneatum*, the latter having equally large and fine specimens.

Table Decoration.—Table set for ten, with flowers, fruits, glasses, napkins, &c., à la Russe. First honours were secured by Mr. Letts, the arrangement being very light, chaste, and elegant, having a neat plant of *Cocos Weddelliana* in a centre, with a ground of *Selaginella apoda*, sprinkled with *Lapagerias* and *Roses*, the lower fronds of the *Cocos* supporting fine spikes of *Odontoglossum vexillarium*; the ends were glass epergnes or stands with *Lapageria alba*, *Odontoglossums* and *Roses*, Maidenhair Fern, and vases of *Lycopods*. The fruit comprised Grapes, Peaches, Figs, Strawberries, Melon, and Apricots. Mr. S. Taylor (Wm. Mann), Brotton Grange, was a close second with a very effective centre of choice flowers displayed in a glass stand,

and neat plants of *Reedia glaucescens* at the ends. The fruit comprised Pines, Grapes, Peaches, Pears, and Melons. Bouquets were in strong force, Mr. Richard Parker, Guisbro', being awarded first prize for a wedding bouquet, very tastefully composed of *Eucharis*, *Stephanotis*, *Jasminum grandiflorum*, white *Erica*, and *Lapageria alba*. The same exhibitor also took first for a ball bouquet.

Dahlias were in strong force. For twenty-four dissimilar blooms Mr. R. Harkness, Bedale, was deservedly placed first with blooms of great size, fine form, and purity of colour. The varieties in this grand stand were Vice-President, James Cocker, John N. Reyner, John Wyatt, The Countess, Flora Wyatt, Louise Neate, Henry Walton, Julia Wyatt, Hon. Syd. Herbert, Mrs. Stancomb, Seedling, Delicata, Dr. Moffatt, John W. Lord, Royal Queen, Bessie Lord, James Service, Royal Purple, Harry, Cremorne, Thos. Goodwin, Countess of Pembroke, and Chris. Ridley. Second, H. Clarke, Rodley, Leeds, with capital blooms of great size and purity of form and colour. Mr. Boston, Cawthorpe, Bedale, was a good third with large blooms. In twelve the above-named exhibitors changed places, Mr. H. Clarke being first and Mr. Harkness second. For twelve Dahlias, fancy varieties, Mr. A. Clarke was placed first with admirable blooms of Octoroon, Eccentric, Singularity, Egyptian Prince, J. B. M. Camm, Gaiety, Flora Wyatt, Mrs. Saunders, Tipy Bob, and Charles Wyatt. Mr. Boston was a good second. Hollyhocks since the disease are somewhat scarce. Mr. Boston staged an excellent stand of twelve varieties, remarkable for compactness, substance, and colour; Mr. H. Stairmand, Eastbourne, Darlington, having a grand lot of blooms, and was placed second.

In the class for Roses, eighteen varieties, Messrs. Mack & Son, Catterick Bridge, took first prize with handsome blooms of Madame Hansman, Madame Thérèse Levet, Comtesse de Serenye, Madame Charles Wood, Marquise de Castellane, Star of Waltham, Marie Verdier, Marie Rady, Marie Finger, Alfred Colomb, François Michelon, Baroness Rothschild, Emilie Hansburg, John Stuart Mill, Maréchal Niel, Duchesse de Vallombrosa, and Marguerite Brassac. Mr. Harkness was a good second. Twelve varieties cut flowers, were well shown, Mr. Letts taking first prize with fine examples of *Lapageria rosea*, *Stephanotis floribunda*, *Bougainvillea glabra*, *Allamanda Hendersoni*, *A. grandiflora*, *Anthurium Schertzerianum*, *Statice profusa*, *Dipladenia Brearleyana*, *Eucharis amazonica*, *Ixora Williamsi*, *Lapageria alba*, and an *Erica*. Mr. Yule was a close second. Mr. Edmondson Fletcher, Charlestown, Baildon, Leeds, was first with Asters, beautifully quilled, and the same exhibitor took first place for twelve French Marigolds, grandly striped. For six Gladioli spikes Mr. Harkness was far ahead of all competitors; also for three. In addition to the preceding were an excellent display of other cut flowers, making a display which was much admired.

Fruit was excellent for the season; what was lacking in quantity was amply compensated for by the quality of the productions. For a collection of six varieties (Pines excluded), the first prize went to H. O. Norwig, Esq., Grove Hill, Middlesbro' (Mr. T. Hanson), with magnificent bunches of Duke of Buccleuch Grapes, the bunches being little short of 3 lbs. weight each, very symmetrical in shape, berries large and faultless in every respect. Black Hamburg Grapes were shown large alike in bunch and berry, splendidly coloured, and well bloomed; *Violette Hâtive* Peaches, good; Lord Napier Nectarine, large and well coloured; Greengage Plums, fine; and a finely netted Golden Queen Melon—altogether a collection of great merit. Mr. S. R. Jowsey, Ledbury Park, Richmond, Yorks, had a capital collection, especially Grapes, and was placed second. For two bunches of black Grapes Mr. Aitken was first with Black Hamburg, two bunches over 3 lbs. each—very fine berries and beautifully coloured. It may be worth mention that the Grapes were cut from a Vine carrying 125 bunches of similar size. Second honours were taken by Mr. C. Hockney with fine examples of Black Hamburg. For two bunches of white Grapes Mr. Jowsey was first and Mr. W. Mann second. The first prize for six Peaches went to Mr. Jowsey for Royal George; and the second to Mr. J. Shepperd, Preston Hall, Stockton, for Grosse Mignonne.

Vegetables were never in better quality than at this Exhibition, the prize list being a liberal one, and brought a legion of competitors. For a tray of eight distinct varieties Mr. John Snowdon, Thirsk, was first, having splendid Tripoli Onions, Negro Kidney Beans, International Potato, Telegraph Peas, Excelsior Tomatoes, Veitch's Autumn Giant Cauliflower, and immense heads of Celery—a really good collection. For a brace of Cucumbers Mr. Arthur Whitten, Arkern, was first with what appeared to be Tender and True, but very few varieties were named either in fruits or vegetables. Cauliflowers were very fine, particularly those taking first prize, from Mr. R. Bean, North Skelton. In Tomatoes Mr. W. Lawrenson was first with Criterion, and Mr. W. Russell second with Excelsior. Potatoes were in splendid condition and in great quantity. For twelve kidney Potatoes Mr. C. Hockney took first with International; whilst for twelve round Mr. W. Mann was first with excellent examples of Porter's Excelsior.

The cottagers' productions were extremely fine, the principal exhibitors affording undoubted evidence of their skill as cultivators of the most useful of garden produce.

For six plants for table decoration grown in 6-inch pots, Mr. W. Yule was first with *Cocos Weddelliana*, *Geonoma gracilis*, *Aralia leptophylla*, *Pandanus Veitchi*, *Kentia Wendlandi*, and *Aralia gracilima*, the prize being books, value 21s., given by Mr. B. S. Williams. A further special was given for six tuberous-rooted Begonias, and was

taken by Mr. Short, Stokesley, with seedlings of his own raising, Electric Light being an intense fiery scarlet, with very large flowers, well on to 6 inches across—an exceedingly fine variety. Mrs. Short was very good, also *Fimbriata*, *Magentiflora*, and T. B. Morton; the other unnamed but very good. Several other special prizes were given, which added much to the extent and variety of the Show.—G. ABBEY.

MEALY BUG IN VINERIES.

I WAS glad to find from your issue of the 12th ult. (see page 138) that someone was free from this pest, and I wish I could say I had entirely stamped it out. I cannot agree with your correspondent "R. M.," that a vinery badly infected with bug can be cleared in a single season. When the insect is amongst the drainage how would "R. M." destroy it? If plants are not placed in vineries it may greatly be reduced, but I fear "R. M." would fail in his first attempt to thoroughly eradicate it. The practical article from the "Gardener" in the same issue, points in the opposite direction. I have tried everything to stamp out this pest over a series of seasons before thoroughly accomplishing it. If I have been working wrongly, "R. M.'s" advice, with more minute details of his system, would have proved of great advantage long ago to others besides myself. I have had mealy bug to contend with in quantity during the past few years. How it entered the vineries is not a question for me to decide. I found it there and started in earnest to exterminate it. All infested plants have been kept out, and softwooded plants that could be propagated easily were thrown away, and clean stock started. So far I have failed to destroy the bug as quickly as "R. M.," but labour and trouble have not been spent in vain.—WM. BARDNEY.

FORTUNATELY I have never been troubled with this pest on Vines, but have had quite enough experience of it on plants and Peach trees. I believe I am now quite free of it, not having seen one for three months. For the last three years I have been waging war against it, and believe I have now vanquished the enemy. Two Peach houses were so infested with it that dressing the trees in winter was useless till I adopted the plan of washing the trees and trellis with benzoline, and as the eggs which were not destroyed hatched out, and the bugs were visible, I touched them with a feather dipped in benzoline; the result has been so satisfactory that I have not seen one insect for at least three months. I followed the watching daily for several weeks until not one could be found. Now the two houses, each 50 feet long, will bear inspection by the keenest eye. Where the spirit could not be readily applied, or there was any suspicion of the enemy sheltering under crevices, a little spirit was dashed in, a light applied, and literally burnt them out. The result is so satisfactory that nothing else will be used by me should I need it, which I hope I shall not. The remedy is safe, simple, and cheap, as all who are plagued with either mealy bug or scale will find if they make use of it that it is effectual.—JOHN GADD, *Thorndon*.

MESSRS. VEITCH'S SEED FARM AT SLOUGH.

HAVING been deprived of their trial grounds in Fulham by the railway company, the Messrs. Veitch have removed this important branch of their business into more distant and decidedly more roomy quarters. About half way between Langley and Slough, on the Great Western Railway, they have procured by purchase some 50 acres of land in the parish of Langley, which, though necessarily somewhat rough at present, is rapidly assuming under the able management of Mr. J. Newby, late of St. Osyth, a neater and more presentable appearance. After the dingy brickfields which continually meet the eyes of travellers the whole of the journey from Sonthall to Slough, a peep at the rich and varied colours in the grounds of Langley Farm affords a change at once agreeable and refreshing. Visitors to the farm may alight at either Slough or Langley, but the former station is preferred, as conveyances may be hired for the convenience of those persons who wish to avoid a tiring two-miles walk along the dusty road, which has to be traversed before the grounds are reached. Once there, however, the troubles of the road are soon forgotten in the admiration engendered by the glowing masses of colour which the farm presents.

Mr. Newby first takes us to see the vegetables, and points out to us about an acre of Parsley, from which every plant of doubtful quality has been removed. This is a selected form of Myatt's, and is seeding well. In another part of the farm is a similar piece of the Fern-leaved variety, which some people prefer. Next comes about an equal quantity of Broccoli, Lauder's Goshen, a fine late white variety, which Mr. Newby is very careful to keep true. Again, as widely distant as possible, is similar breadth of the valuable late variety Model, of which the demand is great. Other sorts

are also grown, all widely separated. All the Broccolis are grown of their full size for seeding, and every plant rejected that shows the slightest variation from the standard type. A very large breadth of Veitch's Red Globe Turnip will, it is expected, secure seed for all applicants, many of which have hitherto been disappointed in obtaining a supply of this fine variety. The extensive breadths of Beet tell how great is the demand for this vegetable, Nutting's Selected being the most popular of all, and consequently grown in the largest quantity. Seakale is in abundance, and the supply of roots for forcing will, according to present appearances, be both plentiful and good.

Of Potatoes, all are more or less affected with disease with the single exception of St. Patrick. Prince Arthur, however, a fine variety, which received a first-class certificate from the Royal Horticultural Society, was but slightly touched. Early Rose, Grampian, Lapstone, Schoolmaster, and several other sorts were turned up, none of which had escaped the malady; but of St. Patrick, of which several roots were examined, not one Potato was found to be affected in the slightest degree. This Potato is very prolific; the tubers are very large, well-shaped, and excellent for eating purposes. St. Patrick is an American variety, sent out last year in England for the first time, and it will probably be

Fig. 46.

largely grown when it is better known by English, Scotch, and Irish cultivators. Many other crops beside those mentioned are to be found in the vegetable department, and all are in a satisfactory and flourishing condition. The soil, which is light and open, is well adapted for seed-growing, and all "rogues" among the seed beds are dragged out unmercifully, the utmost care being taken to keep the stocks select.

And now we turn to the flowers, which are grown in large squares. Here a splendid bed of the blue Viola Magnificent, there a mass of pink Saponaria, and in the background large masses of Malope, Bartonia, Sweet Peas, and other showy and tall-growing annuals attract attention. A splendid bed of Indian Pinks, the flowers being of exceptional size and richness of colour. Nearly all are double, few, if any, being inferior, while some are decidedly better than the flower represented in fig. 46. For beds, borders, and cut flowers these easily grown varieties are very valuable. A bed of the beautiful French hybrid Leptosiphons, delightful little flowers of almost every shade, was a sparkling mass of colour. By the side of these are a fine collection of Ten-week Stocks, the flowers being of great size and nearly all double. Yonder is a bed of Nasturtium King of Tom Thumbs, the rich scarlet flowers forming a strong contrast to the beds of blue and yellow bedding Violas by their side. Near the latter are Antirrhinums, a fine selection of moderate growth, intermediate between the major and Tom Thumb types, and a bed of the pretty Viscaria oculata, one of the best of hardy annuals for either autumn or spring sowing. Tropæolum Lobbianum fulgens growing sturdily to the height of 4 feet and trained up stakes is very beautiful, and a dwarf variety selected from it is highly promising. Mignonette is largely grown, Miles' Spiral, Giant Red, Pyramidal, and others, some of the spikes being

15 inches in length. Carnations from seed are exceptionally fine; one plant raised from seed produces ten times more flowers than the florists' varieties from layers, and where large quantities of cut flowers are in request seedling Carnations should not be forgotten. Nearly all the flowers are double, and the colours are rich and varied. One variety—Grenadin—has proved so valuable for its earliness and richness that it is being increased as freely as possible. Larkspurs, Clarkias, Canterbury Bells, including the new rose calycanthema, white Candytuft like masses of snow, Lobelias raised from cuttings, and other showy flowers are there that we cannot enumerate. We must not forget to mention a plantation of the New Japanese Irises—gorgeous varieties that will find their way largely into British gardens. They have just ceased flowering, but it is something to see that their growth is as free as their flowers are fine. The true old Brompton Stock is also here, a grand variety for both pots and borders. Here, as among the vegetables, all is neatness and regularity. Mr. Newby has made many good selections of both flowers and vegetables, and in due time when all the land is under cultivation the proprietors of Langley Farm will no doubt have reason to regard it as amongst their most important acquisitions.

ARAUCARIA IMBRICATA IN SCOTLAND.

WHILST spending an agreeable holiday with some companions at a friend's house in the Glenkens—a district of Kirkcudbrightshire—we were invited by Mr. France, the manager on Mrs. Yorstorm's estate of Ballingear near Dalry, to inspect the grounds, which gave us an opportunity of seeing what we had often heard about, and what is considered in the district as the finest Araucaria in Britain. Certainly it was by far the best specimen of the kind we had ever seen. A note was taken of the measurements, which can be relied upon, and it may interest your readers to have a knowledge of the dimensions. Height, 38 feet; girth at 3 feet from the ground 5 feet, at 5 feet from the ground 4 feet 1 inch. Circumference of the lowest branches which trail along the ground, 76 feet—curiously enough double its height. Its chief beauty lies in its extreme healthy condition, not a flaw from top to bottom. We forgot to ask if it had ever borne any cones. Adjacent is another, all but as fine as that described, and near to is a very fine specimen of the Wellingtonia. Beside a small lake is a Birch 7 feet in girth and of considerable height. There are besides many fine trees growing here and there through the grounds of great rarity. Any of your readers who may have a wish to inspect these Araucarias will, I am sure, receive every attention from Mr. France; and I am certain a visit to Bullengear will be thought by most to be a treat of no ordinary kind, as it is so delightfully situated, and embraces nearly every adjunct of Scottish scenery—hills, dales, lochs, rivers, woods, glens, &c.—F. R.

THE PARKS OF LONDON.—No. 1.

WITHOUT the parks the great metropolis would be deprived of one of its finest features and striking and valuable characteristics; and without the high keeping of those parks, and the diversity and attractiveness of their floral adornment, they would fall far short of their present and richly deserved popularity. The cost of maintenance of these parks is applied to a purpose in every way worthy, and in more than one respect immediately beneficial. They conduce to the health and education of the hundreds of thousands who visit them annually, and through the horticultural press exert a salutary influence on gardens large and small in every district of the kingdom. They are managed by men of skill and taste, who, by their devotion to their duties and the excellence of their work, are worthy of every encouragement by that department of the Government under which they are placed. Hundreds of gardeners visit the parks annually; but as the great majority of them are unable to do so, some description of the more prominent beds will not be unacceptable, commencing with

BATTERSEA PARK.

Not only is the popularity of this extremely diversified and highly picturesque Park maintained, but appears to be ever increasing. It has never been so largely attended as during the present summer, and never was it more deserving of patronage. Owing to the great variety of plants employed there has been something to attract throughout the season, but the Park is perhaps just in the zenith of its beauty now. It is very easy to denounce any particular style of decoration—carpet bedding for instance, and the practice is rather common, especially by those who are not able to carry out the mode themselves. It is also too common to represent that this style of embellishment is almost exclusively practised in the parks. This is decidedly not the case at Battersea, where carpet beds have a comparatively small part

in the arrangements. There are less than a dozen of those beds, and certainly not one too many for the crowds which admire them; in fact, a greater extent of ground is occupied with hardy border and herbaceous plants than with carpet beds, and it must be added well occupied. Early in the summer, June and July, the Funkias made a fine display, their foliage and flowers being alike beautiful. They are planted in broad bands round the margins of the beds, in lines in front of the shrubberies, at the base of shrubs, and dotted about in irregular groups on the lawn. All the best forms are included; the plants are well grown, and their effect was very beautiful. These plants should be more largely grown in gardens. They are quite hardy, and like deep rich soil. Delphiniums were splendid in their season. They are grand park plants, and may with advantage be increased, as also might Foxgloves, which have such a fine effect amongst or near shrubs. Near the east entrance to the Park the beds of Moss Roses have been a great success, and the fragrant masses of the old Provins Cabbage have been much admired. The Rose beds at the western end have also been strikingly beautiful. The association with the dark varieties, such as Crimson Bedder with *Lilium candidum*, proved a singularly happy arrangement. The herbaceous border has been gay throughout, one of the most effective plants at the present time being *Rudbeckia Newmanni*. Lines 100 yards or more in length of *Anemone japonica* and *alba* now in full beauty arrest the attention of all visitors, and associated with the *Anemones* fine clumps of *Lilium tigrinum Fortunei* are both elegant and rich, while also at the present time beds of Phloxes are grand. The variety is The Queen, and the pure white trusses are of immense size. This Phlox, and indeed many others, should be grown in all gardens. Suffice has been said to show that something more than carpet beds is to be seen at Battersea Park. Carpet beds are, however, represented, and they perhaps receive the lion's share of public attention, judging by the crowds which cluster round them on Sunday nights. Some of these beds are gay, yellow and red predominating. Some are sober, green prevailing; while others are chaste yet cheerful, and extremely neat. "The parks," as Mr. Roger justly observes, "are for the public," and he can only satisfy the necessarily varied tastes by a great dissimilarity of designs and colours. Carpet beds cannot be adequately described without diagrams, yet an idea may be conveyed of one or two of them, and the plants that are employed.

A circular bed attracts primary notice, as it is planted with the new *Alternanthera paronychioides major aurea* as a groundwork. This very distinct variety originated at Battersea and is not in commerce. The prevailing colour is reddish yellow, or almost the "old gold" colour that is fashionable this year. It is totally dissimilar from all others of the genus, grows freely, and produces an uniformly level surface. A scroll of the dark *A. versicolor grandis* effectively occupies the centre of the bed, small circles of *Mentha* being formed in the curves of the scroll, each containing a small variegated *Yucca*. The bed is surrounded with a band, richly coloured, of *Alternanthera amoena*, the raised margin being covered with the silvery *Sedum acre elegans*. This bed is bright yet chaste, and the workmanship is faultless. An adjoining bed is of more sober aspect, the groundwork being of *Mentha*, with three spatulate panels of *Alternanthera* and angles of *Leucophyton Brownii*, the margin being similar to that of the other bed, the arrangement being considered very neat. It were useless attempting a description of the "carpet rug" and "coffin" beds, which are so warmly discussed by the visitors. For some tastes the yellow is too pronounced, but by others, and especially ladies, it is admired for the reason above stated—namely, that it is "fashionable." Far more elegant than these flat beds are some large oblongs. It will suffice to refer to one of them, a bed perhaps 24 feet long by 8 wide. Along the centre are five circles 3 feet in diameter, each containing five or six plants similar to those which take prizes at exhibitions for dinner table decoration. Very graceful in some of the circles are the groups of *Dracena gracilis*, which contrast admirably with other groups of *Pandanus Veitchii*; again, groups of *Ficus rubiginosa* mixed with *Acacia lophantha* are admired, and *Fuchsia Golden Treasure* associated with *Cuphea platycentra* is a happy combination. The groundwork of these circles is of *Mentha* enclosed with a narrow streak of Golden Feather and a broad and fine band of *Alternanthera amoena*. The groundwork between the circles is of Golden Feather, the bed being bounded with *Alternanthera* and margined with *Echeverias*. Another of these beds with a groundwork of *Nierembergia gracilis* has been very pretty as covered with thousands of delicate flowers. The large scroll or S-shaped beds have never looked so well as they do this year. The end circles are filled with *Amaranthus melancholicus ruber*, which is so rich when in good condition, as it is now, from which rise slender and healthy *Cordylines*. The scroll portions of the beds are carpeted in panels

with dwarf Palms, &c., at intervals, which impart to the beds a free and pleasing appearance. A bed of tall variegated *Yuccas* in a groundwork of *Colcuses*, and another of tall *Cordylines* similarly carpeted and appropriately edged, find many admirers. A large round bed carpeted with *Lobelia White Brilliant* and planted with specimen *Dasyliirions* is most chaste. This is the best of white *Lobelias*, and seen in good condition meets with general approval. In striking contrast a still longer bed adjoining is filled with striped *Petunias* dotted with stately plants of *Brugmansia Knightii*. At the margin of the *Petunias* are some fine Cockscombs, the bed being margined with a dwarf scarlet *Tropaeolum*. The *Petunias* (Hender's strain) have been very gay, but are now losing their markings. The beauty of the bed, however, will be maintained by the *Brugmansias*, which are producing their large trumpet-shaped flowers freely. A still larger and very imposing bed some distance from the path is chiefly planted with *Eucalyptus globulus*, quite a plantation of Blue Gums, the young trees being about 8 feet high. They are surrounded with a band of a tall scarlet *Pelargonium*, next to which is a fine row of *Viola Blue Bell* margined with *Gazania splendens*. This arrangement has been most effective for some weeks past.

It may usefully be recorded that the *Viola* named is the most satisfactory of all the blue or purple varieties that have been grown in the Park. It is of excellent habit, very floriferous, and has continued in beauty throughout the season. Another variety, *Duchess of Teck*, is similarly free; it is a pale lavender blue, and the two beds of it at the west end of the Park have had hosts of admirers. Mr. Roger considers these the two most useful bedding *Violas* in his possession. The *Eucalypti* are raised from seed annually, the plants intended for next year's planting being now about a foot high and established in pots. Such free luxurious specimens as those above referred to have an unique effect, the foliage both in form and colour being totally dissimilar from that of any other trees or plants in the park.

A group of *Aralia papyracea* margined with *Salvia argentea* appears to great advantage, the growth of the plants being unusually luxuriant. Another subtropical plant is in splendid condition, *Polymnia grandis*, with magnificent deeply lobed leaves 2 feet long and 1½ in diameter. No ornamental-foliaged plant exceeds this in beauty, and few equal it. It is raised from cuttings. The plants are 6 feet apart in a groundwork of *Heliotropes*. Another subtropical exceptionally fine is *Solanum macrophyllum*, the leaves being of immense size; the groundwork of this bed is of *Verbena venosa* and *Lantana*, margined with *Sempervivum canariense major*, one of the finest of the succulents. A bed of *Ricinus sanguineus* rising from a mass of *Veronica Andersonii variegata*, edged with *Ageratum Countess of Stair*, is both stately and pleasing; and the darker *R. Gibsonii* associated with *Chrysanthemum coronarium* and edged with *Heliotropes* is excellently placed and telling. *Solanum laciniatum*, it may be observed, is affected in apparently the same manner as Potatoes, and the plants have to be removed.

Some mixed beds of choice foliage and flowering plants afford acceptable variety, and merit and receive the close examination of visitors. In one of these beds *Lilium auratum* is remarkably fine, *Tigridia pavonia* very gay, *Kalosantes coccinea* with glowing heads, *Begonias* both elegant and rich, and *Agapanthuses* have been prominent, the variegated foliage of *Eurya latifolia variegata* cheerful, and *Sonchus laciniatus* graceful. *Desmodium pendulæflorum* is just commencing flowering; and *Abutilons Lemoinei* fine yellow, *Boule de Neige*, and *Darwinii tessellatum* contribute to the general effect. *Abutilon brasiliense*, too, is represented by several fine plants; the leaves are very large, cordate, exceeding a foot in diameter, and faintly veined with pale yellow. A bed of this plant is edged with *Artemisia Stelleriana*, and the elegant *A. judaica* is employed in some of the arrangements. This is a highly distinct silvery-foliaged plant, and very suitable as a hanging plant for vases.

Some of the marginal plants in the raised beds or borders fronting the shrubs give a fine finish to the picturesque nooks that abound in the Park. A row of a fine scarlet *Pentstemon* a striking, and more sober in effect, is the small yet elegant *Fuchsia pumila*. The crimson pendent inflorescence of *Love-lies-bleeding* (*Amaranthus caudatus*), drooping over a curved line of a silver bicolor *Pelargonium*, has a pretty effect; but perhaps the finest of the edgings are of the old variegated *Pelargonium Manglesii*. These—as backed with Mrs. Holden *Pelargonium*, pink, large trusses, and in one instance margined with *Convolvulus mauritanicus*—are extremely chaste. The *Convolvulus*, however, cannot be seen to advantage except early in the day, its beautiful satiny blue flowers being closed in the evening.

Cannas are in fine condition this year, the bright sun overhead of the past three weeks and copious applications of water to the

roots suiting them admirably. Of the yellow-flowering varieties *Annei grandiflora* is perhaps the best, the flowers being large and clear. *Gladioliflora* is an excellent orange-red variety with good foliage; *Secrétaire Kopner*, rich scarlet, is rare, early, and good; *Van Houttei* is one of the best of the dark-foliaged; and *Peruviana* the finest green-leaved variety, with long spikes of bright scarlet flowers. Although *Cannas* will generally survive the winter if left in the beds and protected with manure and leaves, it is found the best practice to take them up and winter them under the stages of plant houses in cocoa-nut fibre or leaf soil.

Pelargoniums are also flowering with great freedom, and the beds have recently been very gay. If a large bed of an intense glowing crimson is wanted, obtain a stock of *Charles Schwind*. If a smaller bed of the same colour is coveted, plant *Henry Jacoby*. Nothing can surpass them in richness as seen in the Park. There is an abundance of good pink bedders. Perhaps the finest bed is of *Mrs. Ward*, rosy pink; but *Mrs. Lancaster*, salmon pink, is excellent, and equally so but paler is *Mrs. Quilter*. For producing a mass of glowing pink the old *Cleopatra* must not be despised. A bed of it near the western entrance is fine, and the visitor will also notice there a charming mixture of the veteran *P. Manglesii* above mentioned, and a dwarf scarlet *Tropæolum*; he cannot fail to notice also and admire in the same design edgings of the pink *Lobelia Omen*. Of the *Nosegay* Pelargoniums *Waltham Seedling* wears wonderfully well; indeed, for continuous flowering it is unsurpassed, if equalled. Of *Bonfire* there are also brilliant masses, and *Fire King* is very good. One of the best of the rather tall scarlets—large in truss and bright in colour, fine for large beds and borders—is *Montrouge*, and the best dwarf is probably *Vesuvius*; but *Little David*, a miniature *Tom Thumb*, must not be forgotten.

In another portion of the Park are long lines of superior double yellow and white varieties of *Chrysanthemum coronarium* that show to great advantage. A dwarf yellow French *Marigold* is largely employed, and winding lines of *Calceolarias*, *Gains's Yellow*, are not too bright for their position in front of sombre masses of shrubs. In front of the *Calceolarias* dwarf *Ageratums* are extremely beautiful—*Countess of Stair* and *Cupid* (Ireland and Thomson), the latter is dwarfer and darker than the former, but both are good. Of the blue *Lobelias* *Mazarine Gem* and *Brighton* are perhaps the best, a line of the former being splendid. *Dahlias* are just coming into beauty, and seedling *Verbena*s mixed with *Mignonette* make a sweet and pretty border.

Such is a passing glance of the most noticeable plants in this Park, but one other feature remains to be briefly noticed—the "Wilderness." This is a new feature near the north-eastern entrance, and is not yet opened to the public. It is composed of mounds and dells, high banks, and curving walks. At the bottom of the dells the variegated *Comfrey* (*Symphytum asperrimum* variegatum) is effective, and on the banks there will in a year or two be a grand display of the valuable *Hydrangea paniculata grandiflora*. The *Aralia*-like plant *Dimorphanthus mandshuricus* is flowering freely in this corner of the Park, which is sure to be much patronised by the public when it is opened.

Battersea Park is worthy of the country, most creditable to Mr. Roger, his foreman Mr. Hart, and other assistants; and that it is valued by the public sufficient proof is afforded by the fact that it is not unusual for from thirty-five thousand to forty thousand people to enter the subtropical garden during fine Sunday evenings.

KENNINGTON PARK.

This small but gay and much-crowded Park in the south of London is also under the superintendence of Mr. Roger, and is admirably kept by Mr. Brown, a practical gardener and industrious man. No lawns and terraces can be kept neater than they are here, and no beds and borders can be imagined more bright and cheerful. The position is not well adapted for subtropical plants, and only a few down the centre of the large sunken panels are occupied with ornamental-foliaged plants—*Cannas*, *Variegated Maize*, *Perillas*, *Centaureas*, &c.—in mixture, but the beds of flowering plants on the terrace are in the most satisfactory condition. Carpet beds are comparatively limited, there only being eight of these—the corner beds on two terraces, but they are excellent of their kind, one or two of them being very superior. In one of these beds a scroll of *Sedum acre elegans* surrounded with a streak of yellow (*Golden Stellaria*) in a rich ground of *Alternanthera magnifica*, with cushions of *Mentha* and raised succulents, a fine close green band of *Herniaria glabra* lined with *Kleinia*, then another thin line of yellow, and an edging of *Echeverias*, is an arrangement that should be seen by all admirers of this style of decoration. The colours are so well balanced and the design represented with such precision and accuracy as to render the bed in the highest degree artistic. No one can justly say that

carpet bedding is overdone in this Park, and it is incontestable that the few beds are greatly admired by thousands of visitors. Amongst the Pelargoniums the dark varieties *John Gibbons*, *General Outram*, *A. F. Barron*, and *Rev. J. Atkinson* are glowing masses. *Cerine* is a lively pink, and *Lizzie Brooks* a fine soft scarlet. Most of the beds are edged with a silver bicolor variety and edged with *Lobelia Porcelain Brilliant*, a fine variety in splendid condition. In the centre of the terrace the formality of the arrangement is broken by the Ivy-clad cottage and the raised banks of flowers sloping from the hedge which partly surrounds it. One of these banks is covered thickly with *Pansies*, *Phlox Drummondii*, and *Mimulus* in mixture, with blocks of *Zinnias* here and there, and a line of these flowers next the hedge. The other bank has a groundwork of *Letunias*. The double *Zinnias* obtained from a private source are splendid, equalling bouquet *Dahlias*, those from purchased seed being poor in comparison. A very long line of *Anemone japonica* along the southern boundary of the Park is very beautiful, and another extensive flower garden in a sunken panel is extremely gay with *Calceolarias*, *Perilla*, Pelargoniums *Edward Sutton*, scarlet, and *Mrs. Holden* pink, and *Blue Bell Viola*. Many thousands of plants are employed in this arrangement, and all have done well and flowered freely. Some mixed beds—*Iresine Lindenii* associated with the golden-foliaged Pelargonium *Robert Fish*, and the *Duchess of Teck Pansy*; and *Iresine*, a silver-leaved Pelargonium, and *Verbena venosa*, have a pleasing effect. Thus nearly all styles of flower gardening are represented in this Park, while the shrubs on the south side show what can be done by timely thinning, and allowing each shrub space to form a handsomely formed specimen. Such borders have a far better effect than overcrowded masses of evergreens as are too often seen in public and private gardens. *Kennington Park* is much and deservedly valued by the inhabitants in its locality, and well it may be, for few aristocratic gardens are more gay and in better order than this pleasant enclosure.

FIRM OR LOOSE POTTING.

A FEW remarks on potting may interest some readers of the Journal. I have often noticed the difference in the potting of plants from the Continent and those grown in England. The former are potted loosely and in a light soil. Take, for instance, *Azaleas* and *Camellias*. While those from the Continent are potted lightly in decayed matter, in England we generally find *Azaleas* in peat, and *Camellias* in a mixture of peat and loam, both potted firmly. Plants sent here from Belgium or elsewhere appear as vigorous as English plants, though I doubt if they are as suitable for this climate. We are told that firm potting adds to the life of plants. I have heard that the ground in New Holland is not nearly so firm as it has been represented to be, yet many can remember how firm the *Barnet* plants were potted in days past, and they were all that could be desired.
